California Department of Fish and Wildlife Incidental Take Permit for Long-Term Operation of the State Water Project in the Sacramento-San Joaquin Delta, March 2020.

B. Port Hueneme Lease of Ventura Table A

Source of Supply

Metropolitan has a right to delivery of up to 1,850 AF of Table A from the Ventura County Watershed Protection District (Ventura), one of 29 SWP contractors, via a sublease agreement with the Port Hueneme Water Agency (Port Hueneme). United Water Conservation District, one of three agencies holding a contract right to Ventura Table A supply, leases this portion of their total 5,000 AF of Table A to Port Hueneme, who in turn subleases the Table A to Metropolitan. The long-term lease is a condition of the 1996 annexation of the Port Hueneme service area to Calleguas Municipal Water District and Metropolitan.

Expected Supply Capability

The amount of supply available to Metropolitan under the long-term lease is up to 1,850 AF of Ventura Table A. This water supply is in addition to Metropolitan's Table A, and the amount available each year is determined by the SWP allocation, with 1,850 AF available at a 100 percent allocation.

Rationale for the Expected Supply

The DWR estimates the amount of supplies that are available each year. Metropolitan uses a forecasting method for SWP deliveries based on historical patterns of precipitation, runoff and actual deliveries of water.

Historical Record

Metropolitan has taken delivery of Port Hueneme Lease water since 1997. These supplies are delivered to Metropolitan from the West Branch of the California Aqueduct and have ranged from 93 AF under a 5 percent allocation to 1,850 AF under a 100 percent allocation.

Written Contracts or Other Proof

Port Hueneme Water Agency Annexation. By Minute Item 41728, dated January 9, 1996, Metropolitan's Board adopted Resolution 8487 granting the concurrent annexation of Annexation No. 32 to Calleguas Municipal Water District and The Metropolitan Water District of Southern California, and fixing Metropolitan's terms and conditions for the annexation.

1996 Sublease Agreement. The Port Hueneme and Metropolitan executed a sublease agreement to facilitate annual delivery to Metropolitan of up to 1,850 AF of Ventura Table A that is leased to Port Hueneme by United Water Conservation District.

Financing

Financial obligations to DWR related to the 1,850 AF Port Hueneme Lease supply, including variable transportation charges for delivery, remain the responsibility of the Ventura County Watershed Protection District.

Federal, State, and Local Permits/Approvals

DWR is responsible for acquiring, maintaining, and complying with numerous Federal and State permits for operation of the SWP.

C. Desert Water Agency/Coachella Valley Water District/Metropolitan Water Exchange and Advance Delivery Programs

Source of Supply

The Desert Water Agency (DWA) and CVWD, both in Riverside County, have rights to SWP deliveries, but do not have any physical connections to the SWP facilities. Both agencies are adjacent to the CRA. For DWA and CVWD to obtain water equal to their SWP allocations, Metropolitan has agreed to exchange an equal quantity of its Colorado River water for DWA and CVWD's SWP water. DWA has a SWP Table A contract right of 55.75 TAF per year, and CVWD has a SWP Table A contract right of 138.35 TAF per year, for a total of 194.1 TAF per year. Additionally, CVWD has a long-term water supply agreement for 9.5 to 16.5 TAF annually from Rosedale Rio-Bravo Water Storage District.

Expected Supply Capability

Under the existing agreements, Metropolitan provides water from its CRA to DWA and CVWD in exchange for SWP deliveries. Metropolitan can deliver additional water to its DWA/CVWD service connections, permitting these agencies to store water. When supplies are needed, Metropolitan can then receive its full Colorado River supply, as well as the SWP allocation from the two agencies, while the two agencies can rely on the stored water for meeting their water supply needs. The amount of DWA and CVWD SWP Table A water available to Metropolitan depends on total SWP deliveries and varies from year to year.

In addition to their Table A and long-term water supplies, DWA and CVWD, subject to available capacity, may take delivery of SWP supplies available under Article 21, the Turn-back Pool Program, and non-SWP water supplies they may acquire and convey through the SWP facilities. These other supplies are delivered to DWA and CVWD by exchange with Metropolitan in the same manner as Table A deliveries. DWA and CVWD are participants in the Yuba Dry Year Water Purchase Program. Additionally, DWA participated in the 2009 Drought Water Bank and the 2015-2016 Multi-Year Water Pool Demonstration Program.

Rationale for the Expected Supply

The DWR estimates the amount of supplies that are available each year. Metropolitan uses a forecasting method for SWP deliveries based on historical patterns of precipitation, runoff and actual deliveries of water.

<u>Historical Record</u>

DWA and CVWD Exchange Program is currently in operation. The Advance Delivery Agreement has been in place since 1984. Since 1973, Metropolitan has been taking delivery of these agencies' SWP Table A water and has provided equivalent water to those agencies from Metropolitan's Colorado River supplies. Metropolitan has also been delivering water in advance of the amount needed under the exchange agreements. With water having been delivered in advance, Metropolitan can reduce deliveries to DWA and CVWD as needed. The Advance Delivery Account is a key tool for managing abundant SWP supplies. In 2017, Metropolitan managed an 85 percent SWP allocation in part by making 245 TAF of advance deliveries, bringing the account balance up to 325 TAF by the end of the year.

<u>Written Contracts or Other Proof</u>

<u>1967 and 1983 Water Exchange Contract and Agreements.</u> The DWA and CVWD Program is currently in operation. The DWA and CVWD water exchange contract has been in place since 1967, was amended in 1972, and was modified with execution of additional agreements in 1983.

1984 Advance Delivery Agreement. The Advance Delivery Agreement allows Metropolitan to supply DWA and CVWD with Colorado River water in advance of the time these agencies are entitled to receive water under the exchange agreements. In future years, Metropolitan can recover this water by reducing its deliveries under the exchange agreements.

The 2003 Exchange Agreement. DWA, CVWD, and Metropolitan executed the 2003 Exchange Agreement under which Metropolitan transferred 88.1 TAF and 11.9 TAF of its SWP Table A water to DWA and CVWD, respectively, reducing Metropolitan's Table A volume from 2,011.5 TAF to 1,911.5 TAF. The 2003 Exchange Agreement became operational in calendar year 2005 with the execution of letter agreements among DWA, CVWD, and Metropolitan governing its implementation. The exhibits to the November 9, 2004, and November 19, 2007, letter agreements also modify certain provisions of the Water Exchange Contract and Agreements and the Advance Delivery Agreement.

November 2012 Letter Agreement. CVWD and Metropolitan executed the letter agreement to deliver non-SWP water in exchange for Colorado River water under which CVWD arranged for the delivery of up to 16.5 TAF per year of water to Metropolitan provided by Rosedale-Rio Bravo Water Storage District to CVWD. Metropolitan delivers to CVWD an equal amount of Colorado River water.

2019 Amended and Restated Agreement for Exchange and Advance Delivery. In December 2019, CVWD, DWA, and Metropolitan executed an amendment to the exchange and delivery agreements in order to provide greater certainty for water supply and financial planning, simplify implementation of the exchange, provide Metropolitan with additional revenue, and improve dry-year water supply reliability.

Financing

The funds for deliveries under this Program are included in Metropolitan's O&M budget and Long-Range Finance Plan (referenced above).

Federal, State, and Local Permits/Approvals

DWR is responsible for acquiring, maintaining, and complying with numerous Federal and State permits for operation of the SWP.

July 26, 1983, CVWD Negative Declaration, Whitewater River Spreading Area expansion Phase 1.

February 1983, DWA Final EIR for the proposed extension of time for utilizing Colorado River water to recharge the upper Coachella Valley groundwater basins to the year 2035, Volume I and II, April 1983, Volume III.

September 2002, Final Program EIR for Coachella Valley Water Management Plan and SWP Entitlement Transfer was certified by CVWD on October 8, 2002.

In 2020, an application was filed with the Bureau of Land Management to renew and amend the existing Right-of-way grant for groundwater replenishment purposes on the Whitewater River Groundwater Replenishment Facility.

D. Semitropic Water Banking and Exchange Program

Source of Supply

The agreement between Semitropic Water Storage District (Semitropic) and Metropolitan was executed in February 1994. Semitropic obtains water from the SWP through its contracts with the Kern County Water Agency. SWP supplies irrigate an area of 161,200 acres within Semitropic's service area. When this surface water is not available, these growers withdraw water from the underlying aquifer. The agreement between Semitropic and Metropolitan allows Metropolitan to make use of 350 TAF of storage in Semitropic's groundwater basin. In years of plentiful supply, Metropolitan can deliver available SWP supplies to Semitropic through the California Aqueduct. During dry years, Metropolitan can withdraw this stored water. Five other banking partners participate in this Program and use 650 TAF of storage in Semitropic's groundwater basin.

Expected Supply Capability

The Semitropic-Metropolitan Program provides Metropolitan with the capacity to store up to 350 TAF of water under the current agreement. During dry years, Metropolitan can recover its stored water through a combination of direct pumping of the groundwater and delivery of Semitropic's SWP Table A water in the California Aqueduct. In 2014, Metropolitan amended the program to increase the return yield by an additional 13.2 TAF per year that has since been reduced to 6.7 TAF. The minimum annual yield available to Metropolitan from the program is currently 38.2 TAF, and the maximum annual yield is 229.77 TAF depending on the available unused capacity and the SWP allocation. The average annual supply capability for a single dry year similar to 1977 is 45 TAF. For a five-year consecutive drought condition similar to the period of 1988-1992, the expected supply capability is 50 TAF.

Rationale for the Expected Supply

Historical Record

The Semitropic-Metropolitan Water Banking and Exchange Program has been operational since 1994. With existing agreements, it will continue to operate over the term of 41 years (1994 to 2035). By the end of 2020, the program had 261 TAF in its storage account.

Written Contracts or Other Proof

1992 Turn-in/out Construction, Operation and Maintenance Agreement. This Agreement was executed in 1992 by DWR and Semitropic to allow construction, operation, and maintenance of the Semitropic California Aqueduct Turn in/out.

1993 Temporary Semitropic-Metropolitan Water Banking Agreement. This Agreement was executed in February 1993 by Semitropic and Metropolitan to allow the storage of available Metropolitan supplies in advance of execution of the long-term agreement.

1994 Semitropic/Metropolitan Water Banking and Exchange Agreement. This Agreement was executed in December 1994 by Semitropic and Metropolitan to implement the program for a 41-year term (1994-2035).

1995 Point of Delivery Agreement. This agreement, with DWR, Kern County Water Agency, and Metropolitan, allows Metropolitan to divert water from the California Aqueduct into Semitropic's service area.

1995 Introduction of Local Water into the California Aqueduct. This agreement, with DWR, Kern County Water Agency, and Semitropic, allows Metropolitan to receive water from the program into the California Aqueduct.

2014 Amendment to Increase Program Yield. The amendment increased Metropolitan's minimum return yield by 13,200 acre-feet per year.

Financing

Metropolitan's O&M budget (referenced above) includes payments for the Semitropic Program.

Federal, State, and Local Permits/Approvals

Final EIR. Semitropic acting as the lead agency under CEQA and Metropolitan acting as a responsible agency jointly completed the EIR for the Program. The EIR was certified by Semitropic in July 1994 and adopted by Metropolitan in August 1994.

Regulatory Approvals. All regulatory approvals are in place, and the program is operational.

E. Arvin-Edison Water Management Program

Source of Supply

The Arvin-Edison Water Storage District (Arvin-Edison) manages the delivery of local groundwater and water imported into its service area from the Central Valley Project's (CVP) Millerton Reservoir via the Friant-Kern Canal. The surface water service area consists of 132,000 acres of predominantly agricultural land, and to a minor degree, municipal and industrial uses. It is situated in Kern County. Arvin-Edison operates its supplies conjunctively, storing water in the underlying aquifer when imported supplies are available and withdrawing that water when the availability of imported supplies is reduced. In 1997, Metropolitan entered into an agreement with the Arvin-Edison Water Storage District. The agreement allows Metropolitan to store available water in Arvin-Edison's groundwater basin, either through direct spreading operations, or through deliveries to growers in Arvin-Edison's service area. Similar to Arvin-Edison's own usage, this previously stored water could be withdrawn when the availability of imported supplies to Metropolitan is reduced.

Expected Supply Capability

The Arvin-Edison/Metropolitan Program provides Metropolitan with the capacity to store up to 350 TAF of water under the current agreement. During dry years, Metropolitan can recover its stored water either through direct pumping of the groundwater or through exchange. Based on the terms and conditions of the program agreement, the return of water to Metropolitan ranges from a minimum of 40 TAF per year (peak 4-month summer period) up to 110 TAF (over a 12-month period). Metropolitan staff are currently working to overcome a new challenge of detections of 1,2,3-trichloropropane (TCP) above the Maximum Contaminant Level (MCL) of five parts per trillion (ppt) in wells that are part of the Arvin-Edison/Metropolitan Program. These levels of TCP impact Metropolitan's ability to put water and take return water under that program. As a result, Metropolitan has temporarily suspended operation of the program until the water quality concerns can be further evaluated and managed.

Rationale for the Expected Supply

Historical Record

The Arvin-Edison/Metropolitan Water Management Program has been operational since 1997. With existing agreements, it will continue to operate over the term of 38 years (1997 to 2035). By the end of 2020, the program had 142 TAF in its storage account.

Written Contracts or Other Proof

1997 Arvin-Edison/Metropolitan Water Management Agreement. This Agreement was executed in December 1997 by Arvin-Edison and Metropolitan to implement the program for a 30-year term (1997-2027).

1998 Turn-in/out Construction and Maintenance Agreement. This Agreement was executed in 1998 by DWR, Kern County Water Agency, Arvin-Edison, and Metropolitan to allow construction, operation and maintenance of the Arvin-Edison California Aqueduct Turn in/out.

1998-2002 Water Delivery and Return Agreements. These agreements, with DWR, Kern County Water Agency, Arvin-Edison, and Metropolitan, allow Metropolitan to divert water from, and introduce water to, the California Aqueduct.

2004 Point of Delivery Agreement. This agreement, with DWR, Kern County Water Agency, and Metropolitan, allows Metropolitan to divert water from the California Aqueduct into Arvin-Edison's service area.

2004 Introduction of Water into the California Aqueduct. This agreement, with DWR, Kern County Water Agency, and Arvin-Edison, allows Metropolitan to receive water from the program into the California Aqueduct.

2007 First Amended and Restated Agreement Between Arvin-Edison Water Storage District and The Metropolitan Water District of Southern California for a Water Management Program. This amendment increased the maximum storage level to 350 TAF, extended the agreement term to 2035, and provided for the construction of the South Canal Improvement Project. The project increases the reliability of Arvin-Edison returning higher water quality to the California Aqueduct.

Financing

Metropolitan's O&M budget (referenced above) includes payments for the Arvin-Edison Program.

Federal, State, and Local Permits/Approvals

Environmental Status: A Negative Declaration was completed in 1996.

An Addendum to the 1996 Negative Declaration was completed in 2003.

A Negative Declaration for the Arvin-Edison South Canal Improvement Project was completed in 2007.

Regulatory Approvals: All regulatory approvals are in place, and the program is operational.

F. San Bernardino Valley Municipal Water District Program

Source of Supply

The San Bernardino Valley Municipal Water District Program allows Metropolitan to purchase a dependable annual supply, as well as an additional supply for dry year needs. Under this program, Metropolitan purchases water provided to San Bernardino Valley Municipal Water District (Valley District) from its annual SWP water allocation. Valley District delivers the purchased supplies to Metropolitan's service area through the coordinated use of facilities and interconnections within the water conveyance system of the two districts.

The purchased SWP supply is provided to Metropolitan as direct deliveries of annual SWP water through the California Aqueduct to Metropolitan's service area, as well as deliveries of SWP water to the San Bernardino groundwater basin that will subsequently be delivered to Metropolitan's service area. Under this program, Metropolitan purchases surplus Valley District supplies on a fixed price schedule based on the final SWP allocation each calendar year.

To facilitate the transfer, the program also provides the coordinated use of existing facilities, including the Valley District's Foothill Pipeline and the Inland Feeder, to improve the conveyance capabilities of the delivery of SWP water to the service areas of both districts. The intertie between the Foothill Pipeline and the Inland Feeder has been constructed and was operational as of December 2002. This intertie allows Metropolitan to move SWP water from the East Branch of the California Aqueduct through the Foothill Pipeline and Inland Feeder, into DVL and the CRA. As a result of this intertie, Metropolitan has an alternative conveyance capacity of 260 cfs into Metropolitan's system should an outage occur on the upper section of the Inland Feeder.

Expected Supply Capability

The program changed from the minimum purchase program to a surplus program. Valley District will provide Metropolitan surplus SWP supplies likely in higher than normal SWP allocations. The historical average for the program is expected to be around 13 TAF per year.

Rationale for the Expected Supply

Historical Record

The San Bernardino Valley Municipal Water District Program began operations in 2001 and ended in 2016. Since its inception in 2001, this program has delivered 200 TAF to Metropolitan. Metropolitan and Valley District approved a new Coordinated Operating Agreement in 2021 that will provide Metropolitan surplus Valley District supplies and emergency mutual aid.

Written Contracts or Other Proof

Metropolitan's annual and dry-year supplies from the San Bernardino Valley Municipal Water District Program are based on Metropolitan Board actions and agreements.

2000 Board Approval of Coordinated Operating Agreement. In June 2000, Metropolitan's Board authorized entering into a Coordinated Operating Agreement between Metropolitan and Valley District to develop projects that could provide benefits to both districts through the coordinated use of facilities and SWP supplies.

2000 Coordinated Operating Agreement. The Coordinated Operating Agreement between Metropolitan and Valley District was executed in July 2000.

2001 Board Approval of the Coordinated Use Agreement. In April 2001, Metropolitan's Board authorized entering into the Coordinated Use Agreement for Conveyance Facilities and SWP Water Supplies between Metropolitan and Valley District for the purchase of dependable annual and dry year supplies by Metropolitan.

2001 Coordinated Use Agreement. The Coordinated Use Agreement for Conveyance Facilities and SWP Water Supplies between Metropolitan and Valley District for the purchase of dependable annual and dry year supplies by Metropolitan was executed May 2001. The Agreement is effective as of July 1, 2001, for an "evergreen" term (10-years with automatic annual extensions unless otherwise notified).

2021 Coordinated Operating Agreement. The Coordinated Operating Agreement between Metropolitan and Valley District was approved by Metropolitan's Board in March 2021. The agreement will terminate on December 31, 2035 unless there is an extension of the SWP Contract.

Financing

Metropolitan's O&M budget (referenced above) includes the funds to purchase Program water.

Federal, State, and Local Permits/Approvals

The Program became effective July 1, 2001. An environmental review process and regulatory approval supported implementation.

Final EIR. Final Regional Water Facilities Master Plan EIR dated February 1, 2001, was certified by Valley District, as lead agency, and by Metropolitan, as responsible agency. Notices of determinations were filed by Valley District and Metropolitan on May 29, 2001, and April 18, 2001, respectively.

State Water Contractors' Review. In May 2001, the SWC reviewed and issued a letter supporting the program.

DWR Review. DWR agreed to the program in December 2001.

G. San Gabriel Valley Municipal Water District Program

Source of Supply

The San Gabriel Valley Municipal Water District Program allows Metropolitan to exchange supplies to provide additional water for normal and dry year needs. Under this program, Metropolitan delivers supplies to the City of Sierra Madre, a San Gabriel Valley MWD member agency. In exchange for Metropolitan delivering one acre-foot, San Gabriel Valley MWD returns two acre-feet to Metropolitan in the Main San Gabriel Basin, up to 5 TAF. For any exchange amount less than 5 TAF, Metropolitan purchases the balance of the 5 TAF. The program provides increased reliability to Metropolitan by allowing additional water to be delivered to Metropolitan's member agencies Three Valleys MWD and Upper San Gabriel Valley MWD that rely upon the Main San Gabriel Basin for their supplies.

Expected Supply Capability

The average annual supply capability for a single dry year similar to 1977 is a net 2 TAF. For a five-year consecutive drought condition similar to the period of 1988-1992, the expected supply capability is 2 TAF.

Rationale for the Expected Supply

Historical Record

The San Gabriel Valley Municipal Water District Program began operations in 2013 and is expected to be renewed continually in the future. Since its inception in 2013, the program has completed the exchange and purchase of 30.66 TAF, with a net increase to Metropolitan's supply by an additional 19.5 TAF.

Written Contracts or Other Proof

Metropolitan's dependable annual and dry-year supplies from the San Gabriel Valley Municipal Water District Program are based on Metropolitan Board action and agreement.

2013 San Gabriel Valley MWD Exchange and Purchase Agreement. The agreement between Metropolitan and San Gabriel Valley MWD was executed in September 2013.

2013 Board Approval of the San Gabriel Valley MWD Exchange and Purchase Agreement. In August 2013, Metropolitan's Board authorized entering into the agreement with San Gabriel Valley MWD.

Financing

Metropolitan's O&M budget (referenced above) includes the funds to purchase water.

Federal, State, and Local Permits/Approvals

The Program became effective as of September 2013. An environmental review process supported implementation.

CEQA Compliance. The proposed action involved an exchange and purchase agreement associated with the leasing, licensing, and operating of existing public water conveyance facilities with negligible or no expansion of use and no possibility of significantly impacting the physical environment.

H. Antelope Valley East Kern Water Agency Exchange and Storage Program

Source of Supply

The Antelope Valley East Kern Water Agency (AVEK) Program allows Metropolitan to both exchange and store SWP supplies to provide additional water for normal and dry year needs. Under this program, AVEK provides Metropolitan its unused SWP supplies. For every two acre-feet provided by AVEK, Metropolitan will return one acre-foot. The exchange program when implemented is expected to deliver 30 TAF over ten years, with 10 TAF available in dry years. At this time, the Department of Water Resources has not approved the exchange program element. Metropolitan has storage capability in the groundwater basin, with a capacity of 30 TAF, and a dry year return capability of 10 TAF.

Expected Supply Capability

The average annual supply capability for a single dry year similar to 1977 is 3 TAF for each program. For a five-year consecutive drought condition similar to the period of 1988-1992, the expected supply capability is 4 TAF for each program.

Rationale for the Expected Supply

Historical Record

The AVEK Program started providing benefits in 2017. By the end of 2020, the program had 27 TAF in its storage account.

Written Contracts or Other Proof

Metropolitan's dependable annual and dry-year supplies from the AVEK Exchange and Storage Program are based on Metropolitan Board action and proposed agreement.

2015 Board Approval of the AVEK Exchange and Storage Agreement. In November 2015, Metropolitan's Board authorized entering into the agreement with AVEK.

Financing

Metropolitan's Board authorized up $16.6 million for the program with additional funds, if needed, from Metropolitan's O&M budget (referenced above).

Federal, State, and Local Permits/Approvals

The storage element of the Program became effective after the agreement was executed in 2016. The Department of Water Resources has not approved the exchange program element at this time.

CEQA Compliance. The proposed action involved an exchange and purchase agreement associated with the leasing, licensing, and operating of existing public water conveyance facilities with negligible or no expansion of use and no possibility of significantly impacting the physical environment.

I. High Desert Water Bank

Source of Supply

The High Desert Water Bank with Antelope Valley East Kern Water Agency (AVEK) allows Metropolitan to store supplies to provide additional water for normal and dry year needs. Metropolitan has a storage capability in the groundwater basin, with a capacity of 280 TAF, and a dry year return capability of 70 TAF. The program is planned to be fully operational in 2024.

Expected Supply Capability

The High Desert Water Bank is currently under design and construction. When the High Desert Water Bank is completed, the program would provide 70 TAF of additional water supply capability in a dry year.

Rationale for the Expected Supply

<u>Historical Record</u>

The High Desert Water Bank is expected to be fully operational in 2024. The program may be providing recharge capability earlier. By the end of 2020, the program has yet to store water in its storage account.

<u>Written Contracts or Other Proof</u>

<u>2019 Board Approval of the High Desert Water Bank Agreement.</u> In April 2019, Metropolitan's Board authorized entering into the agreement with AVEK.

Financing

Metropolitan's Board authorized up $131 million for construction of the program with additional funds for program operation.

Federal, State, and Local Permits/Approvals

<u>CEQA Compliance.</u> The Metropolitan Board reviewed and considered AVEK's adopted Mitigated Negative Declaration and took related CEQA action.

J. Bay-Delta Improvements

Source of Supply

Improving the water supply reliability of the State Water Project (SWP) is a primary focus of Metropolitan's long-term planning efforts. Metropolitan's strategy is to reduce its dependence on SWP supplies during dry years, when risks to the Bay-Delta ecosystem are greatest, and to maximize its deliveries of available SWP water during wetter years to store in surface reservoirs and groundwater basins for later use during droughts and emergencies.

State resource agencies and various water user entities are currently engaged in the development of the Delta Conveyance Project (DCP), which would include new diversion and conveyance facilities in the Delta necessary to restore and protect the reliability of SWP water deliveries and, potentially, Central Valley Project (CVP) water deliveries south of the Delta, consistent with the State's Water Resilience Portfolio. The DCP objectives are to address sea level rise, climate change and extreme weather events; minimize the potential for public health and safety impacts from reduced quantity and quality of SWP water deliveries, and potentially CVP water deliveries, south of the Delta resulting from a major earthquake that causes breaching of Delta levees; protect the ability of the SWP, and potentially the CVP, to deliver water when hydrologic conditions result in the availability of sufficient amounts, consistent with the requirements of state and federal law and contractual commitments; and to provide operational flexibility to improve aquatic conditions in the Delta and better manage risks of further regulatory constraints on project operations.

The SWP conveys water from the western slope of the Sierra Nevada to water users both north and south of the Bay-Delta. Specifically, SWP water is delivered to Metropolitan's service area through a system of reservoirs, the Bay-Delta, pumping plants, and the California Aqueduct. Owned and operated by the California Department of Water Resources (DWR), the SWP provides municipal and agricultural water to 29 State Water Contractors. Annual deliveries for the SWP average about 1.96 MAF. Municipal uses account for about 60 percent of annual deliveries, with the remaining 40 percent going to agriculture.

SWP supplies are estimated using the 2019 SWP Delivery Capability Report distributed by DWR in August 2020. The 2019 Delivery Capability Report presents the current DWR estimate of the amount of water deliveries for current (2019) conditions and conditions 20 years in the future. These estimates incorporate regulatory requirements in accordance with the SWRCB Water Quality Control Plan, the USFWS and NMFS biological opinions and the CDFW Incidental Take Permit. In addition, these estimates incorporate 2018 amendments to the Coordinated Operations Agreement between the SWP and CVP. Future capability estimates also reflect the potential impacts of climate change and sea level rise. Under the 2019 Delivery Capability Report, the delivery estimates for the SWP for 2019 conditions as percentage of Table A amounts are seven percent, equivalent to 134 TAF for Metropolitan, under a single dry-year (1977) condition and 58 percent, equivalent to 1.1 MAF for Metropolitan, under long-term average conditions.

In dry, below-normal conditions, Metropolitan has increased the supplies received from the California Aqueduct by developing flexible Central Valley/SWP storage and transfer programs. The goal of these storage/transfer programs is to develop additional dry-year supplies that can be conveyed through the available Banks pumping capacity to maximize deliveries through the California Aqueduct during dry hydrologic conditions and regulatory restrictions.

Delta Conveyance Project

In 2000, several State and federal agencies released the CALFED Bay Delta Programmatic Record of Decision ("ROD") and Environmental Impact Report/Environmental Impact Statement ("EIR/EIS") that outlined and disclosed the environmental impacts of a 30-year plan to improve the Bay-Delta's ecosystem, water supply reliability, water quality, and levee stability. The CALFED ROD remains in effect and many of the State, federal, and local projects begun under CALFED continue.

Building on CALFED and other Bay-Delta planning activities, in 2006 multiple state and federal resource agencies, water agencies, and other stakeholder groups entered into a planning agreement for the Bay-Delta Conservation Plan ("BDCP"). The BDCP was originally conceived as a comprehensive conservation strategy for the Bay-Delta designed to restore and protect ecosystem health, water supply, and water quality within a stable regulatory framework to be implemented over a 50-year time frame with corresponding long-term permit authorizations from fish and wildlife regulatory agencies. The BDCP included both alternatives for new water conveyance infrastructure and extensive habitat restoration in the Bay-Delta.

In 2015, the State and federal lead agencies proposed an alternative implementation strategy and new alternatives to the BDCP to provide for the protection of water supplies conveyed through the Bay-Delta and the restoration of the ecosystem of the Bay-Delta, termed "California WaterFix" and "California EcoRestore," respectively. In this alternative approach, DWR and the

Bureau of Reclamation would implement planned water conveyance improvements as a stand-alone project. Ecosystem improvements and habitat restoration more generally (California EcoRestore) would be undertaken under a more phased approach than previously contemplated by the BDCP and would not be linked with the California WaterFix project or permits. Accelerated restoration actions totaling 30,000 acres of tidal marsh habitat were proposed to be undertaken in the coming decade to provide public benefits for listed fish in the Bay-Delta.

In his State of the State address delivered February 12, 2019, Governor Newsom announced that he did not "support WaterFix as currently configured" but does "support a single tunnel." On April 29, 2019, Governor Newsom issued Executive Order N-10-19, directing several agencies to (among other things), "inventory and assess… [c]urrent planning to modernize conveyance through the Bay Delta with a new single tunnel project." In light of the Governor's announcement and Executive Order, DWR withdrew all approvals and environmental compliance documentation associated with California WaterFix.

On January 15, 2020, DWR issued a Notice of Preparation of Environmental Impact Report for the Delta Conveyance Project. Planning, environmental review and conceptual design work by DWR for a proposed single tunnel project is expected to take approximately 18 to 36 months.

California EcoRestore

The main objective under the EcoRestore Program is to pursue at least 30,000 acres of Delta habitats. These restoration programs would include projects and actions that are in compliance with pre-existing regulatory requirements designed to improve the overall health of the Delta. Other priority restoration projects would also be identified by the Delta Conservancy and other local governments. Funding would be provided through multiple sources including state bonds and other state-mandated funds, SWP/CVP contractors funds as part of existing regulatory obligations, and from various local and federal partners.

As of May 2020, 32 projects have been identified that restore more than the targeted 30,000 acres of habitat, including a projected 18,580 acres of floodplain, 14,000 acres of tidal habitat, 3,500 acres of non-tidal wetlands and 1,650 acres of riparian and upland habitat. To date, 12 projects have been completed, four more are under construction, and the remaining 16 projects are planned to begin construction by 2021.

Sites Reservoir

Sites Reservoir first emerged as part of a second stage of the SWP proposed in the 1980s, which included a peripheral canal and other northern California water-related projects. In 1996, the project was further analyzed by DWR and USBR as part of the CALFED Bay-Delta process. The CALFED process resulted in a Programmatic Record of Decision that recommended implementation of the project as a component of the Preferred Program Alternative. In 2010, the Sites Project Authority was formed as a joint powers authority to continue moving forward with development of the Sites Reservoir project.

Sites Reservoir would be located north of Sacramento, about 10 miles west of the town of Maxwell. The project includes water storage reservoir of 1.3 to 1.5 MAF and would require the construction of two large dams up to 310 feet high and nine smaller saddle dams. The water stored in the reservoir would be diverted from the Sacramento River during high flow events and returned to the Sacramento River during dry and critical years, thereby providing additional dry-year water for environmental flows and project partners including CVP and SWP agencies south of the Delta.

The current operations model estimates the annual water yield of Sites Reservoir at approximately 240 TAF per year. This model utilizes upstream Sacramento River flow and fishery criteria, assumed in earlier phases of the Project. Additional modeling analyses will continue to be conducted as further refinements are made to Project operations and projected regulatory requirements, including proposed Delta Conveyance operations. Implementation of the proposed Delta Conveyance Project would allow for greater yields south of the Delta. DWR estimates that if the Project were operational in 2016 (categorized as a 'below-normal' water year for the Sacramento River), the reservoir could have captured 448 TAF of water supplies. Final Project formulation and annual operations will determine how the firm yield will be divided between meeting water supply and environmental improvements funded by state Proposition 1 grant and federal Water Infrastructure Investment for the Nation (WIIN) Act appropriations.

In 2020, the Sites Project Authority and its participating agencies conducted an internal value-planning effort to minimize potential project costs and impacts. That effort resulted in a project cost reduction of over $2 billion (i.e., $5.2B to $2.9B). The Sites Project Authority is recommending a new workplan and schedule that will move the project forward through the end of 2021. This 16-month workplan (Phase 2) will focus on the continued development and possible revision of project permits and environmental planning documents, and the development of a final feasibility report, and a draft operations plan.

An initial feasibility study and Administrative Draft Environmental Impact Report (EIR) were completed in 2013 by DWR. A Public Draft EIR/Environmental Impact Statement (EIS) for the Project was released by the Sites Project Authority (state lead agency) and the USBR (federal lead agency) in August 2017. However, with the completion of the recent value-planning process, a Revised Draft EIR and Supplemental EIS will need to be released due to the smaller Project footprint and operational changes. The Revised Draft EIR and Supplemental EIS are scheduled to be released in July 2021, with a Final EIR/EIS completed in mid-2022.

Water Quality Control Plan for the Bay-Delta/Voluntary Agreements

The State Water Resources Control Board (SWRCB) is continuing its phased review and update of the 2006 Water Quality Control Plan for the Bay-Delta (Bay-Delta WQCP). Phase 1 focuses on the southern Delta salinity objectives for the protection of agriculture, San Joaquin River flow objectives for the protection of fish and wildlife, and a program of implementation for achieving those objectives. Phase 2 considers the comprehensive review of the other elements of the Bay-Delta WQCP, including but not limited to Sacramento River and Delta outflow objectives.

The SWRCB has also encouraged all stakeholders to work together to reach one or more voluntary agreements for consideration by the SWRCB that could implement the proposed amendments to the Bay-Delta WQCP through a variety of tools, while seeking to protect water supply reliability. Metropolitan is participating in the Phase 2 proceedings and voluntary agreement negotiations.

In December 2018, the SWRCB adopted the Plan amendments and Final Substitute Environmental Document for Phase 1, which establishes the Lower San Joaquin River flow objectives and revised southern Delta salinity objectives. On February 25, 2019, the Office of Administrative Law approved the Plan amendments, which are now in effect, although enforceable obligations to implement the water quality objectives will be imposed in future proceedings involving the specific exercise of the SWRCB's water right or water quality authority. Various stakeholders filed suit against the SWRCB challenging the Phase 1 amendments.

The Phase 1 amendments are highly controversial because they include new requirements for the San Joaquin River tributaries (Stanislaus, Tuolumne, and Merced Rivers) of 40-percent of unimpaired outflow, with an adaptive range between 30-percent and 50-percent for the protection of fish and wildlife beneficial uses. Unimpaired flow is the flow that would accumulate in surface waters in response to rainfall and snowmelt and flow downstream if there were no reservoirs or diversions to change the quantity, timing, and magnitude of flows. Modeling of this objective shows significant reductions in water supplies available for human consumptive use during most water year types. While the southern Delta salinity objective for the protection of agricultural beneficial uses has been amended to 1.0 dS/m EC (a measure of salinity), the Phase 1 amendments continue the United States Bureau of Reclamation's existing obligation to meet 0.7 dS/m EC on the Lower San Joaquin River at Vernalis.

As part of Phase 2 proceedings, the SWRCB released a framework document in July 2018 focused on the Sacramento River and its tributaries, Delta eastside tributaries, Delta interior Delta flows and Delta outflows. The framework describes changes that will likely be proposed by SWRCB staff through formal proposed amendments and supporting environmental documents. The proposed changes include certain unimpaired flow requirements for the Sacramento River and its salmon-bearing tributaries. an inflow level of 45-percent to 65-percent of unimpaired flow, with a starting point of 55-percent.

The SWRCB has also encouraged all stakeholders to work together to reach one or more voluntary agreements for consideration by the SWRCB that could implement the proposed amendments to the Bay-Delta WQCP through a variety of tools, while seeking to protect water supply reliability. In July of 2019, the State submitted to the SWRCB an update on the voluntary agreement processes. On February 4, 2020, the State agencies released a framework for voluntary agreements that outlined a 15-year program to improve environmental conditions, in an adaptive way, through new flows dedicated to the environment and providing additional habitat. The California Natural Resources Agency and the California Environmental Protection Agency are leading an effort to negotiate voluntary agreements to improve conditions for native fish through an unprecedented commitment to increased flows for the environment, creation of 60,000 acres of new and restored habitat, and $5 billion in new funding for environmental improvements and science. If successful, these agreements will implement the SWRCB's legally required update to the Bay-Delta WQCP and improve conditions for native fish through a broad set of tools. The agreements hold the potential to achieve meaningful landscape-scale solutions to meet the needs of the Delta and its major rivers, reconnect our floodplains and wetlands to the rivers and estuary, and comprehensively manage these vital watersheds. Metropolitan is participating in the Phase 2 proceedings and voluntary agreement discussions.

Rationale for the Expected Supply

Implementation Status

Expected supplies are projected in accordance with the approved implementation.

Written Contracts or Other Proof

Metropolitan Board Actions and Policies:

Policy Principles Regarding Long-term Actions for the Sacramento-San Joaquin River Delta approved in April 2006.

Delta Action Plan Framework approved in June 2007.

Delta Conveyance Criteria approved in September 2007.

Execution of Initial Funding Agreement approved in December 2008.

Execution of Amendments to Planning Agreement approved in December 2009.

Execution of Planning Agreement Amendment (additional funds) approved in July 2010.

Execution of Amendment to Memorandum of Agreement approved in August 2011.

Authorized Funding and Entered into Project Agreement with Sites Project Authority for Phase 1, April 2017.

Authorized Funding and Entered into Project Agreement with Sites Project Authority for 2019 Workplan, February 2019.

Appropriated Funding and Authorized Amendment to 2019 Reservoir Project Agreement with Sites Project Authority to Allow Participation in Phase 2 Workplan, November 2020.

Board action on "Water Management Tools" approved February 2021.

Board vote on California WaterFix, October 2017.

Board vote on California WaterFix, July 2018.

Board vote on Funding Agreement with DWR for Metropolitan's share of the Delta Conveyance Project planning and pre-construction costs, and execution of an amendment to the Joint Powers Agreement for Delta Conveyance Design and Construction Authority, December 2020.

Supporting Agreements and Contracts:

Bay-Delta Accord approved in December 1994.

CALFED Framework, June 2000.

Lower Yuba River Accord, May 2008.

Delta Reform Act Legislation enacted in 2009.

State and Federal Funding:

Proposition 204 funds approved by voters in November 1996.

Proposition 13 funds approved by voters in March 2000.

Proposition 50 funds approved by voters in November 2002.

Proposition 1, approved by the voters in 2014, authorized $7.545 billion in general obligation bonds for state water supply infrastructure projects, including surface and groundwater storage, ecosystem and watershed protection and restoration, and drinking water protection.

Annual federal appropriations from 1998 to present, authorized in annual Energy and Water Development Appropriations balls and the CALFED Bay-Delta Authorization Act.

California Water Commission approved $816 million of Proposition 1 funding for Sites Reservoir, July 2018

Financing

The Delta Conveyance Project would be paid for by public water agencies that would receive the water supply reliability benefits.

California EcoRestore is a program separate from the Delta Conveyance Project and the prior California WaterFix planning efforts. The state would pursue at least 30,000 acres of Delta habitat restoration over the next few years, pursuant to pre-existing regulatory requirements such as the 2008 and 2009 Biological Opinions and various enhancements to improve the overall health of the Delta ecosystem and its native fish and wildlife species. Proposition 1 funds and other state public dollars will be directed exclusively for public benefits unassociated with any regulatory compliance responsibilities.

Federal, State, and Local Permits/Approvals

CALFED's Bay-Delta Program.

CALFED Programmatic EIR/EIS finalized in July 2000.

Record of Decision issued in August 2000 for the final Programmatic EIR/EIS regarding the CALFED Bay-Delta Program.

K. Kern Delta Water Management Program

Source of Supply

In December 1999, Metropolitan advertised a request for proposals for participation in "The California Aqueduct Dry-year Transfer Program." As a result of this request for proposals, four programs, including one from the Kern Delta Water District (Kern Delta), were selected for further consideration. In 2001, Metropolitan entered into Principles of Agreement with Kern Delta for the development of a dry-year supply program. Kern Delta serves 125,000 acres of actively farmed highly productive farmland located in the San Joaquin Valley portion of southern Kern County. Kern Delta has under contract 180 TAF per year of good quality, highly reliable pre-1914 Kern River water and 25.5 TAF per year of SWP Table A contract right (under contract with Kern County Water Agency).

The dry-year supply program between Kern Delta and Metropolitan involves the storage of water with Kern Delta. In years of plentiful supply, the agreement allows Metropolitan to store water in Kern Delta's groundwater basin, either through direct spreading operations or through deliveries to growers in Kern Delta's service area. Metropolitan has the ability to store up to 250 TAF of water. Agreement provisions may allow for storage beyond this amount. When needed, Metropolitan can recover its stored water either through direct pumping of the groundwater or exchange at a rate of 50 TAF per year. The program duration will be from 2002 to 2027 with provisions that allow the water to be withdrawn until 2033.

Expected Supply Capability

The Kern Delta/Metropolitan Program provides Metropolitan with the capacity to store up to 250 TAF of water at any one time. When needed, Metropolitan can recover its stored water either through direct pumping of the groundwater or exchange at a rate of 50 TAF per year.

Rationale for the Expected Supply

Implementation Status

Expected supplies are projected in accordance with accepted detailed groundwater modeling that has been accomplished for the program. In addition, the Kern Delta/Metropolitan Water Management Program was operational and accepting water for storage by fall of 2003. By the end of 2020, the program had 181 TAF in its storage account.

Written Contracts or Other Proof

2001 Kern Delta/Metropolitan Principles of Agreement. Principles of agreement were entered into between Kern Delta and Metropolitan in June 2001, covering program costs, operational aspects, and risks/responsibilities.

2002 Kern Delta and Metropolitan Boards of Directors Approval. These actions approved execution of the long-term agreement, which delineates program operations, costs, and risks/responsibilities

Financing

Metropolitan's O&M budget (referenced above) includes payments for the Kern Delta/ Metropolitan Program.

Federal, State, and Local Permits/Approvals

Kern Delta, acting as lead agency under CEQA, has prepared a full EIR. As part of this EIR, Kern Delta published a Notice of Preparation and held meetings with the general public, interested agencies, and resource agencies. In November 2002, the Final EIR was certified by Kern Delta and adopted by Metropolitan.

L. Central Valley / State Water Project Storage and Water Transfers

Source of Supply

Around 34 MAF of water (80 percent of California's developed water) is delivered for agricultural use every year. Over half of this water is used in the Central Valley; and much of it is delivered by, or adjacent to, SWP and Central Valley Project (CVP) conveyance facilities. This allows for the voluntary transfer of water to many urban areas, including Metropolitan's service area, via the California Aqueduct.

In recent years, a portion of this agricultural water supply has been secured by Metropolitan through mutually beneficial transfer agreements:

The Governor's Water Bank (Bank) in 1991, 1992, 1994, and 2009 secured 75 to 820 TAF per year of water supply. Further, the DWR's Dry Year Water Purchase Program (Purchase Program) in 2001, 2002, and 2003 secured a total of 162 TAF. DWR established and administered the Bank and the Purchase Program by facilitating purchasing water from willing sellers and transferring the water to those with critical needs using the SWP facilities. Sellers, such as farmers and water districts, made water available for the Bank and Purchase Program by fallowing crops, shifting crops, releasing surplus reservoir storage, and by substituting groundwater for surface supplies.

In 2003, Metropolitan secured options to purchase approximately 145 TAF of water from willing sellers in the Sacramento Valley during the irrigation season. Using these options, Metropolitan purchased approximately 125 TAF of water for delivery to the California Aqueduct.

In 2005, Metropolitan, in partnership with three other SWC, secured options to purchase approximately 130 TAF of water from willing sellers in the Sacramento Valley during the irrigation season, of which Metropolitan's share was 113 TAF. Metropolitan also had the right to assume the other SWC options if they chose not to exercise their options. Due to improved hydrologic conditions, Metropolitan and the other SWC did not exercise these options.

In December 2007, Metropolitan entered into a long-term agreement with DWR providing for Metropolitan's participation in the Yuba Dry Year Water Purchase Program between Yuba County Water Agency and DWR that was approved by the SWRCB as part of the Yuba River Accord. This program provides for transfers of water from the Yuba County Water Agency during dry years through the year 2025, and Metropolitan has purchased approximately 200 TAF to date.

In 2008, Metropolitan, in partnership with eight other SWC, purchased approximately 40 TAF of water from willing sellers in the Sacramento Valley during the irrigation season, of which Metropolitan's share was approximately 27 TAF.

In 2009, Metropolitan participated in the Governor's Water Bank, which purchased approximately 74 TAF, of which Metropolitan's share was approximately 36.9 TAF.

In 2010, Metropolitan in partnership with three other SWC, secured approximately 100 TAF of water from willing sellers in the Sacramento Valley, of which Metropolitan's share was approximately 88 TAF.

In 2010, Metropolitan purchased approximately 18 TAF of water from CVP Contractors located in the San Joaquin Valley. In addition, Metropolitan entered into an unbalanced exchange agreement that resulted in Metropolitan receiving approximately 37 TAF.

In 2015, Metropolitan, in partnership with eight other SWC, secured approximately 20 TAF of water from willing sellers in the Sacramento Valley, of which Metropolitan's share was approximately 12 TAF.

In addition, Metropolitan has secured water transfer supplies under the Multi-Year Water Pool Demonstration Program. In 2013, 2015, and 2016, Metropolitan secured 30 TAF, 1.3 TAF, and 7 TAF, respectively. Unlike the other transfer programs discussed herein, which were derived from agricultural sellers, a portion of these transfer supplies came from urban sellers.

Expected Supply Capability

The combined effect of the 2019 National Marine Fisheries Service's and United States Fish and Wildlife Service's biological opinions and the 2020 California Department of Fish and Wildlife's Incidental Take Permit have resulted in uncertainty in how the CVP and SWP will be operated to facilitate water transfers. The new state and federal permits result in the SWP being required to dedicate approximately 200 TAF on average to additional outflow, in addition to the SWP being required to reduce water diversions under a larger number of environmental conditions. The CVP is not subject to the same state permit requirements and will be diverting more frequently, particularly in April and May. There are also new limits on the CVP's ability to use the SWP's facilities for water transfers, particularly when the SWP is under heightened export limits, which could impact how water transfer deals are structured. While the new state and federal permits allow the water transfer window to be extended through November, the 2020 state Incidental Take Permit includes new November export limits on the SWP; and when these limits are triggered, the CVP would also be precluded from using SWP facilities. Under the new permit, the SWP is further obligated to implement a new water transfer monitoring program, which will increase costs to the SWP water contractors.

Rationale for the Expected Supply

<u>Historical Record</u>

Metropolitan has made rapid progress in developing SWP transfer programs. This progress may be attributed to several factors, including Metropolitan dedicating additional staff to identify, develop, and implement SWP transfer programs; increased willingness of Central Valley agricultural interests to enter into transfer programs with Metropolitan; and Metropolitan staff's ability to work with DWR and USBR staff to facilitate SWP storage and transfer programs. The availability of dry year supplies has been demonstrated by the annual water purchase programs described above. In addition, Metropolitan participates in longer-term programs to secure water like the Yuba Accord and the Multi-Year Water Pool Demonstration Program.

The historical record for purchases from the Bank, Purchase Program, Metropolitan-initiated Central Valley programs, Yuba Accord, and Multi-Year Demonstration Program, as well as the number of sellers and buyers participating in these Programs, are strong indicators that there are significant amounts of water that can be purchased through spot market or long-term water transfers during dry years. This historical record from 1991 through 2016 is summarized in Table A.3-1 below. Metropolitan did not purchase supplies from nor participated in any dry year transfer programs from 2017 through 2020.

Approximately 20-35 percent of these north of the Delta water transfers are dedicated to improving Delta water quality to comply with regulations governing Delta pumping.

<u>Written Contracts or Other Proof</u>

With near record-low precipitation in California in recent years, Governor Edmund G. Brown Jr. issued several executive orders to expedite processing of water transfers within the state:

Executive Order B-21-13 (May 20, 2013): The Department of Water Resources and the State Water Resources Control Board are to "take immediate action to address the dry conditions and water delivery limitations by doing the following: … (1) Expedite processing of one-year water transfers for 2013 and assist water transfer proponents and suppliers as necessary, provided that the transfers will not harm other legal users of water and will not unreasonably affect fish, wildlife, or other in-stream beneficial uses; (2) The SWRCB shall expedite review and processing of water transfer petitions in accordance with the applicable provisions of the Water Code; (3) The DWR shall expedite and facilitate water transfer proposals in accordance with applicable provisions of the Water Code..."

January 1, 2014 Drought Proclamation: "The Department of Water Resources and the State Water Resources Control Board will expedite the processing of water transfers, as called for in Executive Order B-21-13. Voluntary water transfers from one water right holder to another enables water to flow where it is needed most."

April 25, 2014 Drought Proclamation: "The Department of Water Resources and the State Water Resources Control Board will immediately and expeditiously process requests to move water to areas of need, including requests involving voluntary water transfers, forbearance agreements, water exchanges, or other means. If necessary, the Department will request that the Water Board consider changes to water right permits to enable such voluntary movements of water."

Executive Order B-29-15 (April 1, 2015): "The Department shall immediately consider voluntary crop idling water transfer and water exchange proposals of one year or less in duration that are initiated by local public agencies and approved in 2015 by the Department subject to the criteria set forth in Water Code section 1810." [This executive order incorporated by reference the previous drought proclamations.]

In February 2021, Metropolitan's Board approved a water management amendment to the State Water Contract that provides greater water management flexibility with transfers and exchanges of SWP water within the SWP service area. The amendment will provide increased opportunities among the State Water Project Contractors to work together on programs that will improve the management of existing SWP water.

Table A.3-1
Historical Record of MWD Central Valley Water Transfers

Program	Purchases (AF per year) Total	Metropolitan	Participants Sellers	Buyers
1991 Governor's Water Bank	820,000	215,000	351	13
1992 Governor's Water Bank	193,246	10,000	18	16
1994 Governor's Water Bank	220,000	100	6	15
2001 Dry-Year Purchase Program	138,806	80,000	9	8
2003 MWD Water Transfer Program	146,230[1]	126,230	11	1
2005 SWC Water Transfer Program	127,275[2]	0	3	4
2008 SWC Water Transfer Program	39,152	26,621	4	8
2009 Governor's Water Bank	47,505	36,900	10	9
2010 SWC Water Transfer Program	98,959	88,159	11	4
2013 Multi-Year Water Pool Demo	92,232	30,000	4	9
2015 Multi-Year Water Pool Demo	3,000	1,374	1	14
2015 SWC Water Transfer Program	19,686	12,358	5	9
2016 Multi-Year Water Program	15,000	6,871	2	9

[1] Quantities denote options Metropolitan secured, of which 20,000 AF were not exercised due to improved hydrologic conditions.

[2] Quantities denote options Metropolitan secured, but were not exercised due to improved hydrologic conditions.

Agreements Between Sellers and Buyers. Since 1991, Metropolitan has entered into Central Valley water transfer agreements in eleven years with sellers, or DWR acting in an intermediary capacity for the Drought Water Bank. The essential terms and conditions for negotiating purchases, including maximum offering price, quantity of water needed, and the timing of delivery, were established in these agreements.

1999 Board Directive. Metropolitan's Board has authorized water transfers in accordance with the Water Surplus and Drought Management Plan (WSDM Plan) adopted in April 1999. The WSDM Plan is a comprehensive policy guideline for managing Metropolitan's water supply during periodic surplus and shortage conditions. During shortage conditions, the plan specifies the type, priority, and timing of drought actions, including the purchase of transfers on the spot market that could be taken in order to prevent or mitigate negative impacts on retail demands.

Financing

Funds for Central Valley water transfers are included in Metropolitan's O&M budget (referenced above).

Federal, State, and Local Permits/Approvals

Environmental documentation for the Drought Water Bank. In November 1993, DWR prepared and finalized a programmatic EIR for the operation of the Drought Water Bank during future drought events. In 2009, an emergency CEQA exemption was issued to support the Drought Water Bank.

Individual CEQA and NEPA documents for Metropolitan's 2003, 2005, and 2008 Central Valley water transfer programs. Individual sellers prepared CEQA documentation to support their transfers. In addition, the USBR prepared NEPA documentation for those transfers requiring federal approval.

M. Mojave Storage Program

Source of Supply

Water from Metropolitan's SWP supply is delivered to Mojave Water Agency through SWP facilities for deposit into an exchange account managed by Mojave. Returns to Metropolitan are made on an acre-foot-for-acre-foot basis (i.e., no losses) at Metropolitan's request by exchange with Mojave's SWP supplies delivered through SWP facilities, subject to rules reserving a minimum annual SWP supply for use by Mojave.

Expected Supply Capability

Through 2021, Metropolitan can annually withdraw the Mojave Water Agency's SWP contractual amounts in excess of 10%. After 2021, the withdrawal rate lowers, reserving 20% of Mojave Water Agency's SWP contractual amounts. Under a 100% allocation, the State Water Contract provides Mojave Water Agency 82.8 TAF of water.

Rationale for the Expected Supply

Implementation Status

Presently, the Mojave Water Agency is not accepting additional water from Metropolitan. As of January 2021, Metropolitan has approximately 19 TAF remaining in storage. Without additional deliveries to the exchange account, the program may not be able to provide return supplies beyond 2025.

Written Contracts or Other Proof

2003 Mojave Water Agency and Metropolitan Boards of Directors Approval. These actions approved the Mojave Water Agency Groundwater Recharge and Exchange Demonstration Project.

2003 Agreement for a Demonstration Water Exchange Program. Provided for a demonstration water exchange between Metropolitan and the Mojave Water Agency for the immediate benefit of both agencies and for the purpose of determining what mutual benefits can result from increased coordinated management of water and facilities. Provides for Metropolitan to deliver up to 75,000 AF for an exchange through December 2004 and the return of water to Metropolitan by December 2014.

2005 Mojave Water Agency and Metropolitan Boards of Directors Approval. These actions approved a one-year extension of the period for Metropolitan to deliver up to the maximum amount of 75,000 AF for an exchange and a one-year extension of the return of water supply to Metropolitan.

2005 First Amendment to the Agreement for a Demonstration Water Exchange Program. Provides for a one-year extension of the period for Metropolitan to deliver up to the maximum amount of 75,000 AF for an exchange and a one-year extension of the return of water supply to Metropolitan.

2011 Mojave Water Agency and Metropolitan Boards of Directors Approval. These actions approved an amendment to the Agreement for a Demonstration Water Exchange Program to provide for a longer term Water Storage Program for Metropolitan to store up to an additional 390,000 acre-feet of SWP supplies through 2035.

2011 Amended Agreement for a Water Storage Program. Establishes the Water Storage Program under which Metropolitan to store up to an additional 390,000 acre-feet of SWP supplies through 2035 for subsequent return by Mojave Water Agency.

Financing

Metropolitan O&M budget includes payments to deliver Metropolitan's SWP supplies to Mojave Water Agency and the recovery on that water by exchange with Mojave Water Agency's SWP supplies.

Federal, State, and Local Permits/Approvals

The Mojave Water Agency, as the Lead Agency, adopted a Final Environmental Impact Report on January 26, 2006, for the Mojave Water Agency Water Supply Reliability and Groundwater Replenishment Program (SCH#2005041103), adopted a mitigation monitoring and reporting program, and filed a Notice of Determination with the State Clearinghouse on January 31, 2006. Metropolitan's Board certified the CEQA documents as a Responsible Agency on July 12, 2011.

On September 8, 2011, Metropolitan and Mojave Water Agency entered into a Point of Delivery Agreement with DWR providing for the delivery of Metropolitan's SWP supplies to Mojave Water Agency and the return to Metropolitan through an exchange of Mojave's SWP supplies.

N. Yuba Accord Dry Year Purchase Program

Source of Supply

As part of a comprehensive settlement of a State Water Resources Control Board (SWRCB) proceeding in which the Yuba County Water Agency (YCWA) is required to increase Yuba River fishery flows, referred to as the "Yuba River Accord" (Accord), YCWA reached agreement with DWR and USBR to sell a portion of the water it would be required to release, plus additional water made available by reoperation of YCWA's storage reservoirs and groundwater substitution. DWR entered into a purchase agreement with YCWA under which one-half of the water available for purchase would be available to SWP contractors that elected to participate in the purchase program.

Under this 25-year program, the price for water is set by the agreement between DWR and the YCWA. There are four categories of water sold, and the price for each type of water depends on hydrology.

Expected Supply Capability

Metropolitan's share of the water made available under the Yuba Accord Dry Year Purchase Program is approximately 25 percent. Should other participating contractors decline to purchase their respective shares, that water is allocated to the remaining interested participating contractors. Metropolitan's likely share of assured YCWA transfer water would be at least 13,750 AF in dry years and up to 35,000 AF or more in other years. These volumes are as provided by YCWA north-of-the-Delta and are subject to conveyance losses through the Delta to the Banks Pumping Plant (approximately 20 to 35 percent).

Rationale for the Expected Supply

Historical Record

Actual volumes purchased by Metropolitan since program inception were as follows:

Year	**Purchased Volume (AF)**
2008	26,430
2009	42,915
2010	67,068
2011	0
2012	0
2013	14,548
2014	10,962
2015	8,192
2016	0
2017	0
2018	21,131
2019	0
2020	8,950 Estimate

Written Contracts or Other Proof

DWR-YCWA Purchase Agreement. This December 4, 2007, agreement provides the annual determination of the amount of water to be made available by YCWA and purchased by DWR. The agreement also specifies the costs of various categories of water to be made available under a variety of hydrologic conditions.

DWR-Metropolitan Participation Agreement. This December 21, 2007, agreement provides Metropolitan's election to purchase water made available by YCWA to DWR and the scheduling delivery of the purchased water. The agreement provides for mechanisms for Metropolitan payments to DWR that are due to YCWA under the DWR-YCWA Purchase Agreement.

Amended DWR-Metropolitan Participation Agreement. This December 5, 2014, amendment established prices for surface water transfer supplies between 2016 and 2020 and clarifies YCWA's rights to sell to third parties.

Amended DWR-Metropolitan Participation Agreement. The amendment, executed in September 2020, established new prices for surface water transfer supplies between 2020 and 2025.

Financing

Funds for purchases of water from the Yuba Accord Dry Year Purchase Program are included in Metropolitan's O&M budget (referenced above).

Federal, State, and Local Permits/Approvals

SWRCB Order WR 2008-0014. Approval of YCWA's petition to modify revised Water Right Decision 1644 related to Water Right Permits 15026, 15027, and 15030 (Applications 5632, 15204, and 15574), and petition for long-term transfer of up to 200,000 AF of water per year from YCWA to the DWR and the USBR under Permit 15026 (Application 5632) - Lower Yuba River in Yuba County.

O. 2011 Coordinated Operating, Water Storage, Exchange and Delivery Agreement among Metropolitan, Municipal Water District of Orange County, and Irvine Ranch Water District

Source of Supply

In July 2010, Metropolitan's Board authorized the Coordinated Operating, Water Storage, Exchange and Delivery Agreement among Metropolitan, Municipal Water District of Orange County (MWDOC), and Irvine Ranch Water District (IRWD). The agreement allows Metropolitan to manage additional SWP supplies obtained from other State Water Contractors. The SWP supplies are obtained through unbalanced exchanges with other State Water Contractors and stored in IRWD storage facilities along the California Aqueduct. Metropolitan maintains ownership and control over the SWP supplies that would be later delivered into the region. MWDOC and IRWD receive a benefit that when the storage programs operate consistent with Metropolitan's Water Supply Allocation Plan, MWDOC and IRWD would receive an extraordinary supply benefit. MWDOC continues to pay the full-service rate for the water generated and delivered under the program.

Expected Supply Capability

The average annual supply benefit is estimated at around 2,000 AFY which can vary drastically based on hydrologic conditions. The maximum supply benefit during a water supply allocation may be as high as 28,750 AF if IRWD has sufficiently developed supplies in storage.

Rationale for the Expected Supply

The expected supply is estimated on the SWP Supplies that the program typically develops through 2020.

Historical Record

The program has allowed Metropolitan to acquire additional supplies through unbalanced exchanges with Antelope Valley-East Kern Water Agency, Dudley Ridge Water District, and Santa Barbara County Flood Control and Water Conservation District.

Written Contracts or Other Proof

2011 Coordinated Operating, Water Storage, Exchange and Delivery Agreement among Metropolitan, Municipal Water District of Orange County, and Irvine Ranch Water District.

Financing

Metropolitan does not fund the exchanges or storage program. IRWD is responsible for the normal program costs. There are provisions where Metropolitan can utilize the program facilities on a limited basis and would reimburse actual operating costs.

A.3.3 In-Region Storage and Supplies

A. Surface Storage

Source of Supply

Surface storage is a critical element of Southern California's water resources strategy. Because California experiences dramatic swings in weather and hydrology, surface storage is important to regulate those swings and mitigate possible supply shortages. Surface storage provides a means of storing water during normal and wet years for later use during dry years, when imported supplies are limited. Since the early twentieth century, DWR and Metropolitan have constructed surface water reservoirs to meet emergency, drought/seasonal, and regulatory water needs for Southern California. These reservoirs include Pyramid Lake, Castaic Lake, Elderberry Forebay, Silverwood Lake, Lake Perris, Lake Skinner, Lake Mathews, Live Oak Reservoir, Garvey Reservoir, Palos Verdes Reservoir, Orange County Reservoir, and Metropolitan's DVL. Some reservoirs such as Live Oak Reservoir, Garvey Reservoir, Palos Verdes Reservoir, and Orange County Reservoir, which have a total combined capacity of about 3,500 AF, are used solely for regulating purposes. The remaining surface reservoirs are primarily used to meet emergency, drought, and seasonal requirements. The total gross storage capacity for these larger remaining reservoirs is 1,757,600 AF. However, not all of the gross storage capacity is available to Metropolitan; dead storage and storage allocated to others reduce the amount of storage that is available to Metropolitan to 1,665,200 AF.

Expected Supply Capability

Surface storage reservoirs are an important tool that allows Metropolitan to meet the water needs of its service area. As discussed in the EIR for the Eastside Reservoir (DVL) Project dated October 1991 and Metropolitan's IRP, the allocation of available surface storage can be divided into two primary components: emergency and drought/seasonal. As specified by Metropolitan's Board of Directors in the Final EIR for DVL, "Metropolitan shall maintain sufficient water reserves within its service area to supplement local production during an emergency or severe water shortage." With DVL in operation, Metropolitan can now re-operate the surface reservoirs and meet the Board's stated objectives.

Updated Emergency Storage Objective

Metropolitan established its original criteria for determining emergency storage requirements in the October 1991 Final Environmental Impact Report for the Eastside Reservoir, which is now named Diamond Valley Lake. These criteria were again discussed in the 1996 IRP. Metropolitan's Board approved both of these documents. Emergency storage requirements are based on the potential of a major earthquake that would damage all supply aqueducts isolating Southern California from its imported water sources. In 2019, Metropolitan and its member agencies completed a process to update the regional planning estimate of Metropolitan's Emergency Storage Objective. This emergency storage represents the amount of water that Metropolitan would store for the region in preparation for a catastrophic earthquake that would damage the aqueducts that transport imported water supplies to Southern California, including: the Colorado River Aqueduct, both the East and West branches of the California Aqueduct, and the Los Angeles Aqueduct. The emergency storage allows Metropolitan to deliver reserve supplies to the member agencies to supplement local production. This helps avoid severe water shortages during periods when the imported water aqueducts may be out of service. The Emergency Storage Objective considers a six- and twelve-month outage period for the imported supply aqueducts incorporating latest seismic information and operational flexibility of Metropolitan's system, a retail water demand cutback ranging from 25 to 35 percent considering the level of conservation that the region achieved during the recent drought, and an aggregated loss of 10 to 20 percent of local supplies accounting for factors could affect local production during emergency conditions. Under this update, Metropolitan's Emergency Storage Objective was set to 750 TAF, as this level of storage would prevent severe water shortages to the region given new information on expected recovery durations. The emergency storage volume represents a planning estimate for the amount of water that Metropolitan would store for the region in preparation for a catastrophic earthquake or other disaster. It is not intended to set a basis or a policy for allocating or apportioning storage for any individual member agency. A detailed description of Metropolitan's Emergency Storage Objective is included in Appendix 8.

The storage reserved in system reservoirs for emergency purposes is shown in Table A.3-2.

Updated Storage Requirements for Dry-Year Supply and Seasonal Needs

Storage capacity in system reservoirs, including DVL, is also earmarked for dry-year supply and system regulation purposes. Dry-year supply storage within Metropolitan's service area is required to meet the additional water demands that occur during single-year and extended droughts. As specified in the Final EIR for DVL and further discussed in the IRP, this storage requirement is defined as the difference between average-year demand and above average demand during dry years. In addition to dry-year storage, seasonal storage is required to meet seasonal peak demands, which are defined as the difference between average winter demands and average summer demands. The dry-year supply and seasonal storage also provide sufficient reserves to permit approximately five percent downtime for rehabilitation, repair, and maintenance of raw water transmission facilities.

Table A.3-2
Surface Storage Utilization
(acre-feet per year)

Forecast Year	2025	2030	2035	2040	2045
MWD Dry-Year/Seasonal Surface Storage					
DVL, Mathews, Skinner	596,000	596,000	596,000	596,000	596,000
Flexible Storage in Castaic & Perris	217,000	217,000	217,000	217,000	216,000
Subtotal of Dry-Year/Seasonal Storage	**813,000**	**813,000**	**813,000**	**813,000**	**812,000**
MWD Emergency Storage					
DVL, Mathews, Skinner	436,000	436,000	436,000	436,000	436,000
Emergency Storage in DWR Reservoirs	381,000	381,000	381,000	381,000	381,000
Subtotal of Emergency Storage	**817,000**	**817,000**	**817,000**	**817,000**	**817,000**
Total MWD Surface Storage	**1,630,000**	**1,630,000**	**1,630,000**	**1,630,000**	**1,629,000**

Historical Record

Metropolitan has a contract with the DWR that allows use of its terminal reservoirs, such as Castaic Lake on the West Branch and Lake Perris on the East Branch of the California Aqueduct (see Section A.3.3.B for a discussion of Metropolitan's contractual rights to storage in these DWR reservoirs). In addition, Metropolitan owns and operates surface reservoirs such as Lake Skinner, Lake Mathews, and DVL to enhance water supply reliability for its member agencies.

Written Contracts or Other Proof of Usage

The surface reservoirs used by Metropolitan are available either by contract (in the case of the DWR terminal reservoirs) or by construction of its own facilities. The following historical record is provided:

November 1960 Contract between the State of California Department of Water Resources and the Metropolitan Water District of Southern California for a Water Supply. This Contract and its numerous amendments describe Metropolitan's legal access to and obligations for the operation of the SWP for the benefit of its Contractors. Metropolitan has an entitlement to 1,911,500 AF of water each year subject to availability. The terms of this Contract describe Metropolitan's rights to and obligations for the terminal surface reservoirs for water supply purposes.

November 1974 Memorandum of Understanding and Agreement on Operation of Lake Skinner. This MOU and the January 2005 Amendment, signed by Metropolitan and other affected parties, govern Metropolitan's operations of Lake Skinner in Riverside County. The DWR Division of Safety and Dams also reviews monitoring data on the safety of the dam annually.

November 1994 Memorandum of Understanding on Operation of Domenigoni Valley Reservoir (now known as Diamond Valley Lake). This MOU, signed by Metropolitan and other affected parties, governs Metropolitan's operations of DVL in Riverside County. The DWR Division of Safety and Dams also reviews monitoring data on the safety of the dam annually.

Elderberry Forebay Contract for Conditions for Use. Conditions for use of storage are described in the contract between the DWR, State of California, and the Department of Water and Power, City of Los Angeles, for Cooperative Development, West Branch, California Aqueduct; Amendment No. 1, July 3, 1969; and Amendment No. 4, June 27, 1985.

June 2002 Division of Safety of Dams Certificate of Approval. The DWR, Division of Safety of Dams issued the Certificate of Approval for operation of DVL in early 2000, with three conditions. These conditions were: (1) Satisfactory operation of the butterfly valves and emergency gate in the inlet/outlet tower, (2) completion of the Tank Saddle Cutoff remediation, and (3) completion of the Signal Spillway. Metropolitan completed these conditions in 2001, and DVL is currently operational in accordance with the Certificate of Approval.

October 1991 Final EIR for the Eastside Reservoir Project (DVL). The EIR established criteria for integrating the operations of Metropolitan's reservoirs and DWR's southern reservoirs for emergency purposes. These criteria also provided that Metropolitan reservoirs could be expected to withdraw all drought storage water within a two-year period.

B. Flexible Storage Use of Castaic Lake and Lake Perris

Source of Storage

Metropolitan's flexible storage accounts in Castaic Lake and Lake Perris, which are SWP reservoirs, are 153,940 AF and 65,000 AF, respectively. These accounts provide Metropolitan with dry-year supply that is independent of the Table A allocation. Metropolitan can withdraw water from these reservoirs in addition to its allocated supply in any year on an as-needed basis. Withdrawn water must be replaced from supplies available to Metropolitan within five years of each withdrawal. This "flexible storage" is available in Castaic Lake to Metropolitan, Ventura County Flood Control and Water Conservation District, and to Santa Clarita Valley Water Agency. It is available in Lake Perris to Metropolitan only.

Expected Supply Capability

The dry-year supply available to Metropolitan from the flexible storage use of Castaic Lake and Lake Perris totals 218,940 AF, made up of 153,940 AF in Castaic Lake and 65,000 AF in Lake Perris. Table A.3-3 shows the use of this available supply in accordance with Metropolitan's operating criteria.

Table A.3-3
Estimated Water Supplies Available for Metropolitan's Use Under the Flexible Storage Use of Castaic Lake and Lake Perris[1]
(TAF per year)

Year	Five Year Drought (1988-1992)	Single Dry Year (1997)
2025	43	217
2030	43	217
2035	43	217
2040	43	217
2045	43	217

[1]Source: Metropolitan's operating criteria.

Rationale for the Expected Supply

Implementation Status

Express provisions related to flexible storage have been incorporated in Metropolitan's SWP contract since 1995. The operating options have been available for use since that time and will continue to be in effect as a part of the SWP contracts.

Historical Record

Metropolitan has exercised the flexible storage provision on numerous occasions and withdrew the full contract amount during calendar year 2014. The full amount was replaced by the beginning of 2017. Its use is based on existing contract provisions.

DWR Bulletin 132-94. The use of Castaic Lake and Lake Perris is determined in accordance with the proportionate use factors from Bulletin 132-94, Table B, upon which capital cost repayment obligations are based. Based on its capital repayment obligations, Metropolitan's proportionate use of Castaic Lake is 96.2 percent and of Lake Perris is 100 percent. Per its SWP contract, Metropolitan has express rights to use certain portions of the SWP's southern reservoirs independently of DWR to supply water in amounts in addition to approved SWP deliveries.

Metropolitan's SWP Contract. Metropolitan's SWP contract was amended in 1995 to include Article 54, "Usage of Lakes Castaic and Perris." This article provides flexible storage to contractors participating in repayment of the capital costs of Castaic Lake and Lake Perris. Each contractor shall be permitted to withdraw up to a Maximum Allocation from Castaic Lake and Lake Perris. These contractors may withdraw a collective Maximum Allocation up to 160 TAF in Castaic Lake and 65 TAF in Lake Perris, which shall be apportioned among them pursuant to the respective proportionate use factors, as shown in Table A.3-4 below.

Financing

The cost associated with the withdrawal and replacement of water in the flexible storage is included in Metropolitan's annual payments under the State Water Contract.

Federal, State, and Local Permits/Approvals

The flexible storage provision became effective in 1995. DWR has the approval authority to affect changes in the operations and usage of existing SWP facilities, including Castaic Lake and Lake Perris.

Table A.3-4
Flexible Storage Allocations

Participating Contractor	Proportionate Use Factor	Maximum Flexible Storage Allocation (AF)
Castaic Lake		
Metropolitan	.96212388	153,940
Ventura County Flood Control and Water Conservation District	.00860328	1,376
Santa Clarita Valley Water Agency	.02927284	4,684
Total Castaic Lake	1.00000000	160,000
Lake Perris[1]	1.00000000	65,000
Metropolitan		

[1] The 2003 Exchange Agreement among Metropolitan, CVWD, and DWA, among other things, transferred to CVWD and DWA a portion of Metropolitan's capacity in the California Aqueduct and the East Branch including Lake Perris. However, Metropolitan's rights to the full 65,000 AF of Lake Perris flexible storage account was retained by Metropolitan.

C. Metropolitan Surface Reservoirs

Source of Supply

Storage capacity in Metropolitan reservoirs, including Lake Skinner, Lake Mathews, Live Oak Reservoir, Garvey Reservoir, Palos Verdes Reservoir, Orange County Reservoir, and DVL, is earmarked to meet emergency, dry-year/seasonal, and system regulation needs, as these have been defined above.

Expected Supply Capability

The total available storage capacity for all Metropolitan-controlled surface reservoirs (Metropolitan-owned and DWR terminal reservoirs) is 1,632,000 AF. As discussed earlier, approximately 750,000 AF has been set aside to meet the emergency storage objective of the service area. After accounting for emergency storage, the surface storage available in Metropolitan-owned reservoirs to meet dry-year/seasonal requirements is presented in Table A.3-5.

Rationale for the Expected Supply

Program Facilities

Major facilities for Lake Mathews include an earthen dam to impound water and a recently completed new outlet tower. Major facilities for Lake Skinner include an earthen dam to impound water, an outlet tower, an inlet from the San Diego Canal to deliver water into the reservoir, a water treatment filtration facility, and recreational facilities consisting of a marina, parks, swimming areas, golf course, and hiking trails. Major facilities at DVL include three earthen dams to impound water, an inlet/outlet tower, a secondary inlet from the Inland Feeder, a large pumping station to deliver water into the reservoir, and power generating facilities. Recreational facilities consisting of a marina, parks, swimming areas, golf course, hiking trails, equestrian trails, and lodging are planned.

Historical Record

DVL has been operational for over 20 years. Lake Mathews and Lake Skinner have been in service since the 1940s and 1970s, respectively.

November 1974 Memorandum of Understanding and Agreement on Operation of Lake Skinner. This MOU and the January 2005 Amendment, signed by Metropolitan and other affected parties, govern Metropolitan's operations of Lake Skinner in Riverside County. The DWR Division of Safety and Dams also reviews monitoring data on the safety of the dam annually.

October 1991 Final EIR for the Eastside Reservoir Project (DVL). The EIR established criteria for integrating the operations of Metropolitan's reservoirs and DWR's southern reservoirs for emergency purposes. These criteria also provided that Metropolitan reservoirs could be expected to withdraw all drought storage water within a two-year period.

November 1994 Memorandum of Understanding on Operation of Domenigoni Valley Reservoir (now known as Diamond Valley Lake). This MOU, signed by Metropolitan and other affected parties, governs Metropolitan's operations of DVL in Riverside County. The DWR Division of Safety and Dams also reviews monitoring data on the safety of the dam annually.

June 2002 Division of Safety of Dams Certificate of Approval. The DWR Division of Safety of Dams issued the Certificate of Approval for operation of DVL in early 2000, with three conditions. These conditions were: (1) satisfactory operation of the butterfly valves and emergency gate in the inlet/outlet tower, (2) completion of the Tank Saddle Cutoff remediation, and (3) completion of the Signal Spillway. Metropolitan completed these conditions in 2001, and DVL is currently operational in accordance with the Certificate of Approval.

Table A.3-5
Estimated Supplies Available from Metropolitan's Surface Storage Program Capabilities
(acre-feet per year)

Forecast Year	Five Year Drought (1988-92)	Single Dry Year (1977)
2025	161,000	807,000
2030	161,000	809,000
2035	161,000	808,000
2040	161,000	808,000
2045	161,000	806,000

Source: Metropolitan analysis

Financing

The capital cost of DVL, Lake Mathews, and Lake Skinner was financed by a combination of revenue bonds and operating revenues. Annual operating costs, including maintenance and pumping, are included in Metropolitan's annual O&M budget (referenced above).

Federal, State, and Local Permits/Approvals

All necessary permits have been obtained. A permit to generate and sell power has been acquired from the Federal Energy Regulatory Commission. No further regulatory permits are required.

D. Groundwater Conjunctive Use Programs

Source of Supply

Metropolitan's IRP established the strategy to store imported water that is most available during wet years in surface reservoirs or groundwater aquifers for later use during droughts and emergencies. In this way, Metropolitan can reduce its reliance on direct deliveries from the SWP and the Colorado River during dry years when competing demands by other users and risks to the watershed ecosystems are greatest. Metropolitan has implemented a conjunctive use program for imported water storage in groundwater basins within the service area based upon policy principles adopted in 2000.

In 2007, Metropolitan published the Groundwater Assessment Study which estimated 3.2 MAF of available storage space in groundwater basins. Due to drought and the subsequent decline in water levels, it is estimated that storage in the groundwater basins has declined about 700 TAF from 2000 to 2019. Additionally, the 2020 IRP may lead to policies and strategies for ensuring sustainable groundwater production in light of a potential for extended multiple-year dry conditions.

Rationale for the Expected Supply

<u>Implementation Status</u>

The status of implementation for the groundwater conjunctive use programs has been described above.

<u>Historical Record</u>

In 2000, Metropolitan entered an agreement with DWR to administer $45 million of Proposition 13 state bond funds for Metropolitan's Southern California Water Supply Reliability Projects Program. Metropolitan paired the $45 million of state funds with $35 million of Metropolitan capital funds to develop nine groundwater storage programs in partnership with member and retail agencies and groundwater basin managers. These nine contractual storage programs have an initial 25-year term and provide for storage of up to 212 TAF and dry-year yield of up to 70 TAF. These programs are summarized in Table 3-16. Since inception, the conjunctive use program has been exercised to store water in groundwater basins during wet periods and relied upon to extract that water during dry periods. For example, during the recent drought period from 2012 to 2016, the conjunctive use program provided 64,000 AF of dry year supply to help Metropolitan meet regional demands. As of January 2020, the conjunctive use storage balance is 61,000 AF.

Metropolitan has also implemented a Cyclic Program to help capture additional imported supplies that would otherwise be lost to the region, when available storage capacity is limited. Under the Cyclic Program, Metropolitan delivers imported water supplies to the member agencies for storage in their local groundwater basin or surface water reservoir in advance of the demand for the water for a future use. The member agency purchases the water based on a mutually agreed upon schedule but has full discretion on the use of the stored water. The Cyclic Program creates additional flexibility for managing Metropolitan's water supplies.

Metropolitan has ten-year cyclic agreements with the City of Burbank, City of Pasadena, Calleguas Municipal Water District, Eastern Municipal Water District, Municipal Water District of Orange County, San Diego County Water Authority, and Western Municipal Water District. These agreements commenced between 2017 and 2019. In addition to these agreements, Metropolitan has existing agreements with two other member agencies. The Cyclic Storage Agreement with Upper San Gabriel Valley MWD allows pre-delivery and storage of up to 100 TAF of imported water. The agreement was originally signed in 1975 for a term of five years and has been extended in five-year increments. The agreement currently expires in November 2023. Metropolitan amended this agreement in August 2019 to increase the storage amount to up to 200 TAF. Metropolitan is working with Upper San Gabriel Valley MWD to enter into a new ten-year agreement. The Cyclic Storage Agreement with Three Valleys MWD allows for pre-delivery and storage of up to 40 TAF. This agreement was originally signed in 1991 for a term of five years and has been extended in five-year increments. Metropolitan entered into a new agreement that increased the storage amount to 50 TAF and expires in June 2030. Both agreements are expected to be renewed repeatedly in the future.

<u>Written Contracts or Other Proof</u>

Metropolitan's dry-year supply from the groundwater conjunctive use programs is based on Metropolitan's Board actions and agreements.

Proposition 13 Groundwater Conjunctive Use Programs.

Metropolitan Water District published the Groundwater Assessment Study Report in 2007 in collaboration with its member agencies and groundwater basin managers documenting existing use and development of groundwater resources in Metropolitan's service area and estimating additional groundwater basin storage potential.

Principles for groundwater storage adopted by the Metropolitan Board in January 2000.

Resolution for Proposition 13 Funds adopted by the Metropolitan Board in October 2000.

Agreement executed with the DWR for Interim Water Supply Construction Grant Commitment Safe Drinking Water, Clean Water, Watershed Protection and Flood Protection (Proposition 13, Chapter 9, Article 4) providing for Metropolitan to administer $45 million in state Proposition 13 grant funds for groundwater reliability programs; October 2000.

Agreement executed for Long Beach Conjunctive Use Project, July 2002, amended in July 2003, October 2005, and November 2008.

Agreement executed for Live Oak Conjunctive Use Project, October 2002.

Agreement executed for Foothill Area Groundwater Storage Project, February 2003, amended in August 2006, April 2008, and February 2009.

Agreement executed for Chino Basin Programs, June 2003, amended in May 2004, August 2004, August 2005, May 2008, March 2009, September 2009, July 2010, and January 2015.

Agreement executed for Orange County Groundwater Storage Program, June 2003, amended in July 2004, December 2005, and July 2008.

Agreement executed for Compton Conjunctive Use Program, February 2005.

Agreement executed for Long Beach Conjunctive Use Project — Expansion in Lakewood, July 2005, amended in April 2006, August 2007, November 2008, and February 2010.

Agreement executed for Upper Claremont Basin Groundwater Storage Program, September 2005, amended in April 2008.

Agreement executed for Elsinore Basin Conjunctive Use Program, December 2006, amended in May 2008.

All of these programs have an initial 25-year term, with provision for renewal or extension after that period.

Financing

Financing has been supplied from multiple sources as discussed below:

Financing from Proposition 13 and Additional Groundwater Storage Programs.

Proposition 13 funds ($45 million) were allocated to Metropolitan by the state in May 2000 for the development of local groundwater storage projects.

Metropolitan has executed groundwater storage funding agreements for nine storage programs, expended $45 million of the Proposition 13 funds, and appropriated over $35 million of Metropolitan capital funds for the storage programs in the Orange County and Chino groundwater basins. All nine storage programs have completed facilities and are currently active. Metropolitan began calling for production of stored water beginning in 2007.

Table A.3-6 provides details on groundwater storage programs.

Federal, State, and Local Permits/Approvals

Long Beach Conjunctive-use Storage Project. Environmental documentation for the Long Beach Conjunctive-use Storage Project was certified by the City of Long Beach in August 2001.

Live Oak Basin Conjunctive-use Storage Project. Environmental documentation for the Live Oak Basin Conjunctive-use Storage Project was certified by Three Valleys MWD in January 2002.

Foothill Area Groundwater Storage Project. Environmental documentation for the Foothill Area Groundwater Storage Project was certified by Foothill Municipal Water District in January 2003.

Chino Basin Programs Groundwater Storage Project. Environmental documentation for the Chino Basin Programs Groundwater Storage Project was certified by Inland Empire Utility Agency in December 2002.

Long Beach Conjunctive Use Storage Project – Expansion in Lakewood. Environmental documentation for the project was certified by the City of Lakewood in May 2005.

City of Compton Conjunctive Use Program. Environmental documentation for the project was certified by the City of Compton in December 2004.

Orange County Groundwater Conjunctive Use Program. Environmental documentation for the project was certified by Orange County Water District in March 1999 and in July 2002.

Upper Claremont Basin Groundwater Storage Program. Environmental documentation for the project was certified by Three Valleys MWD in July 2005.

Elsinore Basin Conjunctive Use Program. Environmental documentation for the project was certified by Elsinore Valley MWD in February 2004.

E. Program under Development

Regional Recycled Water Program

The Regional Recycled Water Program (RRWP), a partnership with the Los Angeles County Sanitation Districts, will purify wastewater to produce high quality water that could be used again. The RRWP would produce up to 150 MGD of purified water from the Joint Water Pollution Control Plant in Carson for groundwater replenishment, industrial use, and potentially raw water augmentation. The agencies have been working together for over 10 years on the program. As a first step toward full implementation, Metropolitan and the Sanitation Districts cooperated to complete the Advanced Purification Center in 2019. The Advanced Purification Center is a 0.5 million gallon per day demonstration facility that will generate information needed for the potential future construction of a full-scale recycled water facility. It uses a unique application of membrane bioreactors designed to significantly increase efficiency in water recycling. Scientists and engineers will test the process, utilizing full-scale treatment modules, to ensure the resulting purified water meets the highest water quality standards. Once approved by regulators, this innovative process could be used throughout California and even applied around the globe.

Metropolitan and the Sanitation Districts are continuing to move forward with the program, to enhance their partnership and begin the next phase of the program. Metropolitan's Board approved proceeding with the environmental planning phase of the project in November 2020.

Table A.3-6
Metropolitan's In-Region Groundwater Storage Programs

Program	Metropolitan Agreement Partners	Program Term	Max Storage AF	Dry-Year Yield AF/Yr

Appendix 4

WATER SHORTAGE CONTINGENCY PLAN

Appendix 4
WATER SHORTAGE CONTINGENCY PLAN

This Water Shortage Contingency Plan (WSCP) complies with California Water Code (CWC) Section 10632, which requires that every urban water supplier shall prepare and adopt a WSCP as part of its urban water management plan (UWMP). Section 10632.2 provides, "An urban water supplier shall follow, where feasible and appropriate, the prescribed procedures and implement determined shortage response actions in its water shortage contingency plan...or reasonable alternative actions, provided that descriptions of the alternative actions are submitted with the annual water shortage assessment report pursuant to Section 10632.1." Notwithstanding, the CWC does not prohibit an urban water supplier from taking actions not specified in its WSCP, if needed, without having to formally amend its UWMP or WSCP.

The WSCP is a guide for the Metropolitan Water District of Southern California's (Metropolitan's) intended actions during water shortage conditions. It is meant to improve preparedness for droughts and other impacts on water supplies by describing the process used to address varying degrees of water shortages. Certain elements of the WSCP are required by the CWC, including response actions that align with six standard water shortage levels based on water supply conditions, as well as shortages resulting from catastrophic supply interruptions. The WSCP also describes Metropolitan's procedures for conducting an Annual Water Supply and Demand Assessment (Annual Assessment) that is required by CWC Section 10632.1 and is to be submitted to the California Department of Water Resources (DWR) on or before July 1 of each year, or within 14 days of receiving final allocations from the State Water Project (SWP), whichever is later.

Metropolitan's WSCP is included as Appendix 4 to its 2020 UWMP which will be submitted to DWR by July 1, 2021. However, this WSCP is created separately from Metropolitan's 2020 UWMP and can be amended, as needed, without amending the UWMP.

Organization of this Document

The WSCP covers the required elements as set forth by CWC Section 10632. Because Metropolitan is a wholesale urban water supplier, elements that pertain only to retail water suppliers are not addressed in this WSCP.[1] The document contains eight sections. Section A.4.1 is an introduction that explains the purpose of the WSCP and provides background on Metropolitan's service area and system. Section A.4.2 is a summary of the water supply analysis and water reliability findings from the 2020 UWMP, pursuant to CWC Section 10635. Section A.4.3 is a description of procedures to conduct and approve the Annual Assessment. Section A.4.4 explains the WSCP's six standard water shortage levels corresponding to progressive ranges of up to 10, 20, 30, 40, 50, and more than 50 percent shortages and describes the WSCP's shortage response actions that align with the defined shortage levels. Section A.4.5 addresses communication protocols and procedures to inform customers, the public, interested parties, and local, regional, and state governments regarding any current

[1] WSCP elements that apply specifically to retailer water suppliers are: (1) a description of customer compliance, enforcement, appeal, and exemption procedures for triggered response actions (CWC Section 10632(a)(6)); (2) a description of the cost of compliance with Chapter 3.3 (commencing with Section 365) of Division 1 (CWC Section 10632(a)(8)(c)); and (3) monitoring and reporting requirements and procedures that ensure appropriate data is collected, tracked, and analyzed for purposes of monitoring customer compliance and to meet state reporting requirements (CWC Section 10632(a)(9)).

or predicted shortages and any resulting shortage response actions. Section A.4.6 is a description of the legal authorities that enable Metropolitan to implement and enforce its shortage response actions. Section A.4.7 is a description of the financial consequences of and responses for drought conditions. Section A.4.8 addresses reevaluation and improvement procedures for monitoring and evaluating the functionality of the WSCP and describes the process to adopt, submit, and amend the WSCP.

A.4.1 Background Information on Metropolitan

Background

Metropolitan is a public agency organized in 1928 by a vote of the electorate of 13 Southern California cities. The agency was enabled by the adoption of the original Metropolitan Water District Act (MWD Act) by the California Legislature "for the purpose of developing, storing, and distributing water for domestic purposes." The MWD Act also allows Metropolitan to sell "surplus water not needed or required for domestic or municipal uses within the district for beneficial purposes." In 1992, the Metropolitan Board of Directors adopted the following mission statement:

> *"To provide its service area with adequate and reliable supplies of high-quality water to meet present and future needs in an environmentally and economically responsible way."*

Water used in Southern California comes from several sources. The investments that Metropolitan has made and its ongoing efforts in many different areas coalesce toward its goal of long-term regional water supply reliability. The first function of Metropolitan was building the Colorado River Aqueduct (CRA) to convey water from the Colorado River. Deliveries through the CRA to member agencies began in 1941 and supplemented the local water supplies of the Southern California member cities. In 1960, to meet growing water demands in its service area, Metropolitan contracted with DWR for participation in the SWP, which delivers water to Metropolitan's service area via the California Aqueduct. SWP deliveries began in 1972. Metropolitan currently receives imported water from both of these sources: (1) Colorado River via the CRA, and (2) the SWP via the California Aqueduct. Beyond its core imported supplies from the Colorado River and SWP, Metropolitan actively supports efforts to develop storage and groundwater management programs, and to increase conservation, water recycling, groundwater recovery, and seawater desalination projects.

Service Area

Metropolitan's service area covers the Southern California coastal plain. It extends about 200 miles along the Pacific Ocean from the city of Oxnard to the north to the international boundary with Mexico to the south, and it reaches as far as 70 miles inland from the coast. The total area served is approximately 5,200 square miles, and it includes portions of Los Angeles, Orange, Riverside, San Bernardino, San Diego, and Ventura counties. Table A.4-1 shows that although only 14 percent of the land area of the six Southern California counties is within Metropolitan's service area, approximately 86 percent of the population of those counties resides within Metropolitan's boundaries.

Table A.4-1
July 1, 2020 Area and Population in the
Six Counties of Metropolitan's Service Area

County	Total County	In Metropolitan Service Area	Percent in Metropolitan
Land Area (Square Miles)			
Los Angeles County	4,061	1,408	35%
Orange County	789	699	89%
Riverside County	7,208	1,057	15%
San Bernardino County	20,052	242	1%
San Diego County	4,200	1,420	34%
Ventura County	1,845	365	20%
Metropolitan's Service Area	**38,155**	**5,191**	**14%**
Population (Persons)			
Los Angeles County	10,172,000	9,275,000	91%
Orange County	3,191,000	3,184,000	100%
Riverside County	2,449,000	1,813,000	74%
San Bernardino County	2,184,000	872,000	40%
San Diego County	3,352,000	3,261,000	97%
Ventura County	841,000	630,000	75%
Metropolitan's Service Area	**22,189,000**	**19,035,000**	**86%**

Metropolitan is currently composed of 26 member agencies, including 14 cities, 11 municipal water districts, and one county water authority. Metropolitan is a water wholesaler with no retail customers. It provides treated and untreated water to its member agencies.

Metropolitan's 26 member agencies deliver to their customers a combination of local groundwater, local surface water, recycled water, desalinated seawater, and imported water received from Metropolitan. For some member agencies, Metropolitan supplies all the water used within that agency's service area, while others obtain varying amounts of water from Metropolitan to supplement local supplies. Between 2011 and 2020, Metropolitan has provided between 40 and 50 percent of the municipal, industrial, and agricultural water used in its service area. The remaining water supply comes from local wells, local surface water, recycling, and the city of Los Angeles' aqueducts from the Owens Valley/Mono Basin east of the Sierra Nevada. Member agencies also implement conservation programs that can be considered part of their supplies.

Some member agencies provide retail water service, while others provide water to their local area as wholesalers. Table A.4-2 shows Metropolitan's member agencies and the type of service that they provide. As shown in the table, 15 member agencies provide retail service to customers, nine provide only wholesale service, and two provide a combination of both. Metropolitan's member agencies serve residents in 152 cities and 89 unincorporated communities. Throughout Metropolitan's service area, approximately 250 retail water suppliers directly serve the population.

Reliability Planning

Metropolitan continuously engages in planning for various aspects of its water management, including operations, long-term reliability, and emergency response. These planning efforts include the 1996 Integrated Water Resources Plan (IRP) and its three updates in 2004, 2010, and 2015; the 2020 IRP (currently in development); the WSCP; the Water Surplus and Drought Management (WSDM) Plan; the Water Supply Allocation Plan (WSAP); the Emergency Storage Objective; and the Seismic Risk Assessment and Mitigation Plan. Collectively, they provide a policy framework, operating guidelines, and resource targets for Metropolitan to ensure regional water supply reliability.

The IRP is Metropolitan's evolving long-term plan to assure adequate water supplies for Southern California. The first IRP was adopted in 1996 to address the complexity of developing, maintaining and delivering water to meet changing demands in the face of growing challenge. The IRP has been updated several times over the past 25 years. In 2020, Metropolitan started development of a new IRP that incorporates planning for multiple future scenarios to address an extended range of uncertainty. While Metropolitan coordinates regional supply planning through its inclusive IRP process, Metropolitan's member agencies also conduct their own planning analyses, including their own urban water management plans, and may develop projects independently of Metropolitan.

The WSCP is designed to be consistent with the WSDM Plan and the WSAP described below. Throughout the year, Metropolitan evaluates member agency demands, available water supplies, and existing water storage levels on a monthly basis to determine the appropriate actions identified in the WSDM Plan.

The 1999 WSDM Plan provides policy guidance for managing regional water supplies during surplus and shortage conditions. Similar in concept to the WSCP, the WSDM Plan provides an overall vision for operational supply management and characterizes a flexible sequence of actions to minimize the probability of severe shortages and reduce the likelihood of extreme shortages. WSDM Plan principles guide the specific actions to be taken under WSCP shortage stages (see section A.4.4). Data collection, continual analysis, and monthly reporting processes of WSDM Plan implementation will form the basis for Metropolitan's Annual Water Supply Demand Assessment that will be provided annually to the state beginning in July 2022. The WSDM Plan is included as Attachment A to this WSCP.

The WSAP is Metropolitan's policy and formula for equitably allocating available water supplies to the member agencies during extreme water shortages when Metropolitan determines it is unable to meet all of its demands. The WSAP is included as Attachment B to this WSCP.

The Emergency Storage Objective is the regional planning estimate for emergency storage, which represents the amount of water that Metropolitan would hold in storage for the region in preparation for a catastrophic earthquake that would damage the aqueducts that transport imported water supplies to Southern California: the CRA, both the East and West branches of the California Aqueduct, and the Los Angeles Aqueduct. In 2019, Metropolitan and its member agencies completed a process to update the planning estimate of Metropolitan's Emergency Storage Objective. The emergency storage allows Metropolitan to deliver reserve supplies to the member agencies to supplement local production. This helps avoid severe water shortages during periods when the imported water aqueducts may be out of service.

Beginning January 2020, CWC Section 10632.5 mandates urban water suppliers to include in their UWMP a seismic risk assessment and mitigation plan to assess the vulnerability of each of the various facilities of a water system and mitigate those vulnerabilities. For Metropolitan, this requirement was addressed as part of developing its resilience strategy and is presented in detail in Metropolitan's seismic resiliency reports in Appendix 9 to the 2020 UWMP, which are incorporated herein by reference.

A.4.2. Analysis of Water Supply Reliability

Besides the WSCP, the Urban Water Management Planning Act requires suppliers to conduct two other planning analyses to evaluate supply reliability. The first is a Water Reliability Assessment that compares the total water supply sources available to the water supplier with long-term projected water use over the next 20 years, in five-year increments, for a normal water year, a single dry water year, and a drought lasting five consecutive water years. The second is a Drought Risk Assessment that evaluates a drought period that lasts five consecutive water years starting from the year following when the assessment is conducted.

Metropolitan completed its Water Reliability Assessment and Drought Risk Assessment as part of the 2020 UWMP. Through the Water Reliability Assessment, Metropolitan determined that, under the conditions required by the Urban Water Management Planning Act, it has supply capabilities sufficient to meet expected demands from 2025 through 2045 under a single dry-year condition and a period of drought lasting five consecutive water years, as well as in a normal water year hydrologic condition. Metropolitan's near-term Drought Risk Assessment revealed that its supply capabilities are expected to exceed its projected water use for the year 2022. However, estimates of projected water supply and use reveal that there could be a possible shortfall of core supplies in 2021, 2023, 2024, and 2025. This shortfall is largely triggered by the assumed low supply conditions from the SWP under a repeat of the historical condition of 1988 to 1992, which is modeled at 12% for 2021, 15% for 2023, 23% for 2024, and 18% for 2025. Actual supply conditions for the next five years may prove different from historic supply conditions. The WSCP shows Metropolitan's potential shortage response actions if such shortfalls were to happen. The Drought Risk Assessment projected supplies and demands for the years 2021 through 2025 using the driest five-year sequence.

Metropolitan's principal sources of water supplies are the SWP and the Colorado River. Metropolitan receives water delivered from the SWP under State Water Contract provisions, including contracted supplies, use of carryover storage in San Luis Reservoir, and surplus supplies. Metropolitan holds rights to Colorado River water for CRA diversion at Lake Havasu. Water management programs supplement these Colorado River supplies. To secure additional supplies, Metropolitan has groundwater banking partnerships and water transfer and storage arrangements within and outside its service area.

Hydrologic conditions and environmental regulations can have a significant impact on Metropolitan's imported water supply sources. For Metropolitan's SWP supplies, precipitation in California's northern Sierra Nevada during the fall and winter helps replenish storage levels in Lake Oroville, a key SWP facility. The source of Metropolitan's Colorado River supplies is primarily the watersheds of the Upper Colorado River Basin in the states of Colorado, Utah, and Wyoming. Although precipitation is primarily observed in the winter and spring, summer storms are common and can affect water supply conditions. Hydrologic variability, potential climate change, and regulatory risk are embedded in Metropolitan's modeling efforts. Metropolitan's modeling utilizes historical hydrologic conditions from 1992 to 2017 to simulate expected demands on Metropolitan supplies, as well as capacities and constraints of its storage facilities and supply programs. While potential impacts from climate change remain subject to study and debate, climate change is among the uncertainties that Metropolitan seeks to address through its various planning processes. Metropolitan's 2020 IRP is further addressing ways to account for and mitigate these uncertainties.

As demonstrated by the findings of both the Water Reliability Assessment and the Drought Risk Assessment, Metropolitan is able to mitigate the challenges posed by hydrologic variability, potential climate change, and regulatory risk on its imported supply sources through the significant storage capabilities it has developed over the last two decades, both dry-year and emergency storage.

A.4.3. Annual Water Supply and Demand Assessment Procedures

As an urban water supplier, Metropolitan is required under CWC Section 10632(a)(2) to prepare and submit an "annual water supply and demand assessment" (Annual Assessment). The Annual Assessment is a determination of Metropolitan's near-term outlook for supplies and demands and how a perceived shortage may relate to WSCP shortage stage response actions in the current calendar year. This determination will be based on known circumstances and information available to Metropolitan at the time of analysis. Starting in 2022, the Annual Assessment will be due by July 1 of every year, as indicated by CWC Section 10632.1. CWC Section 10632.1 also states that *"[a]n urban water supplier that relies on imported water from the State Water Project or the Bureau of Reclamation shall submit its annual water supply and demand assessment within 14 days of receiving its final allocations, or by July 1 of each year, whichever is later*." The Annual Assessment and related reporting are to be conducted based on the procedures described in this WSCP. This section describes Metropolitan's procedures for conducting the Annual Assessment, which include: (1) the written decision-making process to determine water supply reliability; and (2) the key data inputs and assessment methodology to evaluate water supply reliability for the current year and one dry year.

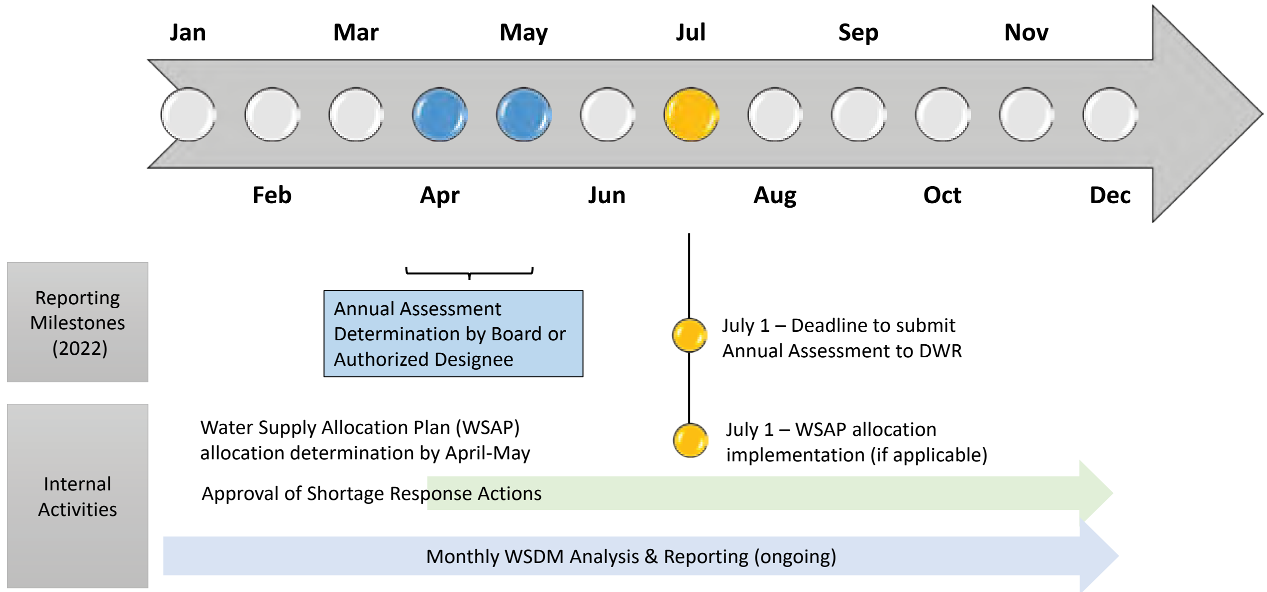
Steps to Approve the Annual Assessment Determination

The Annual Assessment will be primarily based on Metropolitan's ongoing WSDM supply-demand tracking process which is exhibited in monthly reporting to the Board of Directors throughout the year. WSDM planning activities involve examination of developing demand and supply conditions for the calendar year, as well as considerations of potential actions consistent with the WSDM Plan. These monthly analyses provide key information for Metropolitan to manage resources to meet a range of estimated demands and adjust to changing conditions throughout the year.

As a water supply wholesaler, Metropolitan's water demands are a function of retail-level demands and local water production. Water from Metropolitan serves as a supplemental source of supply for its 26 member agencies. For many member agencies, their primary source of water is produced locally from groundwater basins, surface reservoirs, recycled water projects, groundwater recovery projects, and seawater desalination. When local supplies are not enough to meet retail demands, member agencies purchase supplemental water from Metropolitan. Some member agencies rely heavily on Metropolitan due to limited local supplies. As described below, Metropolitan collects estimates of projected consumptive and replenishment water demands from its member agencies. This information is adjusted to determine unconstrained demands for the purpose of the Annual Assessment shortage percentage evaluation.

By June, Metropolitan staff will present a completed Annual Assessment for approval by the Board of Directors or by the Board's authorized designee with expressly delegated authority for approval of Annual Assessment determinations. This presentation will include a request that the approval of the Annual Assessment determination also appropriately triggers any recommended specific shortage response actions resulting from the assessment. Upon approval, Metropolitan staff will then formally submit the Annual Assessment to DWR by July 1. Figure A.4-1 provides a graphic representation of the decision-making process.

Figure A.4-1
Sample Annual Assessment Decision-Making Timeline



Data Inputs and Assessment Methodology

This section describes how Metropolitan will evaluate water supply reliability for the current year and one dry year for the purpose of the Annual Assessment. The Annual Assessment determination will be based on considerations of available core water supplies, unconstrained water demand, and infrastructure considerations. The difference between core water supplies and unconstrained demand will be used to determine what, if any, shortage stage is expected under the WSCP framework. The standard shortage stage percentage will be calculated by dividing the difference between core supplies and unconstrained demand by unconstrained demand. This calculation will be performed separately for anticipated current year conditions and for an assumed dry year condition.

Locally Applicable Evaluation Criteria

Because shortages are based on the difference between expected core supplies and unconstrained demand under current year and dry year conditions, the locally-applicable evaluation criteria to be used in the Annual Assessment for determining a shortage include the following:

- Characterization of current year and dry year scenarios based on best-available data, including anticipated hydrologic conditions for Metropolitan's supply source watersheds in the Colorado River basin and Northern California, as well as for local conditions in Metropolitan's service area in Southern California.
- Estimation of available core supplies (see below) for current year and dry year scenarios
- Estimation of unconstrained demands (see below) for current year and dry year scenarios

Together, these three criteria provide the necessary information to calculate shortage percentages by dividing the difference between core supplies and unconstrained demand by unconstrained demand, under current year and dry year scenarios. These criteria findings will also be given additional context and influenced by infrastructure considerations discussed below which will differ from year to year.

The information and analyses that comprise the Annual Assessment will be based on ongoing planning processes that include the monthly WSDM supply-demand reporting. The Annual Assessment represents a mid-year evaluation at a given point in time; even after formal approval and submittal of the Annual Assessment determination by July 1, Metropolitan will continue to monitor emerging supply and demand conditions and take appropriate actions consistent with the flexibility and adaptiveness inherent to this WSCP. Some locally-applicable conditions that affect Metropolitan's wholesale supply and demand, such as the Higher Priority Water Use Adjustment for Colorado River use (see below), local supply production, annual SWP allocations, the status of Metropolitan storage accounts, the status of the local groundwater basins, changed water use practices, and local economic activity entail a high degree of uncertainty and can differ significantly from earlier projections throughout the year.

Description and Quantification of Each Source of Water Supply (Core Supplies)

Metropolitan's core water supplies are counted as the supply component of the Annual Assessment. Core supplies include estimated water supplies from the Colorado River and the SWP for the current year. Imported core supplies vary from year to year and are influenced by annual weather and hydrology, as well as demand by other higher priority users and operational and regulatory factors.

Because core supplies are used every year, they are differentiated from the WSCP's shortage response actions for supply augmentation; supply augmentation actions are comprised of Metropolitan's portfolio of water storage reserves and flexible supply sources that are available on an as-needed basis.

Metropolitan's core supplies come from several programs, which are shown in Table A.4-3 and described below.

Table A.4-3
Core Water Supplies

Source	Core Supply
Colorado River	Colorado River Basic Apportionment Higher Priority Water Use Adjustment to Colorado River Basic Apportionment IID/MWD Conservation Program PVID Fallowing Program Bard Water District Seasonal Fallowing Program Lower Colorado Water Supply Project Exchange with SDCWA Exchange with the United States
State Water Project	MWD SWP Table A SWP Article 21 Interruptible Supplies SWP Port Hueneme Lease of Ventura Table A Desert Water Agency/Coachella Valley Water District/Metropolitan Water Exchange and Advance Delivery Programs San Gabriel Valley Municipal Water District Program

Colorado River

Colorado River Basic Apportionment

Metropolitan built, owns, and operates the 242-mile CRA. The CRA originates at Lake Havasu on the Colorado River and winds through a series of pump stations and reservoirs through the California desert to its terminal reservoir at Lake Mathews in Riverside County. The CRA has a full delivery capacity of about 1.25 MAF.

The state of California holds a 4.4 MAF per year normal apportionment to Colorado River water. Metropolitan has the Fourth Priority right to normal apportionment of 550,000 AF per year of the State's normal apportionment. Metropolitan also holds the Fifth Priority right for an additional 662,000 AF per year which is utilized during surplus conditions or when supplies from other Colorado River users are available.

Higher Priority Water Use Adjustment to Metropolitan's Colorado River Basic Apportionment

Entitlements to use Colorado River water in California under priorities 1, 2, and 3 are limited to 3.85 MAF per year. Priority 3(a) is held by the Imperial Irrigation District and the Coachella Valley Water District (CVWD) totaling 3.43 MAF. After accounting for contractual conservation and transfers, any unused volume available to Priority 3(a) becomes available for use by Metropolitan. Of the 3.85 MAF, the remaining 420,000 AF is available for use under priorities 1, 2, and 3(b) held by the Palo Verde Irrigation District and the Yuma Project lands within California. Any unused amount from this volume is available for use by Metropolitan, however, Metropolitan must forego its otherwise available Colorado River supplies to meet annual uses under priorities 1, 2, and 3(b) that are in excess of 420,000 AF. Lastly, there are additional high-priority "present perfected rights" within California not incorporated into the priorities, for which Metropolitan must forego its otherwise available Colorado River supplies to meet uses of present perfected rights that exceed 14,500 AF. The net sum of these volumes is the "higher priority water use adjustment" to Metropolitan's base supply.

Imperial Irrigation District-Metropolitan Conservation Program

Since 1988, Metropolitan has funded water conservation programs within Imperial Irrigation District's (IID) service area. The amount of water conserved from these programs is then transferred to Metropolitan. Conservation approaches range from distribution system improvements (such as canal lining, spill capture and the installation of non-leak irrigation gates) to efficient on-farm water management practices (such as delivering water to farmers on a 12-hour rather than a 24-hour basis). Through this program, a total of 105,000 AF per year of water is conserved and made available to Metropolitan.

Palo Verde Irrigation District Land Management, Crop Rotation and Water Supply Program

In 2005, Metropolitan entered a 35-year program with the Palo Verde Irrigation District (PVID). Under the program, participating farmers in PVID are paid to reduce their water use by leaving acreage unirrigated. A base amount of 25 percent of the program acreage must be fallowed every year. Metropolitan may elect to call for additional acreage to be fallowed up to 90.3%. Fallowing calls must be made at least one year in advance by July 31 of each year and would take effect on August 1 of the following year. The reduced consumptive use due to fallowed lands reduces uses under priorities 1, 2, and 3(b), thereby increasing the Colorado River water supply available to Metropolitan. The fallowing program saves a minimum of 33,000 AF per year and up to 133,000 AF in certain years.

Metropolitan/Bard Seasonal Fallowing Program

At its December 2019 meeting, Metropolitan's Board authorized a 7-year seasonal fallowing program with the Bard Water District (Bard). Under the program, participating farmers in Bard are being paid to reduce their water use by not irrigating a portion of their land. A maximum of 3,000 acres can be fallowed in any given year. Under the terms of the QSA, water savings within the Bard service area are made available to Metropolitan. Bard Unit, as part of the Yuma Project, has the first priority for Colorado River water under the water delivery contracts with the USBR. Implementation of the program began in March 2020. It is estimated that the Seasonal Fallowing Program would provide up to 6,000 AF per year of additional Colorado River water. This water would be available in any year as needed and in accordance with the provisions described in the agreements with Bard Unit farmers and Bard.

Lower Colorado Water Supply Project

Groundwater is pumped by the Lower Colorado Water Supply Project near the All-American Canal and is discharged to the Canal. IID reduces its net diversions of Colorado River water by an amount equal to the amount of Project water discharged into the Canal, permitting entities along the Colorado River that do not have rights or have insufficient rights to divert Colorado River water to obtain a supply of water. In 2007, Metropolitan entered into a contract with the USBR and the City of Needles to utilize the unused Project capacity.

Exchange with the San Diego County Water Authority (SDCWA)

SDCWA has acquired conserved Colorado River water reaching an annual volume of 277.7 TAF by 2023. SDCWA makes this water available at Lake Havasu for Metropolitan diversion, where Metropolitan takes possession of the water and provides a matching volume from Metropolitan's blended supplies to SDCWA by exchange in equal monthly amounts. The conserved water is acquired by SDCWA through its transfer agreement with IID and from the lining of the All-American and Coachella canals.

Under the transfer agreement with IID, the stabilized annual transfer volume of 200 TAF is generated from conservation of water through on-farm efficiency conservation arrangements made by IID with its customers and other system efficiency measures.

The Coachella Canal Lining Project consists of a 35-mile concrete-lined canal, including siphons, which replaced an earthen canal. The project was completed in December 2006 and conserves 30,850 AF annually. The All-American Canal Lining Project consists of a concrete-lined canal constructed parallel to 23 miles of earthen canal and was completed in 2009, conserving 67,700 AF annually.

Pursuant to the QSA and related agreements, the 98,550 AF of water resulting from these projects annually is allocated as follows: 16,000 AF to the San Luis Rey Settlement Parties in San Diego County, 77,700 AF to SDCWA, and 4,850 AF for Coachella Canal Lining Project mitigation.

Exchange with the United States

Of the 16 TAF allocated to the San Luis Rey Settlement Parties from the All-American and Coachella canal lining projects, the United States furnishes this water at Metropolitan's Colorado River Intake on Lake Havasu. Metropolitan takes possession of the water and by exchange delivers an equal volume of Metropolitan's blended supplies to SDCWA. By separate agreement, SDCWA conveys the water to the San Luis Rey Settlement Parties. So long as water conserved by the All-American Canal Lining Project and Coachella Canal Lining Project is allocated to and available for use by the San Luis Rey Settlement Parties, the United States will make 16 TAF available for diversion by Metropolitan in perpetuity.

State Water Project

Table A Contract Amount

In accordance with its participation contract with DWR, Metropolitan's basic contract amount is for 1,911,500 AF per year. This represents the amount of water supply that would be available to Metropolitan in years where there is sufficient water supply for the SWP to deliver 100 percent of its total contract amounts. The amount of supply actually available on an annual basis is allocated to the State Water Contractors based on their proportionate Table A amounts.

DWR estimates the amount of supplies that are available each year. Metropolitan uses a forecasting method for SWP deliveries based on historical patterns of precipitation, runoff and actual deliveries of water. Annual SWP allocations have ranged from 5 percent to 100 percent of the Table A contract amounts.

Article 21 Interruptible Supplies

Metropolitan has a contract to water supplies that are made available on an intermittent basis. Storm flows can occasionally make water supplies available that are in excess to the Table A allocation. State Water Contractors can take delivery of these supplies, with their rights being based on their proportional Table A contract amounts. Historically, Article 21 interruptible supplies have ranged from 0 to 240,000 AF annually.

SWP Port Hueneme Lease of Ventura Table A

Metropolitan has a right to delivery of up to 1,850 AF of Table A supply from the Ventura County Watershed Protection District (Ventura), one of 29 SWP contractors, via a sublease agreement with the Port Hueneme Water Agency (Port Hueneme). United Water Conservation District, one of three agencies holding a contract right to Ventura Table A supply, leases this portion of their total 5,000 AF of Table A supply to Port Hueneme, which in turn subleases the Table A supply to Metropolitan. The long-term lease is a condition of the 1996 annexation of the Port Hueneme service area to Calleguas Municipal Water District and Metropolitan. This water supply is in addition to Metropolitan's Table A, and the amount available each year is determined by the SWP allocation, with 1,850 AF available at a 100 percent allocation.

Desert Water Agency/Coachella Valley Water District/Metropolitan Water Exchange and Advance Delivery Programs

The Desert Water Agency (DWA) and CVWD, both in Riverside County, have rights to SWP deliveries, but do not have any physical connections to the SWP facilities. Both agencies are adjacent to the CRA. For DWA and CVWD to obtain water equal to their SWP allocations, Metropolitan has agreed to exchange an equal quantity of its Colorado River water for DWA and CVWD's SWP water. DWA has a SWP Table A contract right of 55.75 TAF per year, and CVWD has a SWP Table A contract right of 138.35 TAF per year, for a total of 194.1 TAF per year. Additionally, CVWD has a long-term water supply agreement for 9.5 to 16.5 TAF annually from Rosedale Rio-Bravo Water Storage District.

Under the existing agreements, Metropolitan provides water from its CRA to DWA and CVWD in exchange for SWP deliveries. Metropolitan can deliver additional water to its DWA/CVWD service connections, permitting these agencies to store water. When supplies are needed, Metropolitan can then receive its full Colorado River supply, as well as the SWP allocation from the two agencies, while the two agencies can rely on the stored water for meeting their water supply needs. The amount of DWA and CVWD SWP Table A water available to Metropolitan depends on total SWP deliveries and varies from year to year.

In addition to their Table A and long-term water supplies, DWA and CVWD, subject to available capacity, may take delivery of SWP supplies available under Article 21, the Turn-back Pool Program, and non-SWP water supplies they may acquire and convey through the SWP facilities. These other supplies are delivered to DWA and CVWD by exchange with Metropolitan in the same manner as Table A deliveries. DWA and CVWD are participants in the Yuba Dry Year Water Purchase Program. Additionally, DWA participated in the 2009 Drought Water Bank and the 2015-2016 Multi-Year Water Pool Demonstration Program.

San Gabriel Valley Municipal Water District Program

The San Gabriel Valley Municipal Water District Program allows Metropolitan to exchange supplies to provide additional water for normal and dry year needs. Under this program, Metropolitan delivers supplies to the City of Sierra Madre, a San Gabriel Valley Municipal Water District member agency. In exchange for Metropolitan delivering one AF, San Gabriel Valley Municipal Water District returns two AF to Metropolitan in the Main San Gabriel Basin, up to 5 TAF. For any exchange amount less than 5 TAF, Metropolitan purchases the balance of the 5 TAF. The program provides increased reliability to Metropolitan by allowing additional water to be delivered to Metropolitan member agencies that rely upon the Main San Gabriel

Basin for their supplies – Three Valleys Municipal Water District and Upper San Gabriel Valley Municipal Water District.

Unconstrained Demands

For the purpose of the Annual Assessment and WSCP, CWC Section 10632(a)(2)(B)(i) directs Metropolitan to use current year "unconstrained demand" when assessing water supply reliability. The WSCP and Annual Assessment define unconstrained demand as expected water use in the current assessment year, based on recent water use, and before any projected shortage response actions that may be taken under the WSCP. Unconstrained demand is distinguished from observed demand, which may be constrained by preceding, ongoing, or future actions, such as emergency supply allocations during a multi-year drought. WSCP shortage response actions, if any are in place, that result in extraordinary demand reductions in the current year to constrain demand are inherently extraordinary; routine activities such as ongoing conservation programs and regular operational adjustments are not considered as constraints on demands.

To forecast near-term demands, Metropolitan begins by gathering data from its member agencies. In July of each year, member agencies submit their five-year demand forecasts to Metropolitan. Metropolitan uses this information as the foundation for forecasting demands. As the year progresses, the member agency forecasts are compared to the current demand trend. This comparison allows Metropolitan to adjust member agency forecasts to current conditions, while collaborating with member agencies as needed.

Metropolitan builds upon member agency demand projections to develop its own near-term forecast for its monthly WSDM supply-demand reporting. This forecast considers additional factors such as historical demand trends, changes in local supply production, weather trends, water-use efficiency trends, retail demand estimates, and updated estimates from member agencies.

Because these forecasted demands would be "constrained" observed demands rather than unconstrained demands, Metropolitan will adjust its near-term demand forecast for the Annual Assessment to account for extraordinary demand management measures that Metropolitan may intend or have already put into effect for the current year. Extraordinary demand management measures may include intensified communication and public outreach, and shortage allocations to its member agency customers through implementation of Metropolitan's WSAP. Non-extraordinary water savings from regular conservation and community outreach activities are considered part of Metropolitan's baseline demands and are not counted again for assessments of unconstrained demand.

Water Conditions for Current Year Available Supply Considering Current Year Conditions and One Dry Year

CWC Section 10632(a)(2)(B)(ii) requires the Annual Assessment to determine *"current year available supply, considering hydrological and regulatory conditions in the current year and one dry year."* The Annual Assessment will include two separate estimates of Metropolitan's annual water supply and unconstrained demand using: 1) current year conditions, and 2) assumed dry year conditions. Accordingly, the Annual Assessment's shortage analysis will present separate sets of findings for the current year and dry year scenarios. The CWC does not specify the characteristics of a dry year, allowing discretion to the Supplier. Metropolitan will use this discretion to refine and update its assumptions for a dry year scenario in each Annual Assessment as information becomes available.

In the 2020 UWMP, the "single dry year" is characterized to resemble conditions as a year in which conditions reflect the lowest water supply available to the Supplier. Metropolitan developed estimates of future demands and supplies from local sources and from Metropolitan sources based on 96 years (1922-2017) of historic hydrologic conditions. Supply and demand analyses for the single-dry year case was based on conditions affecting the SWP as this supply availability fluctuates the most among Metropolitan's sources of supply. Based on the 96-year period, 1977 was the single driest year for SWP supplies to Metropolitan. In addition, staff analysis of the 8-river index indicated that 1977 was the single driest year from 1922 through 2017. The 8-river index is used by DWR and other water agencies as an estimate of the unimpaired runoff (or natural water production) of the Sacramento and San Joaquin River basins, which are sources of water for the SWP.

Infrastructure Considerations

The Annual Assessment will consider any infrastructure issues that may pertain to near-term water supply reliability, including repairs, construction, and environmental mitigation measures that may temporarily constrain capabilities, as well as any new projects that may add to system capacity.

Metropolitan operates a distribution system that is flexible and adaptable allowing delivery of supplies from a combination of SWP, Colorado River, and regional storage sources to meet demands throughout its service area, as shown in Figure A.4-2. System distribution capabilities and limitations can add complexity to near-term reliability. For example, a portion of Metropolitan's service area currently cannot be served by Colorado River supplies. In the event of very low SWP supplies and available storage along the SWP system, Metropolitan's operations may be acutely challenged to meet SWP-only demands even though in that same year total supplies including Colorado River supplies may exceed total demands.

Metropolitan also has five regional water treatment plants, with capacities presented in Table A.4-4. Portions of Metropolitan's service area may receive water treated by one or a combination of several of these water treatment plants. Over the last 40 years, Metropolitan effectively delivered to its member agencies water supplies to meet demands ranging from 1.2 MAF per year to over 2.5 MAF per year.

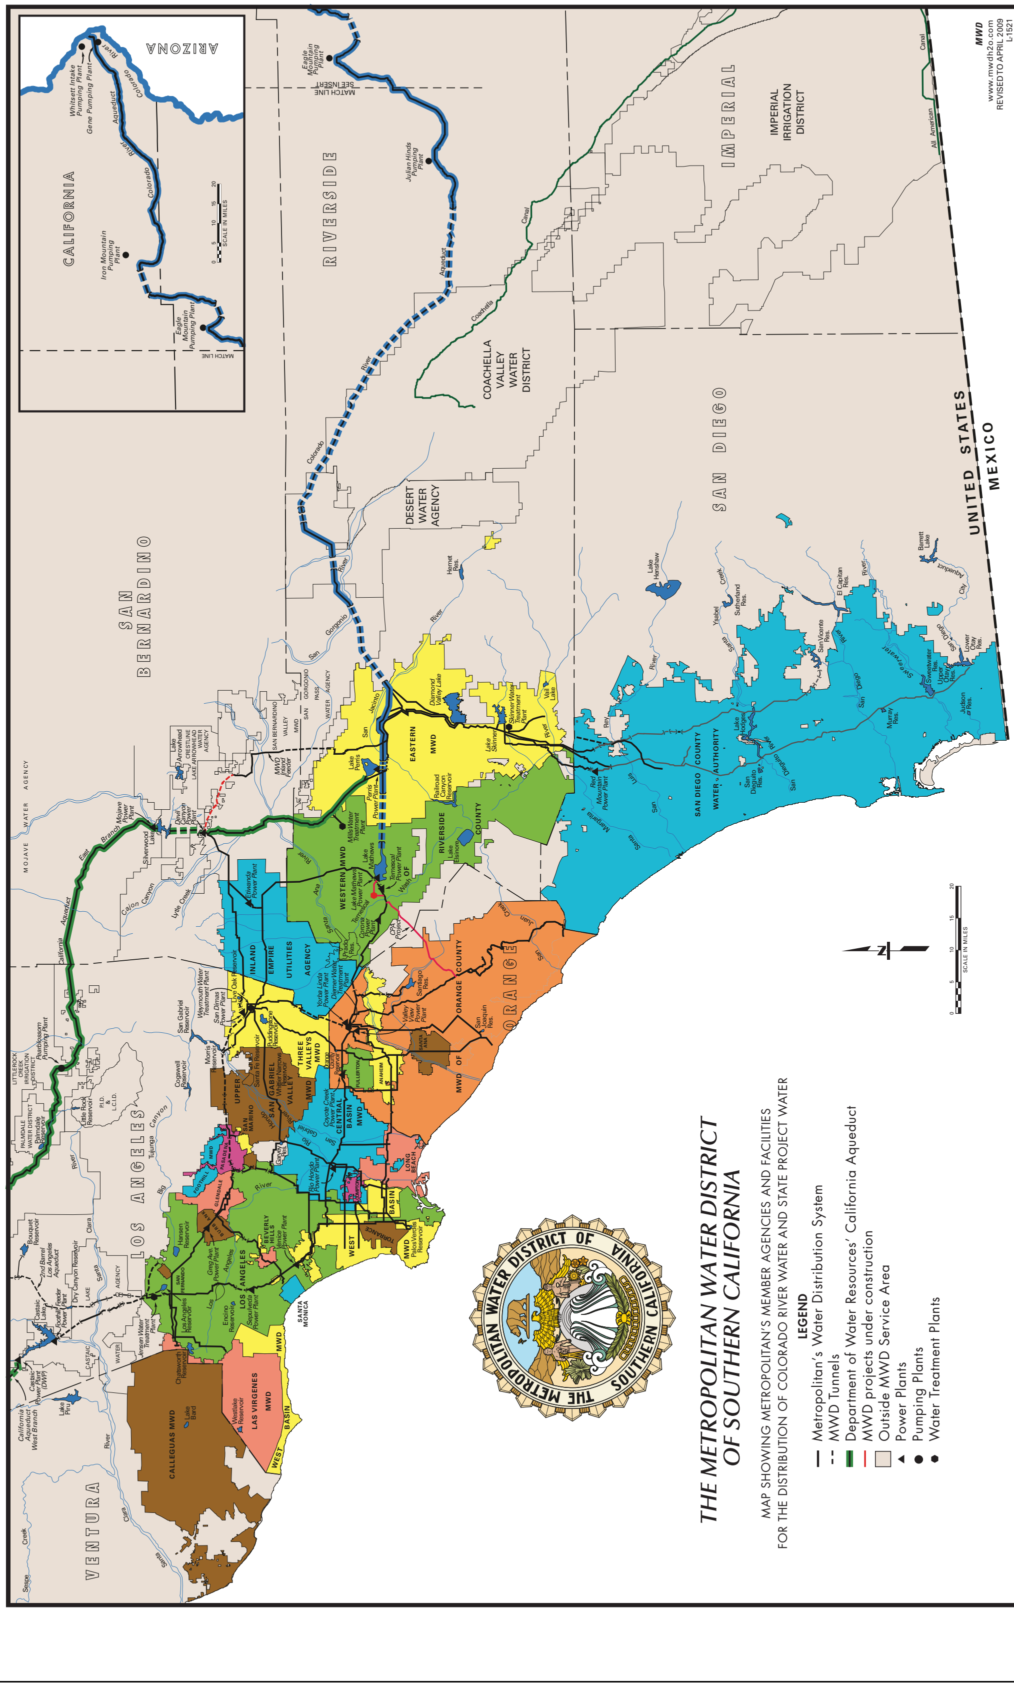
Table A.4-4
Metropolitan's Water Treatment Plants

Water Treatment Plant	Capacity (in MGD)
Jensen	750
Weymouth	520
Diemer	520
Mills	220
Skinner	350

Note: Rated capacity. Effluent capacities may be less to account for backwash.

Metropolitan and its member agencies continue to implement system improvements and modifications to effectively increase system flexibility during both normal operations when imported supplies are available and during extraordinary times when SWP supplies are reduced to maximize the use of more readily available Colorado River water and Diamond Valley Lake supplies.

Figure A.4-2
Metropolitan's Service Area



Throughout each year, Metropolitan regularly carries out preventive and corrective maintenance of its facilities. Metropolitan plans and performs shutdowns to inspect and repair pipelines and facilities and support capital improvement projects. These shutdowns involve a high level of planning and coordination within Metropolitan, as well as with member agencies, other affected organizations, contractors, and the community. These shutdowns are scheduled to ensure that major portions of the distribution system are not out of service at the same time. Operational flexibility within Metropolitan's system and the cooperation of member agencies allow shutdowns to be successfully completed while continuing to meet all system demands.

Metropolitan's Infrastructure Reliability Strategy helps to ensure long-term reliable performance of the system in an efficient and cost-effective manner. Infrastructure reliability is addressed through three programs: the Maintenance Management Program, the Infrastructure Protection Plan, and the Dam Safety Program. The activities performed under these programs allow for Metropolitan to extend the life span of its facilities and equipment and improve the overall reliability of the entire conveyance, treatment, and distribution system. In addition, seismic resiliency issues are addressed in the Seismic Risk Assessment and Mitigation Plan, which is included in Appendix 8 to the 2020 UWMP and incorporated herein by reference.

In the event that Metropolitan anticipates that an infrastructure issue is likely to impede or expand Metropolitan's capability to convey, treat, or distribute water during the current year, then the issue would be documented, and the determination of water reliability in the Annual Assessment would be adjusted accordingly.

Other Factors

Water quality is of paramount importance to water supply reliability. Metropolitan owns and operates five water treatment plants. Metropolitan is a national leader in providing safe drinking water that meets increasingly stringent standards, testing for over 400 constituents and performing nearly 200,000 water quality tests annually on samples gathered throughout its distribution system. Metropolitan's Water Quality Laboratory analyzes these samples to ensure that Metropolitan's delivered water meets or surpasses all state and federal drinking water standards. Because treatment to remove specific contaminants can be more costly than measures to protect water at the source, Metropolitan also actively supports improved watershed protection programs for its source waters in the Colorado River and SWP. For the Annual Assessment, any known issues related to water quality will be considered for their potential effects on water supply reliability.

A.4.4. Shortage Levels and Shortage Response Actions

Six Standard Water Shortage Levels

As required by California Water Code Section 10632(a)(3)(A), the WSCP is framed around six standard water shortage levels that correspond to progressive ranges of up to 10, 20, 30, 40, and 50 percent shortages and greater than 50 percent shortages. As shown in Table A.4-5, each of the six shortage levels represents an increasing gap between Metropolitan's estimated core supplies and unconstrained demand as determined in the Annual Assessment. As explained above, shortage percentages will be calculated by dividing the difference between core supplies and unconstrained demand by unconstrained demand. This calculation will be performed separately for anticipated current year conditions and for assumed dry year conditions. Shortage levels also apply to catastrophic interruption of water supplies, including, but not limited to, a regional power outage, an earthquake, and other emergency events. The shortage levels are defined in terms of the percent shortfall of supplies against demands.

Shortage Response Actions

California Water Code Section 10632(a)(4) requires the WSCP to specify shortage response actions that align with the defined shortage levels, and include, at a minimum, all of the following:

- Locally appropriate supply augmentation actions
- Locally appropriate demand reduction actions to adequately respond to shortages
- Locally appropriate operational changes
- Additional, mandatory prohibitions against specific water use practices that are in addition to state-mandated prohibitions and appropriate to the local conditions (Not applicable to Metropolitan)
- An estimate of the extent to which the gap between supplies and demand will be reduced by implementation of each action.

As indicated in Table A.4-5, shortage responses will be customized to meet the circumstances for the particular shortage. Because circumstances can change at any time, Metropolitan's shortage responses actions will be adjusted accordingly throughout the year. To determine specific actions that would be taken at each standard shortage level, Metropolitan will evaluate conditions specific to cost, timing, distribution needs and capabilities, and other variables that include SWP allocation, Colorado River conditions, demand reduction measures, supply program take capacities, and storage balances.

Shortages are characterized not merely by shortfalls in annual core water supplies, but also by the water balances in Metropolitan's storage programs. Thus, a 10 percent shortfall in core supplies could be met entirely with stored water if storage levels are high. If storage levels are already depleted, the same shortfall in core supplies could potentially require a more complex mix of supply augmentation and demand reduction actions. In the most severe situations, allocating shortages to member agencies through the WSAP would address any remaining shortages not already mitigated by supply augmentation and lesser demand reduction actions.

Metropolitan has invested extensively in a diverse portfolio of supply sources and system resiliency to prepare for a wide range of possible challenging conditions. Metropolitan follows the principles of its WSDM Plan, which was adopted in 1999 and provides policy guidance for managing regional water supplies to achieve reliability. It identifies a broad sequence of actions during surpluses and shortages to minimize probability of severe shortages, based on detailed modeling of Metropolitan's existing and expected resource mix. The WSDM Plan recognizes the link between surplus and shortages and integrates planned operational actions with respect to both conditions. The WSDM Plan is included as Attachment A to this document.

Table A.4-5
Shortage Stages and Response Actions

Shortage Stage	Shortage Percentage	Shortage Response	
1	Up to 10%	Take from Storage Execute Flexible Supplies Implement Voluntary Demand Reduction Implement Water Supply Allocation Plan	• 0 to 100% met by Storage • 0 to 100% met by Flexible Supplies • 0 to 20% of total retail water use met by implementing Communication Plan • 0 to 50% of total base demand met by WSAP supply allocation
2	10% to 20%	Take from Storage Execute Flexible Supplies Implement Voluntary Demand Reduction Implement Water Supply Allocation Plan	• 0 to 100% met by Storage • 0 to 100% met by Flexible Supplies • 0 to 20% of total retail water use met by implementing Communication Plan • 0 to 50% of total base demand met by WSAP supply allocation
3	20% to 30%	Take from Storage Execute Flexible Supplies Implement Voluntary Demand Reduction Implement Water Supply Allocation Plan	• 0 to 100% met by Storage • 0 to 100% met by Flexible Supplies • 0 to 20% of total retail water use met by implementing Communication Plan • 0 to 50% of total base demand met by WSAP supply allocation
4	30% to 40%	Take from Storage Execute Flexible Supplies Implement Voluntary Demand Reduction Implement Water Supply Allocation Plan	• 0 to 100% met by Storage • 0 to 100% met by Flexible Supplies • 0 to 20% of total retail water use met by implementing Communication Plan • 0 to 50% of total base demand met by WSAP supply allocation
5	40% to 50%	Take from Storage Execute Flexible Supplies Implement Voluntary Demand Reduction Implement Water Supply Allocation Plan	• 0 to 100% met by Storage • 0 to 100% met by Flexible Supplies • 0 to 20% of total retail water use met by implementing Communication Plan • 0 to 50% of total base demand met by WSAP supply allocation
6	More than 50%	Take from Storage Execute Flexible Supplies Implement Voluntary Demand Reduction Implement Water Supply Allocation Plan Take from Emergency Storage, if needed	• 0 to 100% met by Storage • 0 to 100% met by Flexible Supplies • 0 to 20% of total retail water use met by implementing Communication Plan • 0 to 50% of total base demand met by WSAP supply allocation • Take from emergency storage during a catastrophic event

Supply Augmentation Actions

Generally, Metropolitan's first response to any gap between core supplies and demand is to make optimal use of its supply augmentation options consisting of draws from flexible supply programs and storage reserves listed in Table A.4-6. To supplement its core water supplies from the SWP and Colorado River, Metropolitan has developed and actively manages a portfolio of water supply programs, including water transfer, storage and exchange agreements, the supplies created by which are conveyed through available CRA capacity or the California Aqueduct. Metropolitan pursues voluntary water transfer and exchange programs with other entities to help mitigate supply/demand imbalances and provide additional dry-year supply sources. Metropolitan has also developed significant storage capacity in reservoirs and groundwater banking programs both within and outside of the Southern California region. In a hypothetical single dry year assessment within the 2020 Urban Water Management Plan, Metropolitan could take up to approximately 1.8 MAF in a single year to meet dry year demands. Actual take capabilities would depend on various factors including water balances, location, and operational constraints.

Flexible Supplies

Metropolitan can augment its core Colorado River supplies through agreements with other agencies that have rights to use such water. Metropolitan determines the delivery schedule of these supplies throughout the year based on changes in the availability of SWP and to a smaller extent the higher priority water use adjustment for Colorado River water.

In addition to the basic SWP contract provisions, Metropolitan has other contract rights that facilitate augmentation of its SWP supply. Each SWP contractor has the right to use the facilities to move water supplies associated with agreements, water transfers, and water exchanges at the incremental cost. Metropolitan utilizes this ability in conveying water obtained through a number of agreements and exchanges with agencies in California's Central Valley north of the Bay-Delta and southward to Southern California.

Storage

A key component of Metropolitan's water supply capability is the amount of water in Metropolitan's storage facilities and programs in which surplus amounts of water in normal and wet years are captured until needed to augment core supplies. Metropolitan has developed an extensive storage portfolio made up of units within and outside Metropolitan's service area that includes both dry-year and emergency storage capacity. Such units, totaling approximately 6.0 MAF, include reservoirs, conjunctive use and other groundwater storage programs within the service area, and groundwater and surface storage accounts outside the service area delivered through the CRA or SWP. Consistent with the Emergency Storage Objective that was revised in 2019, approximately 750,000 AF of total stored water is emergency storage reserved for use in the event of supply interruptions from earthquakes or similar emergencies.

Table A.4-6
Supply Augmentation Actions: Flexible Supplies and Storage

Source	Flexible Supplies	Storage
Colorado River		Lake Mead Intentionally Created Surplus (ICS) Storage Program Southern Nevada Water Agency Storage and Interstate Release Agreement Desert Water Agency/Coachella Valley Water District Advanced Delivery Account Imperial Irrigation District Storage
State Water Project	SWP Transfers: State Water Contractors Buyers Group SWP Transfers: Yuba Accord Dry-Year Purchase San Bernardino Valley Municipal Water District Program	SWP Carryover DWR Flexible Storage (Castaic Lake and Lake Perris) SWP Banking Programs
In-Region		Diamond Valley Lake Lake Mathews Lake Skinner Conjunctive Use Programs (CUP)

Demand Reduction Actions

Demand reduction actions are extraordinary measures taken to temporarily constrain water demand during a shortage. For the purpose of the WSCP and the Annual Assessment, it is important to separate temporary reductions in demand from baseline conservation as they relate to constrained and unconstrained demands. WSCP demand reduction actions result in constrained demands. Water savings from WSCP demand reduction actions must be factored into estimates of unconstrained demands for Annual Assessment shortage determinations. Intensity of demand reduction measures will vary by the severity of shortage and availability of other cost-effective supply augmentation measures. Early demand reduction actions tend to be voluntary measures that are comprised of outreach and education actions from Metropolitan's WSCP Communication Plan (see following section A.4.5). More severe conditions may necessitate supply allocations to wholesale customers through implementation of the WSAP. Table A.4-7 shows the demand reduction measures available to Metropolitan.

Table A.4-7
Demand Reduction Actions

	Demand Reduction Actions
Voluntary Measures	Implement Communication Plan (May apply to Shortage Levels 1-6, Crisis) • Public information campaigns • Community outreach and media relations • Public opinion research • Interagency and intergovernmental coordination
Mandatory Measures	Implement Water Supply Allocation Plan (May apply to Shortage Levels 1-6, Crisis)

Benefits of public information campaigns include rapid implementation and raising public awareness of the severity of the water shortage. For this reason, public information campaigns are included as a Demand Reduction Action in the WSCP. According to the American Water Works Association, water savings from this measure alone range from 5 to 20 percent, depending on the time, money, and effort spent.[2] If public outreach targets between 5 and 10 percent of population, then demand would be assumed to be reduced by 5 to 20 percent of the 5 to 10 percent. The size of media campaign is correlated with the number of people being reached.

Implement Communications Plan

Metropolitan's WSCP Communication Plan details Metropolitan's action-oriented strategy for education, outreach, and coordination during each WSCP standard shortage stage and in response to a catastrophic loss of supply. See the following section A.4.5 for the WSCP Communications Plan.

Enhanced Conservation Program

Although not considered as a WSCP demand reduction action because of their limited effect in the immediate term, Metropolitan administers regional conservation programs and co-funds member agency conservation programs designed to achieve greater water use efficiency in residential, commercial, industrial, institutional, and landscape uses. Metropolitan may implement extraordinary measures to temporarily enhance conservation during a shortage which include, but are not limited to, increasing rebates, reducing program eligibility requirements, working with rebate vendors to create in-store marketing and direct outreach to businesses, increasing direct install efforts with member agencies and partners, and working with water retailers and retail customers to develop onsite leak prevention programs. While the savings from conservation programs may not be realized quickly enough to mitigate the need for other shortage response actions, water-efficient device retrofit rebates, landscape conversions, and leak prevention all contribute to ongoing structural water savings. Conservation device retrofits help to recover storage in future years by lowering demands in all years, not only shortage years.

[2] American Water Works Association. 2019. Manual of Water Supply Practices – M60, Second Edition: Drought Preparedness and Response. p. 35

Water Supply Allocation Plan

Under most conditions, Metropolitan can meet all of its service area's wholesale water needs. However, during severe water shortage situations when pubic information campaigns and enhanced conservation programs are insufficient to generate the needed demand reduction, Metropolitan may find it necessary to temporarily limit and allocate supplies to its member agencies. Metropolitan's WSAP allocates Metropolitan's water supplies among its member agencies, based on the principles contained in the WSDM Plan, to mitigate drawdowns from water storage reserves. The WSAP was originally approved by Metropolitan's Board in February 2008 and has been implemented three times since its adoption, most recently in April 2015. The WSAP provides a formula for equitable distribution of limited water supplies. If needed, a WSAP action is typically approved in the month of April with implementation beginning in the following July. This allows Metropolitan's member agencies time to prepare and to adjust their estimates for Metropolitan current year supply for their own WSCP Annual Assessments.

The WSAP allocation is a costly shortage response action that places acute burdens upon member agencies and the public. Other shortage response actions are generally preferred to the extent practicable. Metropolitan's overall strategy considers WSAP allocations to be a fallback option to address any remaining shortages when supply augmentation actions and other demand management measures are insufficient to meet demand reduction objectives. For reference, the WSAP is included as Attachment B to this document.

Operational Changes

During shortage conditions, operations may be affected by supply augmentation or demand reduction responses. For example, Metropolitan may temporarily alter maintenance cycles, defer planned system outages, and adjust the flow and routing of water through its system to more effectively distribute available supply across the service area, including areas that are currently only able to be served by SWP water supplies.

Because of the extensive and complex nature of Metropolitan's conveyance and distribution system, and the varying levels of local supplies available among each of the member agencies, by necessity, any supply-related shortage response actions triggered under the WSCP would be carefully chosen to optimally match available resources with specific localized demands by the member agencies.

Metropolitan's diversified portfolio of water supplies presents operational opportunities and challenges during droughts. Because water resources available to the Metropolitan service area come from three geographically distinct regions—Northern California, the Colorado River, and local resources—a relatively dry year affecting one of these three regions can be offset by relatively abundant supplies from the other two regions. For example, a year of ample precipitation within Metropolitan's service area tends to depress demand and enhances local water resources, further reducing demands on imported supplies. A wet year in the Sacramento-San Joaquin watersheds increases the SWP allocation, facilitating reduced diversions from the Colorado River in favor of storing supplies in Lake Mead or in the Desert Water Agency/Coachella Valley Water District Advanced Delivery Account. Conversely, a shortfall on the SWP may require system operational modifications to maximize Colorado River diversions and the delivery of Colorado River supplies to areas normally served with SWP supplies. Metropolitan's Colorado River core supplies are relatively stable from year to year and are less subject to severe supply reductions.

Additional Mandatory Prohibitions (not applicable)

California Water Code Section 10632(a)(4)(D) calls for "additional, mandatory prohibitions against specific water use practices that are in addition to state-mandated prohibitions and appropriate to the local conditions" to be included among the WSCP's shortage response actions. However, this item is not applicable to Metropolitan. As a regional wholesaler, Metropolitan does not dictate or control the end uses of water by retail consumers.

Shortage Response Action Effectiveness

As shown in Table A.4-5, WSCP shortage response actions will be implemented to reflect the overall conditions facing Metropolitan and the resources available in that given year. Supply augmentation actions consisting of stored water and as-needed flexible supplies are expected to address between 0 to 100 percent of anticipated shortages for any shortage stage, depending on availability of those supplies; in lesser WSCP shortage stages, it is likely that shortages can be completely addressed through supply augmentation.

Efficacy of demand reduction efforts is difficult to estimate or predict, but water savings are a function of the extent to which public information campaigns reach water users and the degree of consumer response to those messages. Given the estimate of between 5 to 20 percent effectiveness described above, in concept, up to 20 percent of retail demands could be reduced if a successful media campaign reached and influenced the entire service area population. Consistent with the WSCP Communications Plan in the following section A.4.5, anticipated shortages will involve an appropriately-sized outreach campaign to address the targeted demand reduction, which depends on the combined effectiveness of other shortage response actions.

As shown in Table A.4-8 below, the WSAP is designed to reduce demands by up to approximately 50 percent of the WSAP's calculated base demand. The WSAP contains 10 levels of allocation, and each level is approximated to generate an additional 5 percent reduction from base demands. Table A.4-8 gives examples of estimated savings by each WSAP level using a hypothetical base demand of 1.8 MAF. Actual reductions and base demands are based on a formula that includes various factors such as actual local supply production, population growth, and conservation. The WSAP is expected to address any remaining shortage not met by other shortage response actions.

Table A.4-8
Water Supply Allocation Plan Levels

WSAP Level	Approximate Percent Reduction	Example Base Demand	Estimated Demand Reduction
1	5%	1.8 MAF	90,000 AF
2	10%		180,000 AF
3	15%		270,000 AF
4	20%		360,000 AF
5	25%		450,000 AF
6	30%		540,000 AF
7	35%		630,000 AF
8	40%		720,000 AF
9	45%		810,000 AF
10	50%		900,000 AF

Catastrophic Interruption of Water Supplies

Metropolitan's Emergency Storage Objective is a planning estimate that represents the amount of water that Metropolitan would hold in storage for the region in preparation for a catastrophic earthquake that would damage the aqueducts that transport imported water supplies to Southern California, including: the Colorado River Aqueduct, both the East and West branches of the California Aqueduct, and the Los Angeles Aqueduct. Emergency storage allows Metropolitan to deliver reserve supplies to the member agencies to supplement local production. This helps avoid severe water shortages during periods when the imported water aqueducts may be out of service.

The Emergency Storage Objective considers a six- and twelve-month outage period for the imported supply aqueducts incorporating latest seismic information and operational flexibility of Metropolitan's system, a retail water demand cutback ranging from 25 to 35 percent considering the level of conservation that the region achieved during the recent drought, and an aggregated loss of 10 to 20 percent of local supplies accounting for factors that could affect local production during emergency conditions.

In 2019, Metropolitan and its member agencies completed a process to update the Emergency Storage Objective, which was set at 750,000 AF. This level of storage would prevent severe water shortages to the region given new information on expected recovery durations. The emergency storage volume represents a planning estimate for how much water Metropolitan would store for the region in preparation for a catastrophic earthquake or other disaster. It is not intended to set a basis or a policy for allocating or apportioning storage for any individual member agency.

As an additional tool, in July 2019, the Board adopted amendments to Metropolitan's Administrative Code enabling deliveries of member agency water supplies in Metropolitan's system in an emergency. These deliveries are intended to provide Metropolitan's member agencies the ability to deliver member agency water through Metropolitan's system under specific emergency conditions. Emergency deliveries can only be made if Metropolitan is unable to make deliveries to a member agency due to physical damage to Metropolitan's system resulting from a natural disaster or other emergency, and there are no alternate means for Metropolitan or the member agency to provide service to an area without the use of a portion of Metropolitan's system.

Metropolitan's strategy for catastrophic water shortage conditions is further discussed in Appendix 8 to the 2020 UWMP and incorporated herein by reference.

Emergency Freshwater Pathway (Sacramento-San Joaquin Delta)

DWR has estimated that in the event of a major earthquake in or near the Delta, water supplies could be interrupted for up to three years, posing a significant and unacceptable risk to the California business economy. A post-event strategy would provide necessary water supply protections to avert this catastrophe. Such a plan has been coordinated through DWR, the Army Corps of Engineers, USBR, California Office of Emergency Services, Metropolitan, and the State Water Contractors. Additional information on the creation of an emergency freshwater pathway and other actions in the Delta is included in Section 2.5 of the 2020 UWMP and incorporated herein by reference.

Emergency Response Plans

Metropolitan also has two Emergency Response Plans: one dated March 2019 that has been in place long-term and is updated periodically; and a second dated September 2020, prepared pursuant to the requirements of the recently-enacted America's Water Infrastructure Act of 2018. The two plans work in conjunction. Together, Metropolitan's Emergency Response Plans present Metropolitan's organization and strategy for response to emergencies caused by natural hazards, malevolent acts, or other unavoidable circumstances. Metropolitan operates in accordance with the California Standardized Emergency Management System, the Incident Command System, and the National Incident Management System. The Emergency Response Plans provide guidelines for evaluating an emergency situation, responding to an emergency, and activating Incident Command Posts and the Emergency Operations Center. They also describe the Emergency Response Organization. Although the plans provide a framework for emergency response, they do not attempt to identify and discuss every potential situation or problem that may occur during an emergency. The plans will be exercised and updated regularly.

Seismic Risk Assessment and Mitigation Plan

Although the magnitude of damages resulting from a significant seismic event are impossible to predict, Metropolitan's water conveyance and distribution facilities are designed either to withstand a maximum probable seismic event or to minimize the potential repair time in the event of damage. Metropolitan's holistic strategy for seismic resilience follows a "defense in depth" multi-layered approach for managing risk. Metropolitan's Seismic Resilience Strategy has three primary objectives:

1. Provide a diversified water supply portfolio, system flexibility, and emergency storage
2. Prevent damage to water delivery infrastructure in probable seismic events and limit damage in extreme events
3. Minimize water delivery interruptions through a dedicated emergency response and recovery organization

Beginning January 2020, CWC Section 10632.5 mandates urban water suppliers to include in their UWMPs a seismic risk assessment and mitigation plan to assess the vulnerability of each of the various facilities of a water system and mitigate those vulnerabilities. For Metropolitan, the required seismic risk assessment and mitigation plan is part of its resilience strategy and is included in Metropolitan's 2020 UWMP Appendix 9: Seismic Risk Assessment and Mitigation Plan and incorporated herein by reference.

A.4.5. WSCP Communications Plan

Introduction

Following the record-breaking drought of 2012-2016, Metropolitan concentrated on building on its conservation and education outreach programs to emphasize water efficiency as a sustainable way of life, rather than solely a response to dry conditions or drought. Messaging has encouraged behavioral changes that can be sustained regardless of weather and uses tools and technology that can be implemented to permanently save water in homes and businesses, particularly outdoors where up to 70% of total water use occurs. These efforts have helped solidify a conservation ethic across Southern California, supporting a $1.5 billion investment in conservation, recycling and groundwater recovery since 1990. When combined with additional investments in storage, local supply development and programs to increase water storage reserves in wet years, the region is well positioned to withstand future droughts. Still, in response to the challenges of climate change and other abnormal supply conditions, increased water efficiency will still be necessary. And as those conditions become more prevalent, effective communication strategies and a common understanding of necessary actions between water agencies, the public, elected officials and other key stakeholders become even more important should the district need to activate the WSCP. These relationships and communication tools must be well-established to be successful. To that end, water providers should aim to communicate to customers in the following areas:[3]

1. Steps customers should take to plan for and protect themselves in emergency situations, ranging from abnormal to catastrophic water supply conditions
2. Actions water providers are taking to plan for and respond to these emergency situations
3. Efforts to invest and maintain critical water infrastructure
4. Steps water providers are taking to prepare for and respond to emergency situations that could impact water supplies – from drought to natural disasters

Several factors influence the communication strategies needed to address the diverse characteristics of Metropolitan's 5,200 square-mile service area, particularly when there is an urgent need for conservation. As a wholesaler serving 26 member agencies and a diverse region that is home to 19 million people, no single communication message or strategy connects with everyone in the region. Furthermore, state and local water regulations during periods of drought or supply shortages can result in a broad range of water-saving requirements and goals across the region. Qualitative research from previous droughts has also provided valuable insight on attitudes and behaviors toward water conservation, including drought fatigue, water quality concerns, increasing water rates and equity issues. These factors, though inherently complex, are conducive to collaboration that elevates the importance of drought resiliency. This section of the WSCP describes the basic communications strategies needed to help Metropolitan effectively communicate vital information for each of the six standard water shortage levels that represent changes from normal reliability. The six standard water shortage levels depicted in this communications plan correspond to:

- Progressively increasing estimated shortage conditions: up to 10, 20, 30, 40, 50, and greater than 50% shortage compared to the normal reliability conditions

[3] Source: 2019 Statewide Survey of Residential Customers Covering Water

Collaboration

Collaboration with its member agencies is central to Metropolitan's outreach plans during drought, water shortages or other demand management periods. Developing and delivering a concise regional message in multiple languages is made possible through consistent coordination with member agencies and their constituents. Metropolitan's External Affairs group regularly engages and interacts with member agency staff in several capacities, including but not limited to the following groups:

- Member agency managers
- Legislative and government affairs representatives
- Water use efficiency/conservation coordinators
- Public information officers
- Education coordinators

In addition to member agency coordination, Metropolitan interacts with agencies and organizations outside of the region, including:

- Department of Water Resources
- State Water Resources Control Board
- Association of California Water Agencies
- California Municipal Utilities Association
- Colorado River Water Users Association
- California Water Efficiency Partnership
- Alliance for Water Efficiency
- Other state and federal agencies

As seen in past droughts, the methods of communication within these groups and the frequency of meetings fluctuate based on the changing needs of our member agencies and their key audiences. Water shortage conditions are ever-evolving, therefore remaining flexible yet focused not only reduces the risk of discordance, it also ensures key audiences throughout Southern California receive timely, valuable and cohesive information.

As mentioned, Metropolitan's WSCP includes six levels of potential shortage. The water-savings actions associated with each level of shortage will vary greatly, and Metropolitan recognizes the many different approaches to properly respond to each WSCP level. This section provides a general description of messaging strategies that would be implemented at each level, leading up to more focused crisis communication strategies. The plans need to be adaptable and cannot offer one-size-fits-all approaches. Metropolitan management and/or Board of Directors could also call for specific messaging strategies that address unique shortage scenarios.

Key Audiences

Communicating to various stakeholders is essential during normal supply periods and becomes increasingly more involved during water shortages. Below is a list of key audiences:

- Member agencies and their customers
- General public

- State, federal and local elected officials and their district office staff
- Homeowners and renters
- Multi-family property owners/managers/landlords
- Business associations/chambers of commerce
- Commercial-industrial property owners/managers
- Landscape contractors/suppliers
- Restaurant/hotel industries
- School districts/educators/students
- Building and construction trade associations
- Community/civic leaders
- Land-use agencies
- Environmental groups
- Community-based and non-profit organizations
- Non-English-speaking populations
- Disadvantaged/under-invested communities

Communicating to these audiences requires varying levels of involvement depending on the status of supply conditions. Feedback, research, and leveraging existing relationships are central to an effective communications plan; therefore, External Affairs and Water Resource Management staff will continue to coordinate closely with member agencies, stakeholders, and governing agencies on an ongoing basis to ensure appropriate messaging is culturally competent and provided in multiple languages to reflect the region's demographics.

Goals and Objectives

Metropolitan's communications goals are rooted in the following guiding principles:

- Motivate key audiences to:
    - Increase conservation
    - Follow voluntary or mandatory water use guidelines
    - Participate in water-saving incentive programs
    - Encourage family, friends, neighbors and colleagues to do all the above
- Raise awareness about:
    - Water shortage and/or drought conditions
    - Water sources, supplies and reserves
    - Local, regional and state regulations
- Educate key audiences about:
    - Water supply reliability
    - Water infrastructure and delivery
    - Water quality

- Prepare the region for:
  - Varying water supply conditions
  - Escalating supply shortage levels

Standard Communication

Conservation as a way of life remains central to messaging during normal supply conditions. Regional rebate programs, indoor and outdoor water use efficiency, investments to maintain infrastructure, emergency preparedness, local supply programs, water quality, and regional supply reliability are among some of the themes that make up a normal supply period's communications mix to encourage ongoing conservation actions. Below is a snapshot of the various strategies involved:

- Media relations (news releases and advisories, interviews, op-eds)
- Social media (Twitter, Instagram, Facebook, YouTube, LinkedIn)
- Websites and Blogs
  - mwdh2o.com
  - bewaterwise.com
  - socalwatersmart.com
- Digital, print and other paid media marketing
- Search engine optimization
- E-newsletters
- Community events
- Education outreach
- Business outreach

Level 1 Communications – up to 10% Shortage

This section addresses communications strategies Metropolitan uses during periods of 10% water shortage conditions. In addition to the district's ongoing communications efforts, a 10% shortage would require the following elements:

- Media relations and communications
  - Maintain media relations activities with enhanced communication about the specific need to conserve; provide media with regional water supply conditions and Metropolitan's shortage response action updates
    - Press releases, advisories, op-eds, direct outreach to media to drive earned media opportunities
    - Ethnic media outreach in multiple languages
  - Produce and distribute fact-based informational materials such as fact sheets, podcasts, and B-roll video
- Social media
  - Emphasize ways to conserve immediately (shorter showers, less watering, links to tools on bewaterwise.com, etc.), as well as continued promotion of conservation as a way

of life initiatives such as regional water use efficiency incentives and other rebate programs including the district's Turf Replacement Program

    - Paid social media boosting to target the district's entire service area

  - Encourage member agency co-branding and messaging continuity

    - Share social media creative with the public information officer working group and conservation coordinators

- Web

  - Establish a SharePoint site for member agency and public to download all water supply and conservation materials

  - Update all Metropolitan websites with pertinent conservation and water supply information and highlight such information

  - Provide links to local watering restrictions and conservation efforts

- Member agency coordination

  - Enhance collaboration and communication with member agencies to streamline messaging

  - Involve member agencies in development of a communications plan

  - Provide regular campaign updates to member agency managers, staff and board members.

  - Provide member agencies with campaign outreach materials (newsletter articles, creative design, bill inserts, etc.) for customization and distribution

- Community outreach

  - Make water supply conditions and conservation messaging a key component of all regular community outreach

  - Make additional, specialized outreach to inform non-profit organizations and civic/community leaders about water supply conditions and conservation efforts

    - Community events/webinars

    - Non-profit organization e-newsletters

- Education outreach

  - Update district curriculum to reflect the enhanced need to conserve and make water supply conditions and conservation messaging a key component of all regular education outreach

  - Communicate to K-12 school districts and colleges/universities about the need for increased conservation

  - Provide regional water and environmental education programs with materials addressing the need for increased conservation

- Legislative and government affairs

  - Coordinate with local, state and other elected officials in the region about the need to conserve

  - Encourage officials to promote these efforts to constituents

In addition:

- Work with member agencies to target key industries or groups to raise awareness about water-use efficiency programs and regional water supply conditions
  - o Restaurants
  - o Hotels/motels
  - o Public agencies
- Research and public opinion
  - o Conduct research to gain insights on public opinion, attitudes and beliefs toward conservation and water shortage levels
  - o Message testing with key audiences

Level 2 Communications – up to 20% Shortage

In a more severe supply shortage or demand management period, Metropolitan will continue actions outlined in Level 1 communications strategies, and add the following efforts, which are designed to address a 20% percent mandatory conservation under the WSCP:

- Media relations and communications
  - o Paid advertising – Execute a multimedia, multilingual regional advertising campaign to reflect a more urgent message emphasizing the need for compliance with mandatory water-use restrictions. Place paid advertisements in the following platforms:
    - ▪ Out of Home (billboards, bulletins, bus shelter ads)
    - ▪ Radio
    - ▪ Television
    - ▪ Digital
    - ▪ Grassroots
  - o Host press conference to discuss current water shortage conditions, shortage response actions, and outlook
  - o Coordinate with other regional or state agencies for greater impact and reach
- Social media
  - o Emphasize a clear and practical message conveying mandatory water-use restrictions, drought conditions and ways to save water
  - o Establish more targeted and focused social media advertising strategies – targeted boosting and messaging
- Member agency coordination
  - o Meet with member agencies to streamline a more urgent and serious campaign tone
  - o Coordinate paid media flights with member agencies to leverage regional exposure and distribution
  - o Provide multimedia and multilingual campaign materials for member agency customization

- Community outreach
  - Coordinate with community-based organizations and leaders with higher impact, reach and credibility
  - Inform, debrief and prepare community/civic leaders to become water conservation ambassadors in their respective communities
- Legislative and government affairs
  - Increase briefing activity with state and local officials on water supply conditions, shortage response actions, and water conservation advertising campaign

In addition:

- Help prepare and distribute materials about restrictions, ordinances and guidelines through stakeholder communication channels, including but not limited to:
  - Business organizations
  - Civic organizations
  - Elected officials
  - Building/plumbing/construction associations
  - Building managers
  - Landscape contractors
- Increase outreach efforts to key associations and interest groups throughout the region, emphasizing immediate conservation goals

Level 3 and 4 Communications – up to 30% or 40% Shortage

In addition to Level 2 communications strategies, the following efforts will address an even more severe shortage of 30%-40% mandatory conservation under the WSCP:

- Media relations and communications
  - Increase media relations activities, with an added emphasis on the severe regional water supply conditions, the shortage response actions triggered or expected to be triggered, and the mandatory need to conserve
  - Host news conference in multiple languages alongside high-level public officials to highlight severity and extreme measures needed
  - Continue the following with greater frequency and stronger, more critical messaging:
    - Paid advertising campaign
    - Press releases, advisories, op-eds, etc.
    - Direct media outreach offering pre-recorded radio and TV interviews
    - Ethnic media outreach in multiple languages
- Social media
  - Messaging shift to reflect severity of supply conditions and shortage response actions triggered or expected to be triggered– conservation is mandatory to maintain day-to-day activity and future supplies, quality of life now being impacted

- Web
  - Make conservation messaging front and center on all websites
- Community Outreach
  - Host a community leader briefing, bringing together representatives from community-based organizations from across the region to learn about the severity of water supply conditions
- Member agency coordination
  - Continue to streamline messaging about WSCP level escalation to ensure message continuity throughout the region
  - Help member agencies address local and mandatory conservation needs
  - Coordinate with member agencies on any updated messages and campaign activities emphasizing extreme actions that must be taken
- Legislative and government affairs
  - Outreach to legislative leadership at state and federal level to raise awareness at high levels

In addition:

- Specialized targeted outreach to:
  - Special interest groups
  - Public agencies
  - County and city departments
- Assess the goals and objectives of regional rebate programs, begin a shift toward immediate water-saving actions
- Research and public opinion
  - Conduct public opinion research studies including focus groups to determine attitudes and beliefs toward extreme conservation levels in order to effectively communicate severity of supply conditions and the mandatory need to conserve

Level 5-6 Communications – 50% Shortage or more

The severity of this level of the WSCP calls for immediate, extreme conservation measures and a focus on water use for health and safety only. As with previous levels, communications strategies at this level of the WSCP incorporate and build upon ongoing efforts.

Key Communications Strategies

- Consider establishing a Joint Information Center (JIC) to pool crisis communications among emergency responders and affected local, state and federal agencies
- Produce and distribute fact-based informational materials such as fact sheets, podcasts, and B-roll video
- Host a press conference to announce the severity of water shortage level and shortage response actions triggered or anticipated to be triggered, to be held in conjunction with regional and/or state emergency response and public health authorities

- Emphasize work being done by Metropolitan and its member agencies to alleviate the impacts of such a severe shortage
- Focus on the need for residential and commercial customers across the region to do their part to get through the crisis situation
- Offer vulnerable populations increased assistance, in coordination with regional emergency response teams
- Keep the media and key stakeholders informed with frequent supply condition reports
- Shift from traditional advertising campaign efforts to emergency and crisis communication approach
- Messaging is no longer conservation-focused, begin shift to crisis response communications protocols

Crisis Communications – Catastrophic Shortage

In the event of a catastrophic shortage due to an infrastructure failure and/or natural disaster, Metropolitan will enact its crisis communications plan in accordance with local, regional, state and federal emergency response guidelines that ensure a coordinated effort and effective response. This plan utilizes the Standard Emergency Management System, the Incident Command System and the National Incident Management System.

Strategic Message Development

- In an emergency, communications messages will be created in a complex environment in which the tensions of multidirectional information flows must be balanced with the need for strategic message development

Message Dissemination

Communication efforts will center on the core identified tasks: providing information to the public and external audiences. Information dissemination tools:

- Website (mwdh2o.com, bewaterwise.com)
- Social Media (Twitter, Facebook, Instagram, YouTube)
- MetAlert Emergency Notification System + RSS Feeds
- Press Releases and statements
- Participation in joint information centers

Information Dissemination

- Public Information
    - o Activate and manage the mechanisms for responding to public requests for information via social media, telephone, in writing, or by e-mail
    - o Prepare Metropolitan's telephone operators for responding to and monitoring calls related to emergency incidents; brief them and provide scripts on how to respond to questions and where to direct calls for other requests
    - o Work with subject matter experts to create situation-specific fact sheets, Q&A documents and updates
    - o Respond to requests and inquiries from special interest groups

  - Oversee and manage Metropolitan's emergency response website if needed, in addition to mwdh2o.com, social media, telephone, and public email correspondence response systems; establish and maintain links to other emergency response websites
  - Manage the development and testing of messages and materials for cultural and language requirements of special populations
  - Post updates on social media channels. Monitor and respond to comments as needed/appropriate
- Member agencies, partnering agencies and elected/legislative officials:
  - The Public Information Officer (PIO) or Crisis Communications Team will communicate, as needed, with the PIOs for member agencies and other partnering agencies
  - Help organize and facilitate official meetings and briefings to provide information and receive input from member agencies, other partners or stakeholders
  - Notify legislative/elected officials as needed

A.4.6. Legal Authorities

This section describes the legal authorities that empower Metropolitan to implement and enforce its shortage response actions. Metropolitan is a wholesale water provider organized as a cooperative of 26 voluntary members. Metropolitan was formed pursuant to the Metropolitan Water District Act, Statutes 1969, chapter 209, codified at California Water Code, Appendix Section 109 (the "MWD Act"). Pursuant to the MWD Act, Metropolitan has the express and implied statutory authority to "[p]rovide, sell, and deliver water at wholesale for municipal and domestic uses and purposes," among other powers. (MWD Act, §§ 120, 130.) To accomplish the provision of water, Metropolitan is also expressly authorized to promote and implement conservation programs, including during times of water shortage. (MWD Act, § 130.5.)

Metropolitan also has authority under the California Water Code to implement supply shortage programs. (Cal. Water Code, §§ 350-359, 375-378.) For example, Section 375(a) of the Water Code provides:

> *Notwithstanding any other provision of the law, any public entity which supplies water at retail or wholesale for the benefit of persons within the service area or area of jurisdiction of the public entity may, by ordinance or resolution adopted by a majority of the members of the governing body after holding a public hearing upon notice and making appropriate findings of necessity for the adoption of a water conservation program, adopt and enforce a water conservation program to reduce the quantity of water used by those persons for the purpose of conserving the water supplies of the public entity.*

Cal. Water Code, § 375(a). Water Code Section 375(b) also provides the authority for pricing to encourage water conservation.

> *With regard to water delivered for other than agricultural uses, the ordinance or resolution may specifically require the installation of water-saving devices that are designed to reduce water consumption. The ordinance or resolution may also encourage water conservation through rate structure design.*

Metropolitan's Board of Directors has approved many policies and rules, codified in Metropolitan's own Administrative Code, which further provide Metropolitan the authority to ensure the availability of its water during times of shortages. For example, Administrative Code Section 3107 requires that any territory annexed to Metropolitan comply with Metropolitan's water use efficiency guidelines.

The Board has also ratified various policies and rules to implement a Water Supply Allocation Plan (WSAP) to address shortage conditions. Metropolitan's WSAP provides a standardized methodology for allocating supplies during times of shortage. The WSAP is authorized pursuant to the following Board actions:

- By Minute Item 43514, dated April 13, 1999, the Board adopted the WSDM Plan.
- By Minute Item 44005, dated June 17, 2000, the General Manager has the authority to reduce Interim Agriculture Water Program deliveries up to 30 percent prior to imposing any mandatory allocation under the WSDM Plan.
- By Minute Item 47393, dated February 12, 2008, the Board adopted the WSAP.
- By Minute Item 48376, dated August 17, 2010, the Board approved adjustments to the WSAP.

- By Minute Item 48803, dated September 12, 2011, the Board approved adjustments to the WSAP.
- By Minute Item 74526, dated February 11, 2014, the Board adopted the Water Supply Alert Resolution.
- By Minute Item 49979, dated December 9, 2014, the Board approved adjustments to the WSAP.

In addition to the statutes and other legal authorities set forth above, Metropolitan is empowered to implement and enforce its shortage response actions pursuant to various resolutions. For example, on April 11, 2016, Metropolitan's Board voted to adopt Metropolitan's 2015 UWMP and authorized its submittal to the State of California as stated in Resolution 9209. Metropolitan's 2015 UWMP contains Metropolitan's December 2014 WSAP in Appendix 4. Metropolitan's 2015 UWMP also describes in Section 2.4 Metropolitan's WSAP and WSDM Plan, which guides Metropolitan's planning and operations during both shortage and surplus conditions. Similarly, on May 11, 2021, Metropolitan's Board voted to adopt Metropolitan's UWMP and WSCP as stated in Resolutions 9279 and 9281, respectively. These two Resolutions authorize Metropolitan to implement and enforce its shortage response actions contained in the WSCP, which is attached as Appendix 4 to the 2020 UWMP.

Additionally, numerous agreements allow Metropolitan to take its core supplies and shortage response actions. Core supplies and supply augmentation actions are authorized by the agreements shown in 2020 UWMP Appendix 3: Justifications for Supply Projections, which include:

Colorado River Supplies

- 1931 Seven Party Agreement dated August 18, 1931
- Metropolitan's 1930, 1931, and 1946 water delivery contracts with the Secretary of the Interior
- Consolidated Decree of the Supreme Court of the United States in *Arizona v. California*
- 2003 Quantification Settlement Agreement (QSA) and related agreements
- 2005 Settlement Agreement with Quechan Indian Tribe
- Colorado River Interim Guidelines for Lower Basin Shortages and the Coordinated Operations for Lake Powell and Lake Mead
- 1988 IID-Metropolitan Conservation and Use of Conserved Water Agreement
- 1989 Approval Agreement
- 1989 Supplemental Approval Agreement
- August 2004 Forbearance and Fallowing Program Agreement with PVID
- Landowner Agreements for Fallowing in PVID
- 2003 Delivery and Exchange Agreement between Metropolitan and Coachella Valley Water District
- 2004 Storage and Interstate Release Agreement among Metropolitan, the Colorado River Commission of Nevada, Southern Nevada Water Authority, and the United States
- 2007 Lower Colorado Water Supply Project Contract among the United States, the City of Needles, and Metropolitan

- 2007 Lower Colorado River Basin Intentionally Created Surplus Forbearance Agreement among the Arizona Department of Water Resources, PVID, IID, the City of Needles, CVWD, Metropolitan, SNWA, and the Colorado River Commission of Nevada
- 2007 California Agreement for the Creation and Delivery of Extraordinary Conservation Intentionally Created Surplus among Metropolitan, PVID, IID, CVWD, and the City of Needles
- 2007 Agreement among the United States, the Colorado River Commission of Nevada, and the SNWA for the Funding and Construction of the Lower Colorado River Drop 2 Storage Reservoir Project
- 2007 Delivery Agreement between the United States and Metropolitan
- 2008 Metropolitan Notice of Election to Participate as a Party to the Drop 2 Funding Agreement
- 2009 Agreement among the United States, Metropolitan, the Colorado River Commission of Nevada, SNWA, and the Central Arizona Water Conservation District for a Pilot Project for Operation of the Yuma Desalting Plant
- 2010 Yuma Desalting Plant Pilot Project Delivery Agreement between the United States and Metropolitan
- 2012 Agreement among the United States, Metropolitan, the Colorado River Commission of Nevada, SNWA, and the Central Arizona Water Conservation District for a Pilot Program for the Conversion of Intentionally Created Mexican Allocation to Intentionally Created Surplus
- 2012 Interim Operating Agreement for Implementation of Minute No. 319 of the International Boundary and Water Commission
- 2012 Lower Colorado River Basin Forbearance Agreement for Binational Intentionally Created Surplus
- 2012 Binational ICS Delivery Agreement
- 2013 Agreement between Metropolitan and IID Regarding Binational Intentionally Created Surplus
- 2015 Amendment 1 to the California Agreement for the Creation and Delivery of Extraordinary Conservation Intentionally Created Surplus
- 2017 Agreement among the United States, Metropolitan, the Colorado River Commission of Nevada, SNWA, IID, and the Central Arizona Water Conservation District for a Pilot Program for the Conversion of Mexico's Water Reserve to Binational ICS
- 2017 Interim Operating Agreement for Implementation of Minute No. 323
- 2017 Binational ICS Agreement
- 2017 Binational ICS Delivery Agreement
- 2019 Lower Basin Drought Contingency Plan
- December 2019 Agreement for the Implementation of a Seasonal Land Fallowing Program
- Agreement for Seasonal Fallowing in Bard Unit (Farmer Fallowing Agreements

- May 2020 First Amended Agreement for the Implementation of a Seasonal Land Fallowing Program
- Agreement Relating to Supplemental Water among The Metropolitan Water District of Southern California, the San Luis Rey Settlement Parties, and the United States
- Amended and Restated Agreement between The Metropolitan Water District of Southern California and the San Diego County Water Authority for the Exchange of Water. This October 10, 2003 agreement provides for Metropolitan delivery of Exchange Water to SDCWA in exchange for conserved Colorado River water SDCWA makes available to Metropolitan at Lake Havasu.
- Agreement Between Imperial Irrigation District And San Diego County Water Authority For Transfer Of Conserved Water. This April 9, 1998 agreement, as amended, provides for IID to conserve water for transfer to SDCWA and establishes the price SDCWA pays to IID for the conserved water.
- Allocation Agreement. This October 10, 2003 agreement among the United States, CVWD, IID, SDCWA, Metropolitan, and the San Luis Rey Settlement Parties provides for the allocation of water conserved from the All-American Canal Lining Project and the Coachella Canal Lining Project, and Metropolitan's assignment to SDCWA of it rights to both canal lining projects.
- Colorado River Water Delivery Agreement: Federal Quantification Settlement Agreement. By this October 10, 2003 agreement, among the Secretary of the Interior. CVWD, IID, SDCWA, and Metropolitan, the Secretary agreed to deliver IID-SDCWA transfer water and canal lining water allocated to SDCWA to Metropolitan's Colorado River Aqueduct Intake at Lake Havasu for diversion by Metropolitan.

State Water Project Supplies

- 1960 Contract between the State of California and The Metropolitan Water District of Southern California for a Water Supply
- Port Hueneme Water Agency Annexation: By Minute Item 41728, dated January 9, 1996, Metropolitan's Board adopted Resolution 8487 granting the concurrent annexation of Annexation No. 32 to Calleguas Municipal Water District and The Metropolitan Water District of Southern California, and fixing Metropolitan's terms and conditions for the annexation
- 1996 Sublease Agreement between the Port Hueneme Water Agency and Metropolitan
- 1967 and 1983 Water Exchange Contract and Agreements with Desert Water Agency and Coachella Valley Water District
- 1984 Advance Delivery Agreement with Desert Water Agency and Coachella Valley Water District
- The 2003 Exchange Agreement with Desert Water Agency and Coachella Valley Water District
- November 2012 Letter Agreement with Coachella Valley Water District
- 2019 Amended and Restated Agreement for Exchange and Advance Delivery with Desert Water Agency and Coachella Valley Water District
- 1997 Arvin-Edison/Metropolitan Water Management Agreement

- 1998 Turn-in/out Construction and Maintenance Agreement between DWR, Kern County Water Agency, Arvin-Edison, and Metropolitan
- 1998-2002 Water Delivery and Return Agreements with DWR, Kern County Water Agency, Arvin-Edison, and Metropolitan
- 2004 Point of Delivery Agreement with DWR, Kern County Water Agency, and Metropolitan
- 2004 Introduction of Water into the California Aqueduct with DWR, Kern County Water Agency, and Arvin-Edison
- 2007 First Amended and Restated Agreement Between Arvin-Edison Water Storage District and The Metropolitan Water District of Southern California for a Water Management Program
- 2000 Coordinated Operating Agreement between Metropolitan and San Bernardino Valley Municipal Water District
- 2001 Coordinated Operating Agreement between Metropolitan and San Bernardino Valley Municipal Water District
- 2011 Coordinated Operating, Water Storage, Exchange and Delivery Agreement among Metropolitan, Municipal Water District of Orange County, and Irvine Ranch Water District
- 2013 San Gabriel Valley MWD Exchange and Purchase Agreement
- 2019 Board Approval of the High Desert Water Bank Agreement with Antelope Valley East Kern Water Agency
- 2001 Kern Delta/Metropolitan Principles of Agreement
- 2002 Kern Delta and Metropolitan Boards of Directors Approval
- 2007 DWR-Yuba County Water Agency Purchase Agreement
- 2007 DWR-Metropolitan Yuba Dry Year Program Participation Agreement
- 2014 Amended DWR-Metropolitan Yuba Dry Year Program Participation Agreement
- 2019 Amended and Restated Agreement Among The Metropolitan Water District of Southern California, Coachella Valley Water District, and Desert Water Agency for the Exchange and Advance Delivery of Water
- 2020 Amended DWR-Metropolitan Yuba Dry Year Program Participation Agreement
- 2021 Coordinated Operating Agreement. The Coordinated Operating Agreement between Metropolitan and San Bernardino Valley District was approved by Metropolitan's Board in March 2021. The agreement will terminate on December 31, 2035 unless there is an extension of the SWP Contract.
- <u>2013 San Gabriel Valley MWD Exchange and Purchase Agreement.</u> The agreement between Metropolitan and San Gabriel Valley MWD was executed in September 2013.
- <u>2013 Board Approval of the San Gabriel Valley MWD Exchange and Purchase Agreement.</u> In August 2013, Metropolitan's Board authorized entering into the agreement with San Gabriel Valley MWD.

In-Region Storage and Supplies

- November 1974 Memorandum of Understanding and Agreement on Operation of Lake Skinner
- November 1994 Memorandum of Understanding on Operation of Domenigoni Valley Reservoir (now known as Diamond Valley Lake)
- Elderberry Forebay Contract for Conditions for Use
- June 2002 Division of Safety of Dams Certificate of Approval
- October 1991 Final EIR for the Eastside Reservoir Project (Diamond Valley Lake)
- 1995 amendment to Metropolitan's SWP contract to include Article 54, "Usage of Lakes Castaic and Perris"
- November 1974 Memorandum of Understanding and Agreement on Operation of Lake Skinner
- June 2002 Division of Safety of Dams Certificate of Approval
- Principles for groundwater storage adopted by the Metropolitan Board in January 2000
- Resolution for Proposition 13 Funds adopted by the Metropolitan Board in October 2000
- Agreement executed with the DWR for Interim Water Supply Construction Grant Commitment Safe Drinking Water, Clean Water, Watershed Protection and Flood Protection (Proposition 13, Chapter 9, Article 4) providing for Metropolitan to administer $45 million in state Proposition 13 grant funds for groundwater reliability programs; October 2000
- Agreement executed for Long Beach Conjunctive Use Project, July 2002, amended in July 2003, October 2005, and November 2008
- Agreement executed for Live Oak Conjunctive Use Project, October 2002
- Agreement executed for Foothill Area Groundwater Storage Project, February 2003, amended in August 2006, April 2008, and February 2009
- Agreement executed for Chino Basin Programs, June 2003, amended in May 2004, August 2004, August 2005, May 2008, March 2009, September 2009, July 2010, and January 2015
- Agreement executed for Orange County Groundwater Storage Program, June 2003, amended in July 2004, December 2005, and July 2008
- Agreement executed for Compton Conjunctive Use Program, February 2005
- Agreement executed for Long Beach Conjunctive Use Project — Expansion in Lakewood, July 2005, amended in April 2006, August 2007, November 2008, and February 2010
- Agreement executed for Upper Claremont Basin Groundwater Storage Program, September 2005, amended in April 2008
- Agreement executed for Elsinore Basin Conjunctive Use Program, December 2006, amended in May 2008

These agreements are described in more detail in Appendix 3 to Metropolitan's 2020 UWMP.

If necessary, Metropolitan shall declare a water shortage emergency in accordance with CWC Chapter 3 (commencing with Section 350) of Division 1. In addition, Metropolitan shall coordinate with any city or county within which it provides water supply services for the possible proclamation of a local emergency, as defined in Section 8558 of the Government Code.

A.4.7. Financial Consequences of and Responses for Drought Conditions

A water shortage may be created by a reduction in water supply, an increase in water demand, or a combination of both. Metropolitan's shortage response actions include supply augmentation, demand management, and operational flexibility, all of which could impact Metropolitan financially. For example, exercising the options to take water from supply augmentation programs may increase costs. Similarly, operational changes could result in higher system costs and lower revenues from on-system hydropower generation, and an increase in conservation and outreach efforts would also increase costs. On the other hand, if core supplies from the SWP or the Colorado River were reduced, variable power costs to move water into the service area would likely decrease. Additionally, effective demand management during shortages tends to decrease Metropolitan's water sales when effective, thereby potentially reducing revenue for Metropolitan. From these various financial effects, there is a potential for expenditures exceeding revenues more than budgeted, thereby requiring unanticipated draws from reserves.

Variation in the amount of revenues is already part of Metropolitan's financial planning. Revenues vary according to regional weather and the availability of statewide water supplies. In dry years, local demands increase, and Metropolitan may receive higher than anticipated revenues due to increased sales volumes. In contrast, in wet years, demands decrease, and revenues drop due to lower sales volumes. In addition, statewide supply shortages such as those in 2009 and 2015 also affect Metropolitan's revenues. Such revenue surpluses and shortages could cause instability in water rates. To mitigate this risk, Metropolitan maintains financial reserves, with a minimum and target balance, to stabilize water rates during times of reduced water sales. The reserves hold revenues collected during times of high water sales and are used to offset the need for revenues during times of low sales. Metropolitan's practice of using reserves to buffer unexpected increases or decreases in budgeted revenue also applies to unexpected expenditure increases or decreases resulting from shortage responses.

Metropolitan uses its financial reserves to mitigate the impacts of water shortages. This policy applies to each of the six shortage levels described in this WSCP. Financial reserves create a buffer to reduce the financial impact of the water shortage. Other mitigation actions such as reducing operations and maintenance expenses, deferring capital projects, and rates/charges increases are part of Metropolitan's biennial budget and rate design cycle, are not used routinely to mitigate financial impacts of water shortage response actions.

Metropolitan's reserve policy provides for a minimum reserve requirement and target amount of unrestricted reserves at June 30 of each year. Funds in excess of the target amount are to be utilized for capital expenditures in lieu of the issuance of additional debt, or for the redemption, defeasance or purchase of outstanding bonds or commercial paper as determined by the Board. However, if the fixed charge coverage ratio (the amount necessary to cover all fixed costs) is at or above 1.2, amounts over the minimum may be expended for any lawful purpose of Metropolitan, as determined by the Board. Therefore, unrestricted reserves are intended to be available to address Metropolitan's shortage response actions, as well as the consequences of those actions, so long as its fixed charge coverage ratio is at or above 1.2.

A.4.8. WSCP Adoption and Refinement Procedures

WSCP Public Notice and Adoption

Metropolitan provided notice of the availability of the draft 2020 UWMP (including Appendix 11 which will also be a new Appendix 11 to its 2015 UWMP) and WSCP, and notice of the public hearing to consider adoption of both plans and Appendix 11 to the 2015 UWMP in accordance with CWC Sections 10621(b) and 10642, and Government Code Section 6066, and Chapter 17.5 (starting with Section 7290) of Division 7 of Title 1 of the Government Code. The public review drafts of the 2020 UWMP, Appendix 11 to the 2015 UWMP, and the WSCP were posted prominently on Metropolitan's website, mwdh2o.com, on February 1, 2021, more than 60 days in advance of the public hearing on April 12, 2021. The notice of availability of the documents was sent to Metropolitan's member agencies, as well as to cities and counties in Metropolitan's service area. In addition, a public notice advertising the public hearing in English and Spanish was published in 12 Southern California newspapers. The notification in English language newspapers was published on February 1 and 8, 2021. The notification was published on January 28-30, 2021 and February 1, 4-6, and 8, 2021 in Spanish language newspapers, satisfying the requirement for non-English language notification. Copies of: (1) the notification letter sent to the member agencies, cities and counties in Metropolitan's service area, and (2) the notice published in the newspapers are included in the 2020 UWMP Section 5. Table 5-3 in the 2020 UWMP provides a list of participating member agencies and other appropriate agencies that Metropolitan coordinated with in its regional planning, as well as the cities and counties that were notified about the preparation of its 2020 UWMP, Appendix 11 to the 2015 UWMP, and WSCP. In addition, the list of newspaper publications is included in Table 5-4.

Metropolitan held the public hearing for the draft 2020 UWMP, draft Appendix 11 to the 2015 UWMP, and draft WSCP on April 12, 2021, at the Board's Water Planning and Stewardship Committee meeting, held online due to COVID-19 concerns. On May 11, 2021, Metropolitan's Board determined that the 2020 UWMP and the WSCP are consistent with the MWD Act and accurately represent the water resources plan for Metropolitan's service area. In addition, Metropolitan's Board determined that Appendix 11 to both the 2015 UWMP and the 2020 UWMP includes all of the elements described in Delta Plan Policy WR P1, Reduce Reliance on the Delta Through Improved Regional Water Self-Reliance (Cal. Code Regs. tit. 23, § 5003) which need to be included in a water supplier's UWMP to support a certification of consistency for a future covered action. As stated in Resolutions 9279, 9280, 9281, the Board adopted the 2020 UWMP, Appendix 11 to the 2015 UWMP, and the WSCP and authorized their submittal to the State of California. Copies of Resolutions 9279, 9280, 9281 are included in the 2020 UWMP Section 5, and Resolution 9281 for the WSCP is attached to this WSCP as Attachment C.

Submission and Availability of Final 2020 UWMP, Appendix 11 to 2015 UWMP, and WSCP

In fulfillment of CWC Sections 10632(c) and 10645(a) and (b), Metropolitan's final 2020 UWMP, Appendix 11 to its 2015 UWMP, and its WSCP were posted on the mwdh2o.com website in May 2021, following their adoption by the Metropolitan board. This satisfies the requirement to make the plans available for public review and to make the WSCP available to Metropolitan's customers (which are its member agencies).

In fulfillment of CWC Sections 10632(c), 10635(c) and 10644(a)(1), Metropolitan also mailed copies of the final 2020 UWMP, Appendix 11 to the 2015 UWMP, and WSCP (in electronic pdf format) to the California State Library and all cities and counties within Metropolitan's service area within 30 days of Board adoption.

In June 2021, in fulfillment of CWC Section 10621(f) and Sections 10644(a)(1), (2), and (b), Metropolitan's final 2020 UWMP, Appendix 11 to the 2015 UWMP, and WSCP were electronically submitted to the State of California through DWR's WUE data website https://wuedata.water.ca.gov/secure/.

WSCP Reevaluation and Improvement Procedures

The WSCP will be periodically re-evaluated to ensure that its shortage risk tolerance is adequate and the shortage response actions are effective and up to date based on lessons learned from implementing the WSCP. The WSCP will be revised and updated during the UWMP update cycle to incorporate updated and new information. For example, new supply augmentation actions will be added, and actions that are no longer applicable for reasons such as program expiration will be removed. However, if revisions to the WSCP are warranted before the UWMP is updated, the WSCP will be updated outside of the UWMP update cycle. In the course of preparing the Annual Assessment each year, Metropolitan staff will routinely consider the functionality the overall WSCP and will prepare recommendations for Metropolitan's Board of Directors if changes are found to be needed.

WATER SURPLUS AND DROUGHT MANAGEMENT PLAN

METROPOLITAN WATER DISTRICT OF SOUTHERN CALIFORNIA

TABLE OF CONTENTS

EXECUTIVE SUMMARY

INTRODUCTION

The Water Surplus and Drought Management (WSDM) Plan for the Metropolitan Water District of Southern California (Metropolitan) is a ten-year plan that will be used to direct Metropolitan's resource operations to help attain the region's 100% reliability goal. The WSDM Plan recognizes the interdependence of surplus and shortage actions and is a coordinated plan that utilizes all available resources to maximize supply reliability. The overall objective of the WSDM Plan is to ensure that shortage allocation of Metropolitan's imported water supplies is not required.

The central effort in developing the WSDM Plan was a participatory process involving Metropolitan and its member agencies. Metropolitan staff and member agency representatives coordinated the Plan's development during a series of meetings of the Rate Refinement Team.

To lay a foundation for the WSDM Plan, participants in the Rate Refinement Process developed a set of proposed WSDM Principles and Implementation Goals which were subsequently adopted by the Metropolitan Board of Directors in September 1998. These Principles and Implementation Goals outline fundamental policies for guiding surplus and shortage management and establish a basis for dealing with shortages in an equitable and efficient manner.

WSDM PRINCIPLES AND IMPLEMENTATION GOALS

Guiding Principle

- Metropolitan will encourage storage of water during periods of surplus and work jointly with its Member Agencies to minimize the impacts of water shortages on the region's retail consumers and economy during periods of shortage.

Supporting Principles

- Maintain an ongoing coordinated effort among Metropolitan and its Member Agencies to encourage efficient water use, develop cost-effective local resource programs, and inform the public on water supply and reliability issues

- Encourage local and regional storage during periods of surplus and use of storage during periods of shortage

- Manage and operate Metropolitan's regional storage and delivery system in coordination with local facilities to capture and store surplus water in local groundwater and surface reservoirs

- Arrange for secure sources of additional water from outside the region for use during periods of shortage

- Call upon sources of additional water from outside the region and water stored locally to meet the needs of consumers and protect the economy during periods of shortage

WSDM Plan Implementation Goals

- Avoid mandatory import water allocations to the extent practicable

- Equitably allocate imported water on the basis of agencies' needs

  Considerations to create an equitable allocation of imported water may include:

  - Impact on retail consumers and economy
  - Reclamation/Recycling
  - Conservation
  - Population and economic growth
  - Investment in local resources
  - Change and/or loss of local supply
  - Participation in Metropolitan's Non-firm (interruptible) programs
  - Investment in Metropolitan's facilities

- Encourage storage of surplus supplies to mitigate shortages and improve water quality

SURPLUS AND SHORTAGE ACTIONS

The region's ability to implement a long-term WSDM Plan results from the significant investments Metropolitan and its member agencies have made in a variety of resources since 1991. These additional resources include increased local conservation and water recycling, improvements in the reliability of imported supplies, increased regional storage, and increased conjunctive use groundwater programs. Together these improvements allow a comprehensive approach to water management.

The growing variety of resources available to the region is transforming Metropolitan from an agency with relatively modest storage capacity to one that will have storage sufficient to manage many shortages without impacts to its member agencies or retail customers. To attain this level of reliability, all storage programs and facilities, along with conservation, recycling, and other programs, must be managed as an integrated set of regional resources. To accomplish this, the WSDM Plan establishes the linkage between surplus and shortage resource management actions.

When imported supplies exceed projected demands for imported water within Metropolitan's service area, Metropolitan can operate available storage facilities to maximize the benefits of stored water to its member agencies. A number of factors affect Metropolitan's ability to divert surplus water into storage. Some of these factors include facility outages, system capacity, water quality (including requirements for managing total dissolved solids), and varying supply and demand patterns. The WSDM Plan provides a description of storage options available to Metropolitan and a framework for storing water in these programs and facilities when surplus supplies are available.

Except in severe or extreme shortages (defined in the Introduction) or emergencies, Metropolitan's resource management will allow shortages to be mitigated without impacting retail Municipal and Industrial (M&I) customers. A list of resource management actions and their descriptions are provided below. This list emphasizes critical storage programs and facilities, and conservation programs that make up part of Metropolitan's response to shortages. The order in which these actions are presented does not imply the exact operational management of resources that would occur during a shortage, rather it represents a general framework and guide. In fact, several actions are likely to be taken concurrently. Many factors will dictate the exact order in which these actions will be taken during shortages. One action, however, will have an assigned prioritization: the curtailment of Full Service (firm) deliveries will be last. The following summarizes the drought actions:

- Draw on storage in the Eastside Reservoir Project
- Draw on out-of-region storage in Semitropic and Arvin-Edison
- Reduce/suspend long-term seasonal and groundwater replenishment deliveries
- Draw on contractual groundwater storage programs in the region
- Draw on State Water Project (SWP) terminal reservoir storage (per Monterey Agreement)
- Call for extraordinary drought conservation and public education
- Reduce Interim Agricultural Water Program (IAWP) deliveries
- Call on water transfer options contracts
- Purchase transfers on the spot market
- Implement the allocation of Metropolitan's imported supplies to its member agencies

For the ten-year period addressed by the WSDM Plan, 1999-2008, the majority of shortage contingencies will be managed by withdrawals from storage, groundwater management and options transfers. Shortages managed using these actions would not impact the quantity of water delivered to member agencies for consumptive uses. In fact, when coupled with other drought actions such as extraordinary conservation and reduction of agricultural deliveries, it is fully expected that an allocation of firm imported water supplies will not be necessary during the next ten years. Under this worse-case scenario, an approach to allocate Metropolitan's firm imported water supplies in a fair and equitable manner will be developed.

The overall policy objective of the allocation method will be to minimize the impacts to any one agency and the region as a whole. To meet that objective, the method of allocating firm imported supply will account for:

- Each agency's demands on Metropolitan,
- Each agency's local resources
- Each agency's total retail demands.

The WSDM Plan allocation method would address each of these supply and demand components and account for each agency's conservation and recycled water programs. A pricing structure will be coupled with the WSDM allocation method to accomplish two goals:

- Encourage conservation and water recycling
- Ensure that the regional impact of the shortage is as small as possible

To provide as much water as possible without changing wholesale prices, the allocation of all available supplies will be made at the prevailing rates for firm deliveries. In order to encourage conservation to the level of allocation, the rate for agency usage from 100-102% of its allocation will be the Full Service rate plus $175. Usage above 102% of allocated supply will be charged at three times the Full Service rate. Any substantial change in Metropolitan's water rate structure may require these rates to be revised.

During severe or extreme shortage conditions, public outreach will play a critical role in shaping consumer response. Public information campaigns will send clear signals if extraordinary drought conservation is required. An effective public information campaign requires a joint effort among Metropolitan and its member agencies. Under this Plan, the administration of the Public Information and Government Affairs program will be the responsibility of a Drought Program Officer (DPO). The DPO will be responsible for integrating the various activities in these areas, coordinating efforts with Metropolitan's Board of Directors and member agencies, and designing the region-wide messages for the general public and various target audiences. Important constituencies are residential users, industrial and institutional users, business interests, agricultural users, elected officials, officials of various agencies such as the Department of Water Resources, and the media.

INTEGRATED RESOURCES MANAGEMENT

Throughout the Integrated Resources Planning process and the development of the WSDM Plan, extensive analysis of resource management strategies focused on maximizing supply reliability while minimizing overall resource costs. Various management strategies were analyzed trader shortage scenarios based on historical hydrologic data. The WSDM Plan presents a resource management framework to guide Metropolitan's integrated approach to supply management.

The resource management framework does not dictate a scripted response to shortage or surplus. The framework recognizes the complexity and variety of conditions that require action. Supporting this framework are general rules that describe the actions to be taken in each stage of surplus or shortage. These rules depend on shortage stage, account for monthly delivery requirements, and depend on when various supplies would be available.

One of the fundamental trade-offs in dealing with supply shortages is the need to maintain flexibility while providing supply certainty to member agencies and consumers. A central focus of the WSDM Plan is the analysis of information about supplies and demands. When do various pieces of information about the supply/demand balance become more certain? When should this information impact policy-making and trigger various resource actions? The WSDM Plan addresses these questions and the actual implementation of the Plan during a shortage.

Appendix A of this report provides a ten-year simulation of projected demands and supplies showing an example of how the region can maintain 100% reliability.

INTRODUCTION

The Metropolitan Water District of Southern California (Metropolitan) provides water to a service area covering approximately 5,200 square miles. Over 16.5 million people live within the service area, which supports a $500 billion economy. Metropolitan provides supplemental supplies to twenty-seven member agencies, both retail and wholesale agencies, who in turn provide water to over three hundred cities and local agencies providing supplies at the retail level. In recent years Metropolitan supplemental deliveries have accounted for about one-half to two-thirds of the region's total water demands. With supplies from its Colorado River Aqueduct (CRA) and the State Water Project (SWP), Metropolitan delivers water for municipal and industrial (M&I) uses, agricultural uses, and augmentation of local storage.

As part of the implementation of the regional Integrated Resources Plan (IRP), Metropolitan and its member agencies have developed the Water Surplus and Drought Management (WSDM) Plan for Southern California. This ten-year plan will direct Metropolitan's resource operations to help attain the region's 100% reliability goal. Over this ten-year period, the WSDM Plan will be updated to account for changes impacting supplies from the Colorado River and California's Bay-Delta. In the past, Metropolitan has developed drought management plans that simply addressed shortage actions and primarily focused on issues of short-term conservation and allocation of imported water. The WSDM Plan recognizes the interdependence of surplus and shortage actions and is a coordinated plan that utilizes all available resources to maximize supply reliability. The overall goal of the WSDM Plan is to ensure that shortage allocation of Metropolitan's imported water supplies is no---At required.

Because it addresses both surplus and shortage contingencies, the WSDM Plans draws clear distinctions among the terms *surplus, shortage, severe shortage,* and *extreme shortage.*

> ***Surplus****: Supplies are sufficient to allow Metropolitan to meet Full Service demands, make deliveries to all interruptible programs (replenishment, long-term seasonal storage, and agricultural deliveries), and deliver water to regional and local facilities for storage.*
>
> ***Shortage****: Supplies are sufficient to allow Metropolitan to meet Full Service demands and make partial or full deliveries to interruptible programs, sometimes using stored water and voluntary water transfers.*
>
> ***Severe Shortage****: Supplies are insufficient and Metropolitan is required to make withdrawals from storage, call on its water transfers, and possibly call for extraordinary drought conservation and reduce deliveries under the IAWP.*
>
> ***Extreme Shortage****: Supplies are insufficient and Metropolitan is required to allocate available imported supplies.*

WSDM PRINCIPLES AND IMPLEMENTATION GOALS

The central effort in developing the WSDM Plan was a participatory process involving Metropolitan and its member agencies. Metropolitan staff and member agency representatives coordinated the Plan's development during a series of meetings of the Rate Refinement Team and the Integrated Resources Planning Workgroup. To lay a foundation for the WSDM Plan, participants in the Rate Refinement Process developed a set of "WSDM Principles and Implementation Goals."

Guiding Principle

- Metropolitan will encourage storage of water during periods of surplus and work jointly with its Member Agencies to minimize the impacts of water shortages on the region's retail consumers and economy during periods of shortage.

Supporting Principles

- Maintain an ongoing coordinated effort among Metropolitan and its Member Agencies to encourage efficient water use and cost-effective local resource programs and to inform the public on water supply and reliability issues

- Encourage local and regional storage during periods of surplus and use of storage during periods of shortage

- Manage and operate Metropolitan's regional storage and delivery system in coordination with local facilities to capture and store surplus water in local groundwater and surface reservoirs

- Arrange for secure sources of additional water from outside the region for use during periods of shortage

- Call upon sources of additional water from outside the region and water stored locally to meet the needs of consumers and protect the economy during periods of shortage

WSDM Plan Implementation Goals

- Avoid mandatory import water allocations to the extent practicable

- Equitably allocate imported water on the basis of agencies' needs

  Considerations to create an equitable allocation of imported water may include:
  - Impact on retail consumers and economy
  - Reclamation/Recycling
  - Conservation
  - Population and economic growth
  - Investment in local resources
  - Change and/or loss of local supply
  - Participation in Metropolitan's Non-firm (interruptible) programs
  - Investment in Metropolitan's facilities.

- Encourage storage of surplus supplies to mitigate shortages and improve water quality

REGIONAL RESOURCES AND DEMANDS

Southern California receives its water supplies from a variety of different sources, both local to the region and imported from outside the region. These sources are summarized below.

Local Supplies

Local supplies include groundwater pumping of local aquifers, surface reservoir production, recycled water, and supplies imported through wheeling arrangements or through the Los Angeles Aqueduct, which is owned and operated by the City of Los Angeles. Local supplies have, in the past, provided as much as 2.1 million acre-feet (maf) of water to meet the region's water demands. By far the largest component of local supplies is groundwater pumping, providing over 75% of historical local supplies.

Colorado River Supplies

The distribution and management of Colorado River water is governed by a complex body of laws, court decrees, compacts, agreements, regulations, and an international treaty collectively known as the "Law of the River." Metropolitan's entitlement is established by the fourth and fifth priorities of California's Seven Party Agreement, included in Metropolitan's 1931 and 1946 contracts with the Secretary of the Interior. These priorities provide 550,000 acre-feet (af) per year and 662,000 af per year, respectively. In addition, Metropolitan holds a surplus water contract for delivery of 180,000 af. The physical capacity of the CRA is slightly in excess of 1.3 maf per year, based on a pumping capacity of 1,800 cubic feet per second (cfs). Metropolitan's long-held objective is to maximize the availability of Colorado River water, up to the maximum capacity of the CRA, subject to environmental, contractual, legal, political, financial, and institutional constraints. A California 4.4 Plan is being developed among California parties that will help ensure that full CRA deliveries are maintained, while addressing the concerns of the other Colorado River basin states that rely on the river. The California 4.4 Plan includes core transfers (such as the IID/MWD conservation agreement and the proposed IID/SDCWA transfer), system conservation (such as the lining of the All American Canal), offstream storage (such as the Arizona groundwater storage program), dry year option transfers (such as PVID land fallowing), and river re-operations.

State Water Project

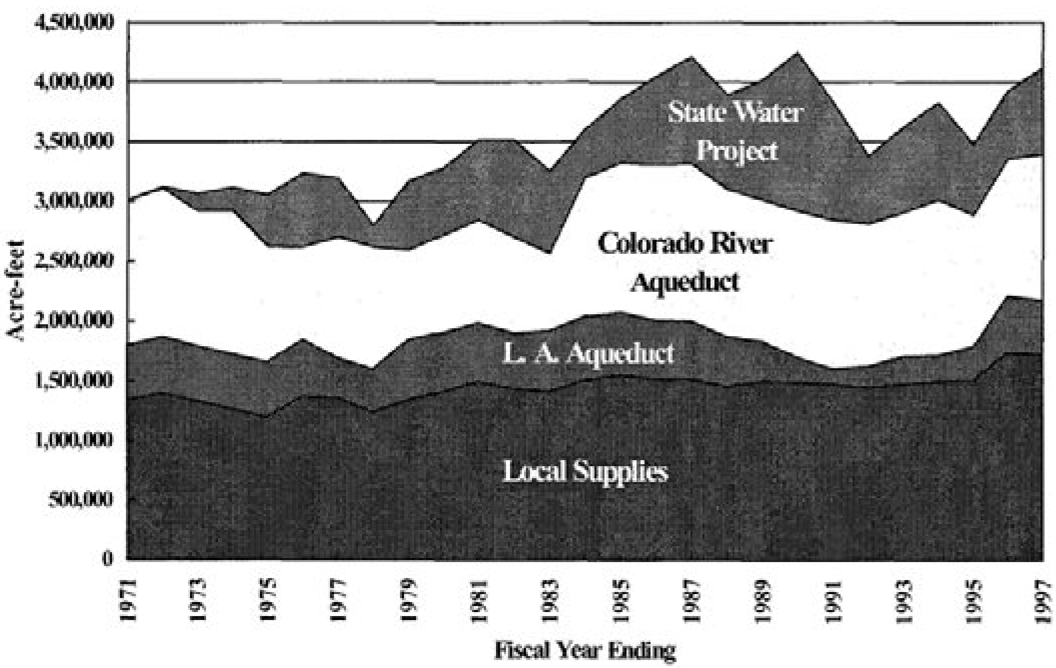
Metropolitan is one of 29 water agencies that have contracted with the State of California, through the Department of Water Resources (DWR), for water deliveries from the SWP system. Metropolitan's contracted entitlement is for 2.01 maf per year, or about 48 percent of the total contracted entitlement of 4.2 maf per year. SWP deliveries to Metropolitan are made via the SWP's California Aqueduct.

Initial SWP facilities, completed in the early 1970's, have produced average supply yields adequate to meet just over half of the total contracted entitlement. While it was intended that additional SWP facilities would be constructed as SWP contractor demands increased up to their contracted entitlements, few facilities have been constructed since that time.

The SWP obtains its supplies primarily from the Sacramento River Basin. About half of the total supply diverted from the Delta for the SWP is regulated flow from the Feather River (a tributary to the Sacramento River), while the other half is unregulated flow from runoff downstream of Sacramento River reservoirs and from other rivers that flow into the Delta. The Sacramento River watershed is subject to wide annual variations in total runoff. The Sacramento River Index (SRI), which measures runoff in the watershed, has averaged about 18 maf per year over the last 90 years. However, runoff varies widely from year to year. For example, the SRI measured 7.8 mafin 1994 and 32.5 mafin 1995.

Figure 1 shows the historical total regional supply production by type. As shown in Figure 1, water supplies were as high as 4.25 mafin 1990 and within two years dropped to 3.4 mar, a 20% decrease.

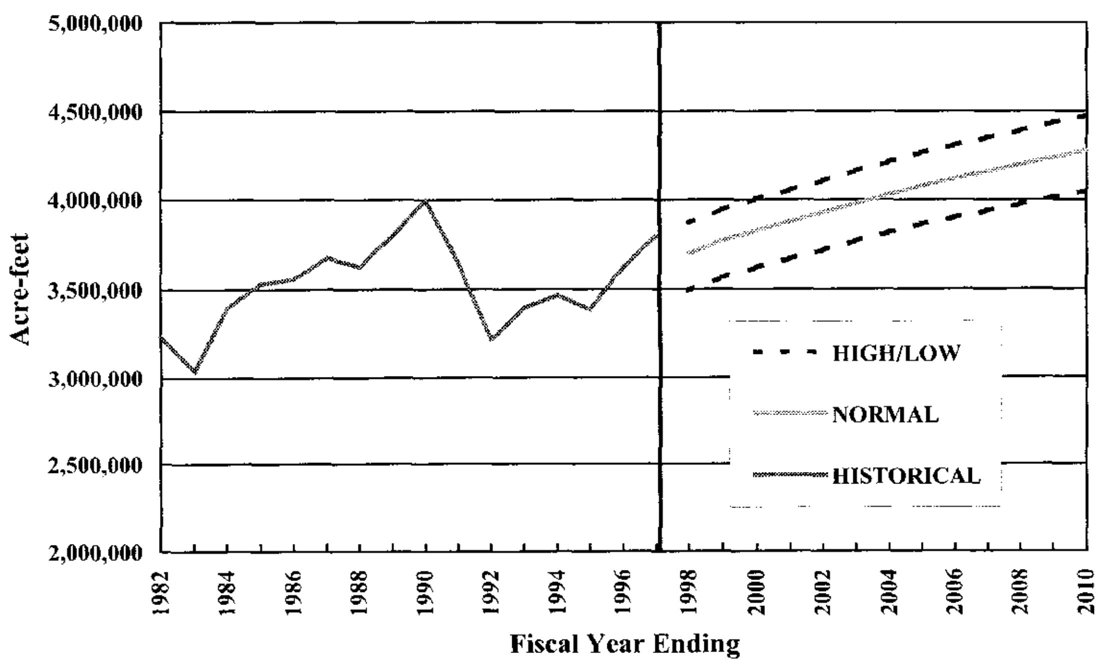
Figure 1. Historical Supply Production by Type of Supply



RETAIL DEMANDS

From 1982 through 1995, the region experienced retail water demands averaging 3.5 mar. In dry years retail demands are approximately 5 to 7% greater than normal years, while demands in wet years are about 6 to 8% below normal demands. Under normal weather conditions, assuming full implementation of conservation best management practices, total regional retail demands are projected to increase from about 3.7 mar in 1997 to almost 4.3 mar in 2010. Without conservation, demands in 2010 would be about 10 to 12% greater than projected. Increases in retail demand are driven by demographics and economics, including changes in population, housing, employment, and income. Figure 2 shows the historical and projected retail demands in Metropolitan's service area.

Figure 2. Regional Retail Water Demands



The historical variability in demands from 1982 to 1997 is mainly due to weather and the economy. In 1983, extreme wet weather caused a significant drop in retail demands. During the period from 1985 to 1990, hot and dry weather coupled with a strong economy resulted in increased demand from 3.5 maf to 4.0 maf, a 14% increase. In 1991, the 5th year of a prolonged drought, conditions forced many communities to implement mandatory supply reductions. These mandatory reductions coupled with extraordinary drought conservation caused a 10 to 15% decrease in retail demands for the region. In addition, the period between 1992 and 1995 was very wet (with the exception of 1994, which was dry), and was a period of severe economic recession. Southern California alone lost some 700,000 jobs from 1990 through 1995. The combination of wet weather, economic recession, and conservation resulted in demands decreasing by over 17%.

DEMANDS ON METROPOLITAN

For many member agencies, Metropolitan's water deliveries represent a supplemental supply. Most member agencies have local water supplies, but agencies differ in how much their supplies alone can meet their respective retail demands. Local supplies are often base-loaded (maximized subject to various constraints) and purchases from Metropolitan are used to meet remaining demands. In addition, to meeting consumptive demands, Metropolitan's deliveries are used to replenish local groundwater and surface reservoirs. To project demands on Metropolitan, projections of member agency's retail water demands and local water supplies are made. Local supplies are then subtracted from retail demands to get consumptive demands on Metropolitan. A projection of Metropolitan's long-term seasonal and replenishment deliveries are made based on safe groundwater yield and weather/hydrology.

Metropolitan forecasts its demands for three different broad categories: Full Service, Seasonal (reservoir storage and groundwater replenishment delivered for shift or long-term storage purposes and sold at a discount), and Agricultural (deliveries of water sold at a discount for agricultural use). Overall, demands on Metropolitan can vary -+ 11 to 18% from normal conditions due to weather and hydrology.

The following four figures show historical and projected demands on Metropolitan by category. Figure 3 shows Basic Water Deliveries, Figure 4 shows Seasonal Water Deliveries, Figure 5 shows Interim Agricultural Water Program (IAWP) Deliveries, and Figure 6 shows Total Water Deliveries for Metropolitan.

INTEGRATED RESOURCES PLANNING

To ensure supply reliability under various drought conditions, Metropolitan and its member agencies developed an Integrated Resources Plan (IRP). The IRP, adopted by Metropolitan's Board of Directors in January 1996 and periodically updated, guides Metropolitan's resource and capital improvements investments. The region's ability to develop a long-term WSDM Plan results from the significant investments Metropolitan and its member agencies have made in resources since 1991. To date, these investments include:

- Local supplies: Metropolitan co-funded over 23 local projects and 200 conservation programs that will yield a total of 160,000 af per year.

- **Colorado River Aqueduct:** Metropolitan developed transfers and storage programs to help ensure a full aqueduct. The landmark Metropolitan/Imperial Irrigation District Conservation Program (IID), will result in a savings of 107,000 af per year. Storage programs in Arizona and California, combined with the IID savings, yield a total of 280,000 af of annual core, dry year options, and storage supply.

- **State Water Project:** Metropolitan and other parties negotiated the Bay-Delta Accord and the Monterey Amendment. The Bay-Delta Accord and subsequent efforts will increase the reliability of Metropolitan's entitlement deliveries. The Monterey Amendment provides access to 220,000 af of SWP storage.

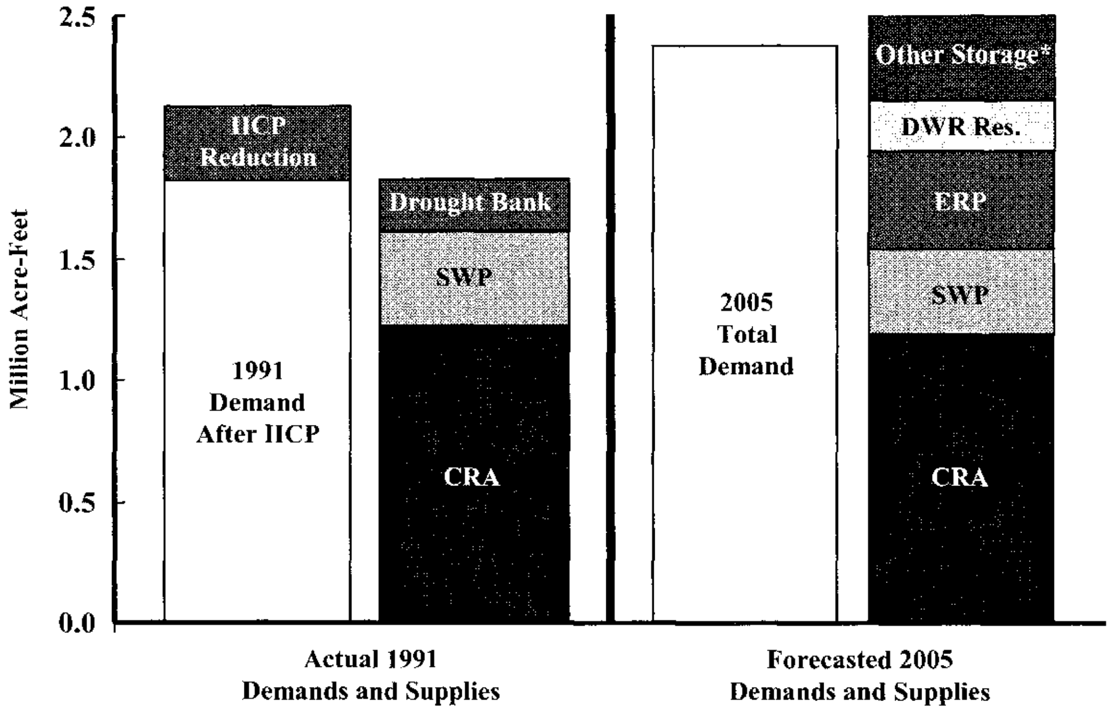
- **In-Basin Storage:** Metropolitan is constructing the Eastside Reservoir Project, with 800,000 af of storage (400,000 af of which is emergency storage for use in case of facility failure as a result of earthquake or other event).

- **Groundwater Conjunctive Use Storage:** Metropolitan developed a conjunctive use storage program in the North Las Posas Basin in Ventura County with an anticipated capacity of 210,000 af and a dry-year withdrawal rate of up to 70,000 af.

- **Transfers and Storage:** Metropolitan developed the Semitropic Storage Program, with 350,000 af of storage and dry-year withdrawals averaging about 60,000 af. Metropolitan also approved the Arvin-Edison Storage and Transfer Program, with 250,000 af of storage and dry-year withdrawals averaging about 70,000 af. Metropolitan is also exploring storage and transfer programs with the Coachella Valley Water District and the Cadiz Land Company.

As a result of these investments, it is anticipated that Metropolitan and its member agencies will be 100% reliable over the next 10 years even under a repeat of the 1991 drought condition. Figure 7 compares actual Metropolitan demands and supplies during 1991 (the last year in a multiyear severe drought) and projected demands and supplies in year 2005 (assuming a repeat of 1991 conditions). In 1991, the region faced shortages that required Metropolitan to allocate water under the Incremental Interruption and Conservation Plan (IICP). The reduction in deliveries came after demands had already been reduced as a result of local conservation. In addition, water had to be purchased from the Governor's drought emergency water bank. By the year 2005 with the investments made to date, Metropolitan's additional water supplies will be more than adequate to meet demands under a repeat of the 1991 drought event--even with increased demands due to growth.

Figure 7. Historical and Projected Metropolitan Supplies and Demands Under Drought Conditions



* Groundwater management, Semitropic Storage Program, and Arvin-Edison Storage Program

SURPLUS AND SHORTAGE RESOURCE ACTIONS

Metropolitan's investments in water resources, facilities, and programs has transformed it from an agency with relatively modest storage capacity to one that will have storage sufficient to manage many shortages without negative impacts to its member agencies or retail customers. To attain this level of reliability, storage programs and facilities, along with conservation, recycling, and other programs, must be managed as an integrated set of regional resources. To accomplish this, the WSDM Plan recognizes the linkage between surplus and shortage resource management actions.

SURPLUS ACTIONS

The combination of Metropolitan's regional storage facilities, such as Lake Mathews, Lake Skinner, the future Eastside Reservoir Project, and the storage capacity available to Metropolitan in Castaic Lake and Lake Perris as a result of the Monterey Amendment, allows Metropolitan great flexibility in managing its water resources. The development of storage programs both outside and within the service area provides even greater flexibility in storing surplus water. Each of the storage facilities and programs plays an important role in achieving Metropolitan's reliability goal.

When imported supplies exceed projected demands for imported water within Metropolitan's service area, Metropolitan can operate storage facilities to maximize stored water to benefit its member agencies. A number of factors affect Metropolitan's ability to divert surplus water into storage. Some of these factors include facility outages, system capacity, water quality (including requirements for managing total dissolved solids), and varying supply and demand patterns. This section provides a description of storage options available to Metropolitan and a framework for storing water in these programs and facilities when surplus supplies are available.

Storage of Colorado River Supplies

Metropolitan has participated in a number of programs to maximize the reliability of supplies from the Colorado River. The landmark Metropolitan/Imperial Irrigation District Conservation Program will result in a savings of 107,000 af per year. These supplies will increase the reliability of Metropolitan's entitlement of Colorado River water. Other programs yield shortage benefits by increasing amounts of water stored for use during shortages. Between August 1992 and July 1994, Metropolitan and the Palo Verde Irrigation District conducted a Test Land Fallowing Program. Approximately 20,000 acres of farmland in the Palo Verde Valley were not irrigated, saving 186,000 af of water which was stored in Lake Mead for later use by Metropolitan. With Arizona and Nevada water agencies, Metropolitan is participating in a Central Arizona Groundwater Storage Demonstration Program that has encouraged the storage of water. To date, 139,000 af of supplies have been stored in groundwater basins in Central Arizona. The Desert Coachella program is an exchange and storage program with agencies situated along the Colorado River Aqueduct. Metropolitan releases Colorado River water for storage in the Coachella Groundwater Basin. Metropolitan then exchanges these supplies for the participating agencies' SWP supplies. These programs serve as models for future programs that could increase the reliability of Colorado River supplies. Metropolitan continues to explore other possible options that would increase the reliability of supplies. The California 4.4 Plan is being developed among California parties to increase storage programs for Colorado River supplies. In addition to core transfers and conservation programs, the California 4.4 Plan includes offstream storage (such as the Arizona groundwater storage program), dry year option transfers (such as PVID land fallowing), and river re-operations. These programs, in conjunction with favorable supply determinations by the Secretary of Interior, will ensure the highest possible reliability of Colorado River supplies.

In addition to the programs mentioned above, the Colorado River system itself contributes to the high reliability of Metropolitan's Colorado River supplies. Currently, the average Colorado River runoff exceeds basin-wide demands by over 1.0 maf per year. The Colorado River system also contains a great deal of reservoir storage capacity. The total storage capacity in the Colorado River Basin is approximately 60 maf, almost four times the Colorado River's average annual flow. For much of 1997, system storage levels were at 80% or more of total capacity. These factors allow the Bureau of Reclamation, operators of the Colorado River system, to store significant supplies for use during shortages.

Storage of State Water Project Supplies

Total storage capacity is a critical factor in comparing the operations of the Colorado River system with the SWP. On average, both systems have similar amounts of water available on an annual basis. The SWP's watersheds in the Sacramento River Basin have produced about 18 maf per year over the long term, as represented by the Sacramento River Index (SRI.) Long-term runoff on the Colorado River has averaged more than 16 maf annually since 1906. However, the ability to carry over unused water from a wet year for use in a dry year differs substantially between the two systems. State Water Project storage facilities have storage capacity of about 4.5 maf, while system storage in the Colorado River Basin totals nearly 60 maf. This gives the operators of the Colorado River reservoirs much more flexibility in storing unused water from a wet year for use in a subsequent dry year.

When water from the SWP cannot be put to immediate use in Metropolitan's service area, the water may be stored for future use. Provided storage capacity is available, the water may remain in either Oroville Reservoir (as SWP storage for delivery to all contractors the following year) or San Luis Reservoir (as carryover storage assigned to Metropolitan). Through the carryover storage program, as amended by the Monterey Amendment, Metropolitan can place a maximum of 200,000 af per year of allocated supplies in SWP surface reservoirs. The program also allows for carryover storage in non-project facilities, including surface reservoirs and groundwater basins. In the case of carryover storage in San Luis Reservoir, SWP supplies allocated to but unused by a contractor may, under certain conditions, be assigned as carryover if storage capacity is available at the end of the calendar year. However, carryover water stored for a contractor has lower priority than storage of SWP water and consequently "spills" first as San Luis Reservoir fills.

Also, in a wet year such as 1995, low demands may allow DWR to operate San Luis Reservoir nearly full, eliminating any possibility of contractor carryover storage into the following year. As a result, carryover storage on the SWP may not be possible, and even when possible, is subject to spilling.

Due to these carryover storage limitations, Metropolitan has invested a great deal to expand its ability to store surplus SWP supplies. Metropolitan has entered into a number of water transfer and storage agreements. The Semitropic Water Banking and Exchange program allows Metropolitan to store up to 350,000 afin the groundwater basin underlying the Semitropic Water Storage District. The storage and withdrawal capacities of the program are shared with other participants in the storage program, with Metropolitan's share equaling 35%. Dry-year withdrawals will average about 60,000 af.

Metropolitan and the Arvin-Edison Water Storage District have developed a program that allows Metropolitan to store water in the groundwater basin in the Arvin-Edison service area. The program would allow the storage and withdrawal of 250,000 af of supplies over the next 25430 years. Dry-year withdrawals will average about 70,000 af.

Storage in Regional Facilities

In addition to the storage of Colorado River and SWP supplies outside the region, Metropolitan has established a number of programs for storing supplies within the region. Metropolitan owns and operates two main surface reservoirs, Lake Mathews and Lake Skinner, which have a combined storage of about 226,000 af. Only a small portion of this capacity is available for shortages, with the balance being used to regulate flows in Metr0Politan's delivery system. The Eastside Reservoir Project, currently under construction, will have a total capacity of 800,000 af, with approximately 400,000 af of operational drought and seasonal storage and 400,000 af of emergency storage. Through the Monterey Amendment, Metropolitan obtained the fight to use up to 220,000 af of water stored in the SWP terminal reservoirs. However, withdrawals from these terminal reservoirs must be replaced within five years.

Metropolitan and its member agencies have established the cyclic storage program to increase storage in groundwater basins within the service area. Regional groundwater basins offer an economical way for Metropolitan to improve supply reliability by storing water within the service area. This makes water readily accessible in times of need, either in emergency situations or during shortages. Some limitations are imposed by the fact that such water can generally only be used through pumping from the groundwater basin by an overlying member agency or local agency. Storage in groundwater basins takes place either by direct replenishment (spreading or injection), or through in-lieu means. Spreading (or injection) is desirable because direct measurement of the amount of stored water is a relatively simple, verifiable transaction. The main disadvantage to direct spreading is that spreading can occur only under certain conditions. For example, spreading cannot occur when spreading facilities are being used to capture local storm runoff for flood control purposes, or when the amount of local runoff precludes the need for imported water to replenish the basins. Also, spreading basins require frequent maintenance to assure maximum efficiency. These and other conditions can limit the ability to deliver water for spreading at a time when surplus supplies are available.

In-lieu replenishment allows most member agencies to participate in groundwater replenishment without needing direct access to replenishment facilities. Their wells, in effect, become their replenishment facilities. Both direct and in-lieu replenishment from 1986 through 1990 served the region well during the critical drought years from 1991 through 1993.

The overall objective of the various storage programs is to maximize the availability of imported water during times of need by storing surplus water in a strategic manner and utilizing the storage available within the region. Many factors affect the availability of storage capacity and Metropolitan's ability to move water to and from various facilities. After reviewing the full range of shortage actions available to Metropolitan, a framework for prioritizing the full range of surplus and shortage actions will be presented.

In addition to pricing incentives used to encourage local agencies to store water in groundwater basins, Metropolitan has developed a conjunctive use contractual storage program with the Calleguas MWD in the North Las Posas Basin. Metropolitan will fund the construction of wells which will be called upon to meet demands during dry years. This program will yield a dry year supply of about 70,000 af.

SHORTAGE ACTIONS

Except in severe or extreme shortages or emergencies, Metropolitan's management of available resources will allow shortages to be mitigated without negatively impacting retail M&I demands. Below is a list of drought actions that will be taken during periods of shortage. The goal of these actions is to avoid, to the extent practicable, the allocation of Metropolitan's firm supplies. The order in which these actions are presented does not imply the exact operational management of resources that would occur. In fact, several actions are likely to be taken concurrently. Many factors dictate the particular order in which actions will be taken during an actual shortage, although it is clear that the last action will be the curtailment of firm deliveries to the member agencies.

- Draw on storage in the Eastside Reservoir Project
- Draw on out-of-region storage in Semitropic and Arvin-Edison
- Reduce/suspend long-term seasonal and groundwater replenishment deliveries
- Draw on contractual groundwater storage programs in the region
- Draw on SWP terminal reservoir storage (per Monterey Agreement)
- Call for extraordinary drought conservation and public education
- Reduce IAWP deliveries
- Call on water transfer options contracts
- Purchase transfers on the spot market
- Implement an allocation of Metropolitan's imported supplies to its member agencies

Even with dedicated programs to meet the reliability goal for the region, proper management and operations of these resources is critical to ensure reliability. The prioritization of both surplus and shortage actions need to account for several important criteria. It is also important to recognize that these criteria will need to be balanced. The criteria include:

Location: Out-of-region storage is more vulnerable than in-basin-storage due to the risks of seismic events. To only maximize out-of-region storage will put reliability at risk.

Take capacity: Surface reservoirs generally have the ability to be filled and drawn down very quickly. Certain groundwater storage programs have limited take capacities--requiring several years at full take capacity to withdraw **all** available storage. Stored water will be balanced so that dry year supplies are maximized.

Cost: Programs vary with respect to their marginal operating costs. Program actions will be taken to maximize supply reliability while minimizing cost.

Flexibility: Not all storage programs and transfers offer the same flexibility to Metropolitan. Some programs can only meet specific overlying demands, while others can meet demands anywhere in the system.

DESCRIPTIONS OF RESOURCE ACTIONS

Draw on storage in the Eastside Reservoir Project: Withdrawals from the Eastside Reservoir Project would provide a flexible supply for meeting a shortage. Eastside Reservoir Project supplies can be drawn upon quickly. The amount of water drawn from the Eastside Reservoir Project before exercising other shortage actions will depend on the severity of the shortage and the overall condition of other resources available to Metropolitan.

Draw on out-of-region storage in Semitropic and Arvin-Edison programs: Out-of-region programs such as Semitropic and Arvin-Edison provide cost-effective shortage supplies. These supplies also provide flexibility, as they can be distributed as effectively as any SWP supplies coming into Metropolitan's service area. Exercising these programs relatively early in the order of actions reduces the risk of leaving supplies out-of-region. Based upon the ratio of storage capacity to take capacity, these programs will generally provide supplies over several years. This provides the rationale for calling on these programs relatively early in a shortage.

Reduce Long-Term Seasonal and Replenishment Deliveries, and call on cyclic storage accounts: Certain interruptible supply programs provide benefits during shortage. Reducing deliveries to interruptible programs established for storage purposes, while continuing expected levels of groundwater production, allows limited supplies to go toward meeting direct consumptive uses. In addition, calling on cyclic storage accounts can extend the replenishment needs for several years. Most replenishment supplies would be expected to be interruptible for a minimum of two years before agencies would be allowed to claim a local supply adjustment on such supplies. Some programs have longer interruption requirements. For example, most Groundwater Recovery Programs are governed by contracts that require supply production through a three-year interruption in service.

Draw on contractual groundwater storage programs: In-region contractual groundwater programs provide cost-effective supplies that would be drawn upon during shortages. These programs are also limited by their take capacities and generally have several years of withdrawals in storage. For this reason, these programs might be called upon before withdrawing heavily from surface reservoir storage.

Draw on SWP terminal reservoir storage: The storage available in the SWP terminal reservoirs provides a flexible and cost-effective shortage supply. Supplies withdrawn from this program must be replaced within five years of withdrawal. For this reason, the storage in these reservoirs would be reserved for more serious shortage conditions and would be utilized after the programs and facilities listed above were used to meet the shortage.

Call for extraordinary drought conservation: Voluntary conservation programs have historically been effective in reducing water demand during drought. However, voluntary conservation programs are not without impact to the retail customer and can be perceived as a failure of water agencies to properly plan for shortages. Therefore, the call for extraordinary drought conservation will only be taken with the consent of Metropolitan's Board of Directors.

Reduce agricultural deliveries: The Interim Agricultural Water Program (IAWP) offers interruptible water to southern California's agricultural industry at discounted rates. These supplies will be interrupted as part of Metropolitan's shortage actions. Metropolitan will work with IAWP participants to provide as much advance warning of interruption as possible. The IAWP reflects current policies toward agricultural water users. The policies underlying this program are due to be reviewed during the ten-year period of the WSDM Plan. The WSDM Plan will be changed accordingly.

Call on water transfer option contracts: Transfer options programs provide cost-effective supplies when the region is faced with reducing deliveries to meet consumptive demands. These programs might also be used to increase storage levels in Metropolitan storage facilities. Replenishment of these facilities reduces the risk of leaving available supplies outside the region and helps to protect the region during extended shortages.

Purchase transfers on the spot market: During the 1987-92 drought, the Drought Water Bank proved to be one mechanism for California to reduce the overall impacts of the shortage. However, the cost of spot market supplies may cause Metropolitan to use them as a last increment of supply before the region implements reductions in M&I deliveries. It is likewise possible that availability and cost will make spot market options more favorable under certain conditions. If this occurs then spot market supplies will be sought prior to calls on option transfers. However, participation in the spot market may be restricted to those agencies that have already taken significant actions in response to the shortage.

Implement allocation plan: As the final stage in responding to shortages, Metropolitan will implement an allocation plan to deliver reduced supplies to its member agencies. The issues of allocation and the methods of allocation are outlined in the following section.

ALLOCATION OF SUPPLY FOR M&I DEMANDS

The equitable allocation of supplies is addressed by the Implementation Goals established for the WSDM Plan, with the first goal being to "avoid mandatory import water allocations to the extent practicable." The second fundamental goal is to "equitably allocate imported water on the basis of agencies' needs." Factors for consideration in establishing the equitable allocation include retail and economic impacts, recycled water production, conservation levels, growth, local supply production, and participation and investment in Metropolitan's system and programs. In the event of an extreme shortage an allocation plan will be adopted in accordance with the principles of the WSDM Plan.

INTEGRATED RESOURCE MANAGEMENT STRATEGY

Throughout the Integrated Resources Planning process and the development of the WSDM Plan, extensive analysis of resource management strategies focused on maximizing supply reliability while minimizing overall resource costs. Various management strategies were analyzed under shortage scenarios based on historical hydrologic data. Certain strategies yield high reliability but incur very high costs. This is the case for strategies that utilize relatively costly transfer programs early in a shortage while maintaining high storage levels. If a shortage is short, this results in high transfer costs and shortage storage programs that are not fully utilized. Other strategies draw more heavily on storage early in a shortage and do not use options transfer programs. Later in a shortage, the yields from these transfer programs, combined with low yields from depleted storage facilities, might not make up for continuing or deepening shortages. Overall, such approaches may be inexpensive to pursue at the wholesale level but have high costs associated with retail level impacts. The resource management framework presented results from extensive analysis of various strategies for managing available resources under a variety of surplus and shortage conditions. Although the extent to which various actions are exercised may still vary depending on specific shortage conditions, the ordering presented does reflect Metropolitan's anticipated order of actions during shortages.

RESOURCE MANAGEMENT FRAMEWORK

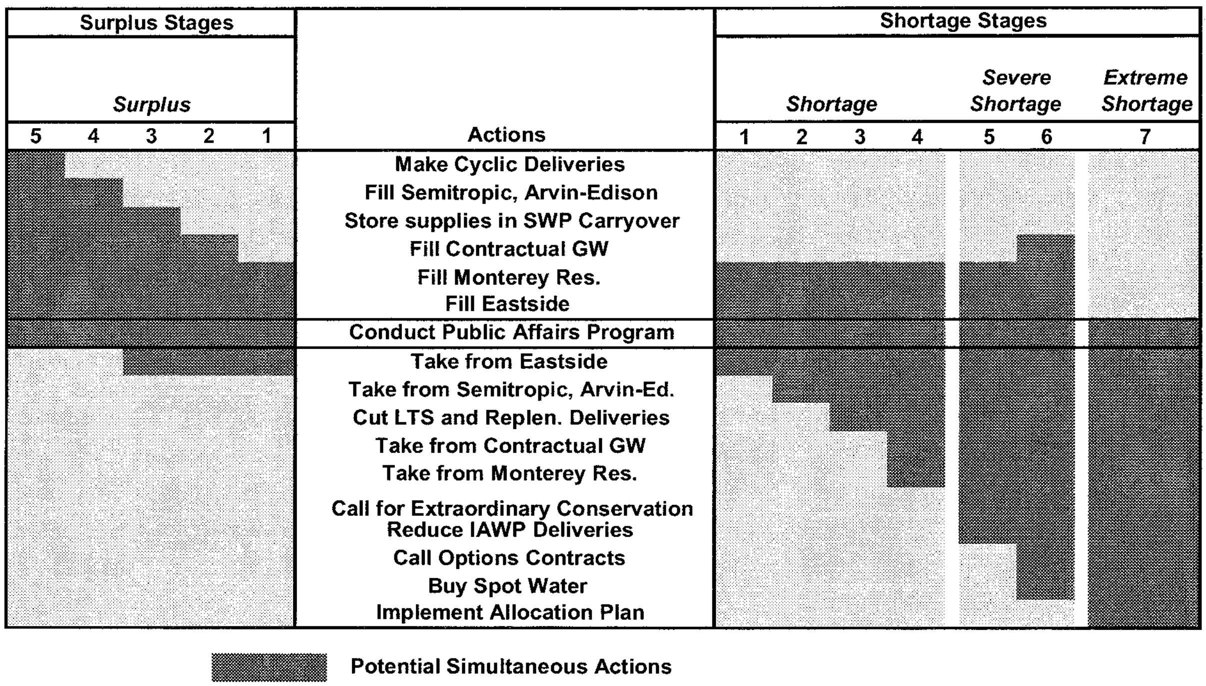
The analysis of surplus and shortage actions yields a water management framework that accounts for the degree or "stage" of surplus and shortage. These stages are defined by parameters such as storage levels and expected SWP supplies. Each stage has associated actions that could be taken as part of the response to prevailing shortage conditions. For example, Surplus Stage 1 might have as associated actions to place water in the highest-priority storage resources. Figure 8 shows the mapping between actions and stages. The darkly shaded diagonal area identifies actions that can be undertaken concurrently, while the lightly shaded areas show actions that will not be taken. For example, Metropolitan will not withdraw water from most storage resources during a surplus.

Figure 8 highlights several aspects of the WSDM Plan's approach to supply management. First and most importantly, it does not dictate a response to shortage or surplus. The framework recognizes the complexity and variety of conditions that could require various responses. Supporting this framework are general "rule curves" that dictate the extent to which particular actions are taken in various stages of surplus or shortage. For example, the rule curves indicate approximately how much water should be taken from the Eastside Reservoir Project before calling on supplies from the Semitropic or Arvin-Edison storage programs. If a shortage were greater than the desired initial withdrawal from the Eastside Reservoir Project, then Stage 2 actions would be taken. The rule curves for a particular resource would take into account shortage stage, monthly delivery requirements, and when various supplies are available.

Surplus and Shortage Stages are determined by the total amount of water that would be stored or produced by exercising the actions in that Stage. Overall storage levels in each stage are determined by the extent to which storage is increased or reduced by earlier actions. Therefore, each Stage is defined by supplies (stored or produced) and an approximate overall level of storage remaining in all resources. Up through Shortage Stage 4, the actions taken will not result in negative impacts to any consumptive uses. Shortage Stages 1 through 4 constitute shortage management without retail level impacts. The conservation efforts and reductions in IAWP deliveries in Shortage Stage 5 will result in retail impacts.

Action by the Metropolitan Board of Directors would be required before actions corresponding to Stages 5, 6, and 7.

Figure 8. Resource Stages and Actions Matrix



The Stages and Actions Matrix (Figure 8) is read from the center moving outward. Moving from the center to the left, are actions that Metropolitan will take during surplus conditions. For instance, in a Stage 3 Surplus, Metropolitan will be adding water to the Eastside Reservoir Project, the Monterey Reservoirs (if any water is due for repayment), Contractual Groundwater Programs, and carryover storage on the State Water Project. Moving from the center to the right are actions that Metropolitan will take during periods of shortage. For instance, in a Stage 3 Shortage, Metropolitan will be pulling water from the Eastside Reservoir Project, the Semitropic and Arvin Edison programs, and interrupting deliveries of Long-Term Seasonal and Replenishment program water. In addition, the Stages and Actions Matrix allows for surplus actions to be taken during shortages and vice versa, but these actions are strictly a result of prudent water management. For example, in a Stage 6 Shortage, Figure 8 shows Metropolitan potentially filling the Eastside Reservoir Project, the Monterey Reservoirs, and contractual groundwater programs while calling on spot transfers and buying spot water. Through these actions Metropolitan will be ensuring that water supply opportunities during a drought are realized--ultimately adding to the drought reserves of southern California.

Figure 8 also highlights the on-going efforts by Metropolitan and its member agencies in the conduct of public outreach and active conservation programs. Through all conditions, effective pubilc outreach and conservation programs are an integral part of Metropolitan's management of resources. In addition to ongoing conservation and water efficiency programs, Stage 5 of the Stages and Actions Matrix calls for participation of the citizens of southern California to take extraordinary conservation measures to cut water demand during droughts.

As with the listing of shortage actions earlier in the report, the Stages/Actions matrix in Figure 8 only highlights certain programs and response actions. However, unlike the discussion of actions earlier, Figure 8 is intended to convey Metropolitan's currently anticipated ordering for those actions listed. As the supply and demand outlooks, programs, and other factors continue to change, the analysis of the ordering of actions will continue during the ten-year period of the WSDM Plan.

SUPPLY CERTAINTY AND THE TIMING OF RESOURCE ACTIONS

One of the fundamental trade-offs in dealing with supply shortages is the need to maintain flexibility while providing supply certainty to member agencies and consumers. A central focus of the WSDM Plan is the analysis of information about supplies and demands. When do various pieces of information about the supply/demand balance become more certain? When should this information impact policy-making and trigger various resource actions? The WSDM Plan addresses these questions and the actual implementation of the Plan during a shortage.

Figure 9 shows a hypothetical shortage year. With respect to the supply and demand outlook, a typical shortage year will have periods of certainty and stability, and other periods of relative uncertainty and transition. Important supply components--such as the SWP, CRA, Los Angeles Aqueduct (LAA), and local supplies--are closely monitored through the early part of the year. These supplies and demands are fairly well-known through the April-September period. Storage is assessed in the post-summer period and decisions about certain programs, such as long-term (LT) seasonal deliveries could be made at this time.

Figure 9. Water Supply Outlook Throughout the Year

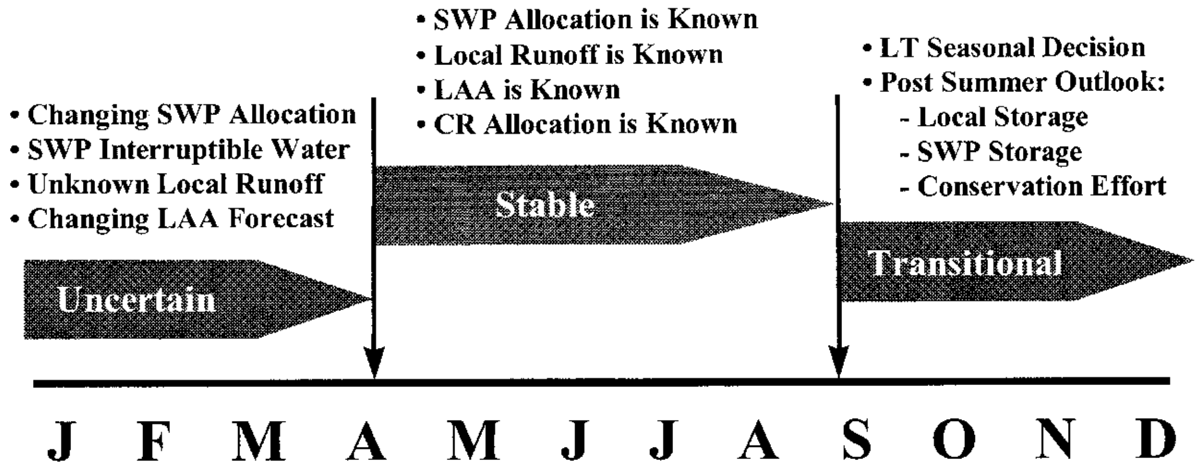


Figure 10 presents the annual schedule for actions taken in response to shortage conditions. Starting in January, an initial supply/demand report will be presented to the Metropolitan Board of Directors. SWP allocations are still only estimates in January and become more certain towards April and May. Demands for Metropolitan deliveries depend in part on how the winter hydrology develops and the condition of local supplies. These factors start to become known during the February-March period and will be reported to the Board in the Supply Report Update. By April-May, the outlook for imported supplies is known to a fairly high degree of certainty and a Final Supply Report will be produced. The May-September period will be one in which the import supply situation does not change drastically and drought policies can be implemented. Demands can be more or less than anticipated as a result of unusually hot or cool weather. At the end of summer, carryover SWP storage will be determined. October through December is a transitional period during which early assessments of available supplies for the following year will be made. During this period, Board actions would determine the management of various Metropolitan programs such as long-term seasonal (LTS) and IAWP deliveries. The following list presents major information and decision points during the year.

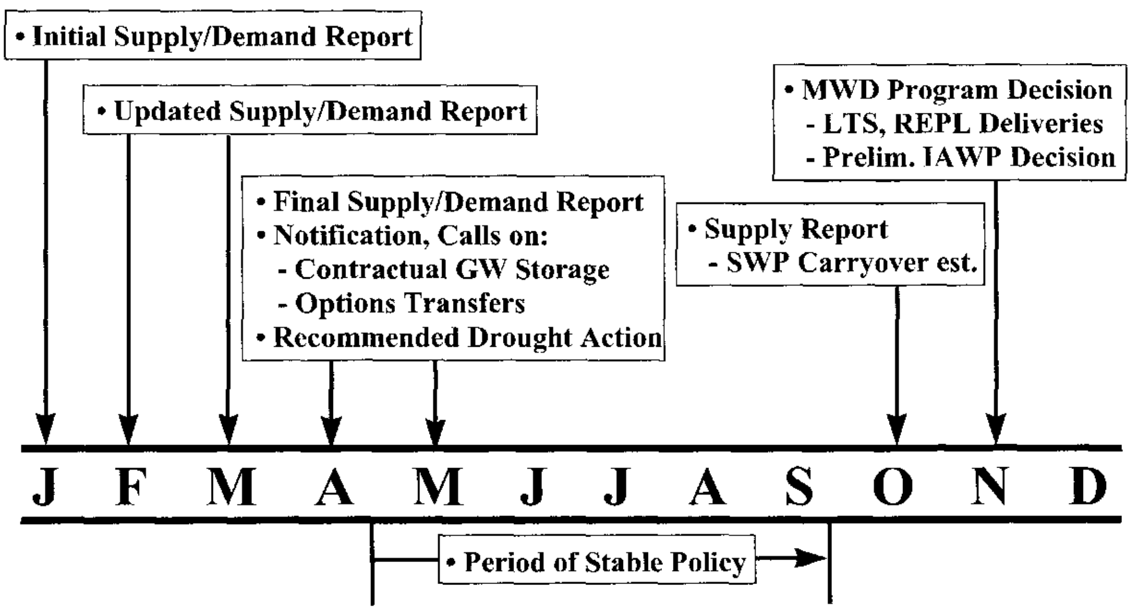
Month	Information/Action
January	Initial Supply/Demand Reports
February, March	Updated Supply/Demand Reports
April, May	Final Supply/Demand Report
	Notification on Contractual GW and Options Transfer Programs
	Recommended Drought Actions
May-September	Stable Policy Period
October	Supply and Carryover Storage Report
November	MWD Program Decisions - LT Seasonal, Replenishment, IAWP

Figure 10. One Year of a Hypothetical Shortage - Supply and Demand Reports and Response Actions



PUBLIC OUTREACH AND CONSERVATION

Mechanisms are already in place to implement most of the water management actions and programs that are addressed in the WSDM Plan. Under the majority of supply and demand conditions, the actions of Metropolitan's Board of Directors, the General Manager, the operational activities of Metropolitan, and its member agencies would constitute all actions necessary to mitigate the shortage. Several aspects of the WSDM Plan, however, require additional attention to the administration of programs and actions. In particular, a shortage contingency requires special programs in the areas of public and governmental affairs and conservation. Metropolitan maintains an on-going public information program to encourage efficient water use. Public outreach programs are conducted at all times under both surplus and shortage conditions (see Figure 8). The actions discussed in this section constitute special actions in times of shortage.

During shortage conditions, public outreach will play a critical role in shaping consumer response. Public information campaigns need to send clear signals if extraordinary drought conservation is to achieve needed reductions in demands. Given Metropolitan's diverse set of customers and the varying impacts that shortages can have on different consumer groups, an effective public information campaign will require a joint effort among Metropolitan and its member agencies. Under this Plan, the administration of the Public Information and Government Affairs programs will be the responsibility of a Drought Program Officer (DPO). The DPO will be responsible for integrating the various activities in these areas, coordinating efforts with Metropolitan's Board of Directors and member agencies, and designing the region-wide messages for the general public and various target audiences. Important constituencies that have been identified in the process are residential users, business interests, agricultural users, elected officials, officials of various agencies (such as the Department of Water Resources), and the media.

Many conservation programs, such as Metropolitan's ultra-low flush toilet rebate program, are driven by member agency requests. Based on history, Metropolitan expects member agency requests to increase during droughts. Metropolitan is committed to increasing overall conservation program funding to meet member agency requests during droughts and attain higher levels of savings. These programs will be implemented by Metropolitan and member and local agency conservation staff. As many of the short-term conservation objectives during a shortage would be dependent upon an effective public information program, the Drought Program Officer will also be responsible for monitoring the effectiveness of the augmented conservation programs. A monthly conservation reporting process will be implemented. Quarterly estimates of regional conservation will be developed to track the progress of various actions in mitigating the shortage.

APPENDIX A: RESOURCE AND STORAGE SIMULATION

The Water Surplus and Drought Management Plan (WSDM Plan) uses the Stages and Actions Matrix (Figure 8) as a guide for the operation of storage and transfers for the next ten years, 1999-2008**.** Metropolitan asserts that the investments that Metropolitan and its member agencies have made in water supply and storage, managed in a coordinated manner as presented in the WSDM Plan, will be sufficient to assure that retail firm water demands will be met 100% of the time through the year 2008. Metropolitan performed an extensive analysis of projected water demands, current and expected water supplies, along with hydrologic variations to support this assertion. Appendix A presents a summary of this analysis which includes statistical probabilities of actions under the WSDM Plan and two illustrative examples of how supply resources may be used in the future under worst-case drought events. Although the WSDM Plan is intended to be in effect through 2008, for the purposes of analysis the planning horizon was extended through 2010.

The WSDM Plan seeks to define the operational envelope for the Metropolitan system into the near future. Although the WSDM Plan only looks out ten years, it nonetheless involves the operation of some storage and water transfer projects that have not yet become fully operational. This makes the estimation of storage and transfers operations difficult. Compounding this problem is the lack of certainty around future demands, economic conditions, or even the weather over the next ten years. To manage these uncertainties, Metropolitan has developed a computer based simulation model called the Integrated Resources Planning Simulation Model or IRPSIM.

IRPSIM uses a modeling method known as sequentially indexed monte-carlo simulation. Simply put, the model looks at projected regional retail demand and supplies of water over the next twelve years and adjusts each, up or down, based on an assumed pattern of future weather. For instance, if Metropolitan expected the weather over the next twelve years (1999-2010) to be the same as the last twelve years (1987-1998), then IRPSIM would adjust the projected 1999 demands and supplies based on the historical 1987 hydrology, and adjust the projected 2000 demands and supplies using the historical 1988 hydrology, and so on. One obvious drawback to this approach is that Metropolitan does not know what future weather will be. Therefore, Metropolitan runs the models over and over again until all recorded hydrologies, 70 in all, have been tried. In this way, Metropolitan can look at probabilistic results of being in shortage year by year through 2010.

Although the projections of water supplies used in this analysis required certain assumptions to be made, they were based on most likely or probable outcomes. In most cases, projected water supplies represented projects that are currently operational, under construction, or in the final stages of negotiations. The following represents a summary of these assumptions:

- Local recycling and groundwater recovery: assumes currently operational projects with expected increases in supply yield as demand increases

- Conjunctive use groundwater storage: assumes Las Posas (under final stages of construction) and implementation of similar programs which are under negotiation (such as Raymond, Orange, and Chino Basins)

- Semitropic and Arvin-Edison storage: assumes use of both programs which are operational with water already stored

- Eastside Reservoir Project: assumes use of non-emergency storage from the reservoir currently under construction and an initial fill projected to start in approximately one year

- The Monterey Reservoirs: assumes use of State Water Project terminal reservoir supplies, Castaic and Perris Reservoirs, per the Monterey Amendment

- Colorado River Aqueduct: assumes a full aqueduct through the implementation of the California Plan (including lining of All American and Coachella canals, SD/IID water transfer/exchange, conjunctive use off-aqueduct storage, and river re-operations)

- State Water Project: assumes continuance of Bay-Delta Accord (with only current facilities)

One way of viewing the result of Metropolitan's WSDM Plan analyses is by summary statistics. Table A- 1 gives the probabilities of shortage actions over the next twelve years.

Table A-1. Probability of Shortage Stage[1] by Forecast Year

1999	13%	13%	11%	7%	3%	0%	O%
2000	13%	13%	11%	9%	3%	O%	0%
2001	19%	17%	13%	10%	6%	O%	0%
2002	19%	17%	13%	10%	4%	1%	0%
2003	19%	19%	14%	11%	4%	0%	0%
2004	20%	19%	16%	13%	4%	0%	0%
2005	21%	19%	17%	13%	6%	O%	O%
2006	21%	19%	19%	13%	6%	0%	0%
2007	23%	20%	19%	13%	4%	0%	0%
2008	26%	21%	19%	16%	6%	1%	0%
2009	26%	24%	19%	17%	6%	1%	0%
2010	26%	26%	19%	19%	6%	1%	O%

Table A-1 can be read in one of two ways, by column or row. The Stage 7 column indicates that there are no historical weather conditions that require allocation over the next twelve years. This is the single most important conclusion of the WSDM Plan analysis. The Stage 6 column indicates that only in a few years--2002, and 2008 through 2010--would Metropolitan need have a need for option or spot transfer water. Read by row, Table A-1 indicates that in the year 2008 there is a 21% likelihood of taking some water from the Eastside Reservoir Project, a 19% likelihood of taking water from Semitropic or Arvin-Edison storage programs, a 17% likelihood of interrupting long-term seasonal and replenishment deliveries for two years, and so on. It should be noted that these probabilities represent the best current estimates by Metropolitan, but are based entirely on historical weather conditions. Conditions that fall outside of historical ranges, either in duration or severity, are not represented by this data.

Another way to view the WSDM Plan analysis is by observing the operation of a single hydrology. Table A-2 provides an example of resource operations for the period 1999 through 2010 assuming a repeat of the 1923 through 1934 hydrology. The table provides descriptions of hydrologic conditions to aid in understanding the example.

[1] Stage 1 consists of withdrawal from the Eastside Reservoir Project. Stage 2 consists of the above plus withdrawals from the Semitropic and Arvin-Edison water storage and transfer projects. Stage 3 consists of the above plus an interruption of Long-Term Seasonal and Replenishment discount water. Stage 4 consists of the above plus withdrawal from contractual groundwater programs and the Monterey Reservoirs. Stage 5 consists of the above plus a call for extraordinary drought conservation and interruption in agricultural discount water. Stage 6 consists of the above plus calls on option contract water and purchases of water on the open market. Stage 7 consists of the above plus allocation of remaining shortages. For a full description of stages and action, see Surplus and Shortage Resource Actions section and Figure 8 above.

For instance, 1923 was considered to be a dry year in southern California (defined as less than 9 inches of rain at the Los Angeles Civic Center) and is categorized by the California Department of Water Resources (DWR) as a below normal year for State Water Project deliveries. In this example, 1923 weather increases southern California's demand for water and decreases imported State Water Project supplies. The Colorado River Aqueduct supplies are influenced by yet another hydrologic indicator, but for the next ten year Metropolitan expects the Aqueduct to be full.

Table A-2 indicates that retail water demands in 1999, assuming a 1923 hydrology, will be 3.979 million acre-feet (maf). Adding expected long-term seasonal and replenishment demands of 0.165 maf gives a regional total water demand of 4.144 maf. After subtracting local supplies of 2.192 maf, which are also adjusted for 1923 weather, Metropolitan expects to see a demand of 1.952 maf. In 1999, under a 1923 hydrology, Metropolitan expects to see 2.954 maf of supply. This is enough to meet all expected demands and put over 1.0 maf into storage.

The 1923 through 1934 hydrology is significant because it starts and ends dry with little recovery in the middle. However, even in these most adverse conditions the actions proposed by the WSDM Plan provides the region with enough water to avoid shortage allocation. Again the most important result of this example is read from the last line, which indicates that there are no remaining shortages through 2008

Table A-3 provides a second example of using the 1980 through 1991 hydrology. This hydrology contains the most significant drought in recent record, ending with a critically dry year on the State Water Project that is expected to yield a mere 0.389 maf. However, even under these conditions the WSDM Plan provides a method to avoid firm water allocation.

The analyses performed using the prioritized action of the Stages and Actions Matrix support Metropolitan's assertion that water supply reliability can be attained through the use of regional storage, interruption of discounted water supplies, and transfers. And, through the implementation of the WSDM Plan, Metropolitan does not expect to allocate firm water deliveries for at least the next ten years.

List of Acronyms

AF – Acre-feet
CUP – Groundwater Conjunctive Use Program
CWD – County Water District
DWP – Drought Management Plan
IAWP – Interim Agricultural Water Program Reductions and Rates
IICP – Incremental Interruption and Conservation Plan
IRP – Integrated Resources Plan
GPCD – Gallons per Capita per Day
M&I – Municipal and Industrial
MWD – Municipal Water District
RUWMP – Regional Urban Water Management Plan
SWP – State Water Project
WSAP – Water Supply Allocation Plan
WSDM – Water Surplus and Drought Management

Definitions

Extraordinary Supplies- Deliberate actions taken by member agencies to augment the total regional water supply only when Metropolitan is allocating supplies through the WSAP.

Groundwater Recovery- The extraction and treatment of groundwater making it usable for a variety of applications by removing high levels of chemicals and/or salts.

In-lieu deliveries- Metropolitan-supplied water bought to replace water that would otherwise be pumped from the groundwater basins.

Seawater Barrier- The injection of fresh water into wells along the coast to protect coastal groundwater basins from seawater intrusion. The injected fresh water acts like a wall, blocking seawater that would otherwise seep into groundwater basins as a result of pumping.

Section 1: Introduction

Calendar Year 2007 introduced a number of water supply challenges for the Metropolitan Water District of Southern California (Metropolitan) and its service area. Critically dry conditions affected all of Metropolitan's main supply sources. In addition, a ruling in the Federal Courts in August 2007 provided protective measures for the Delta Smelt in the Sacramento-San Joaquin River Delta which brought uncertainty about future pumping operations from the State Water Project. This uncertainty, along with the impacts of dry conditions, raised the possibility that Metropolitan would not have access to the supplies necessary to meet total firm demands[1] and would have to allocate shortages in supplies to the member agencies.[2]

In preparing for this possibility, Metropolitan staff worked jointly with the member agency managers and staff to develop a Water Supply Allocation Plan (WSAP). The WSAP includes the specific formulas for calculating member agency supply allocations and the key implementation elements needed for administering an allocation should a shortage be declared. The WSAP became the foundation for the urban water shortage contingency analysis required under Water Code Section 10632 and was incorporated into Metropolitan's 2010 Regional Urban Water Management Plan (RUWMP).

Section 2: Development Process

Member Agency Input

Between July 2007 and February 2008, Metropolitan staff worked cooperatively with the member agencies through a series of member agency manager meetings and workgroups to develop a formula and implementation plan to allocate supplies in case of shortage. These workgroups provided an arena for in-depth discussion of the objectives, mechanics, and policy aspects of the different parts of the WSAP. Metropolitan staff also met individually with fifteen member agencies for detailed discussions of the elements of the recommended proposal. Metropolitan introduced the elements of the proposal to many nonmember retail agencies in its service area by providing presentations and feedback to a number of member agency caucuses, working groups, and governing boards. The discussions, suggestions, and comments expressed by the member agencies during this process contributed significantly to the development of this WSAP.

Board of Directors Input

Throughout the development process Metropolitan's Board of Directors was provided with regular progress reports on the status of this WSAP, with oral reports in September, October, and December 2007, an Information Board of Directors Letter with a draft of the WSAP in November 2007, and a Board of Directors Report with staff recommendations in January 2008. Based on Water Planning and Stewardship Committee discussion of the staff recommendations and further review of the report by

[1] Firm demands are also referred to as uninterruptable demands; likewise non-firm demands are also called interruptible demands.

[2] See Appendix A: Metropolitan Member Agencies.

the member agencies, refinements were incorporated into the WSAP for final consideration and action in February 2008. The WSAP was adopted at the February 12, 2008 Board of Directors meeting.[3]

The 12-Month Review Process

When the Board adopted the WSAP in February 2008, the decision specified a formal revisit of the WSAP commencing in February 2010. The scheduled revisit was meant to ensure the opportunity for Metropolitan staff and the member agencies to re-evaluate the WSAP and recommend appropriate changes to the Board of Directors.

In April 2009, the Board voted to implement the WSAP for the first time. The WSAP was implemented at a Level 2 allocation level, and was in effect for the period of July 1, 2009, through June 30, 2010. Since implementation of the 2009/10 WSAP began in July 2009, a number of practical issues relating to the WSAP were identified by staff and the member agencies for further consideration during the 12-Month Review Process. Metropolitan staff engaged with the member agencies in a formal review of the WSAP from January through May 2010. During the review process the member agency managers participated in a series of six workshops. The focus of these workshops was to facilitate in-depth discussion on WSAP-related issues and lessons learned since the WSAP was implemented in July 2009. The proposed adjustments to the WSAP developed during the review process were adopted at the August 17, 2010 Board of Directors meeting[4].

The Three-Year Review Process

The Board action to adopt of the WSAP in February 2008 also directed staff to review the WSAP formula three years after the February 2008 adoption. February 2011 marked the three-year anniversary since the adoption of the WSAP. Similar to the 12-Month Review Process, the purpose of the Three-Year Review Process was to provide an opportunity for Metropolitan staff and the member agencies to re-evaluate the plan and recommend appropriate changes for board consideration.

Metropolitan staff met with the member agencies in a formal review of the WSAP from February through August 2011. Staff and member agency managers participated in a series of eleven workshops. Proposed adjustments to the WSAP developed during the process were adopted at the September 13, 2011 Board of Directors meeting.[5]

---

[4] A complete listing of member agency meetings and Board of Directors reporting activities is contained in Appendix C: 12-Month Review Process and Results.

[5] A complete listing of member agency meetings and Board of Directors reporting activities is contained in Appendix D: Three-Year Review Process and Results.

2014 Review Process

In 2014, California was challenged with a third year of severe drought.[6] Metropolitan managed its operations through significant use of regional storage reserves. It was anticipated that end of year total dry storage reserves would approach levels similar to those when the WSAP was last implemented in 2009.

Following discussion at the June 2014 Water Planning and Stewardship Committee, Metropolitan staff convened a member agency working group to revisit the WSAP. The purpose of the working group was to collaborate with member agencies to identify potential revisions to the WSAP in preparation for mandatory supply allocations in 2015. There were eight working group meetings and three discussions at the monthly Member Agency Managers' Meetings.

The process focused on three areas of the WSAP: the Base Period, the Allocation Formula, and the Allocation enforcement mechanism. Proposed adjustments to the WSAP developed during the process were adopted at the December 9, 2014 Board of Directors meeting. [7]

[6] The Governor of California proclaimed a State of Emergency due to drought conditions on January 17, 2014 and, on April 24, 2014 issued an Executive Order proclaiming a continued State of Emergency noting drought conditions have persisted for the last three years and authorizing adoption and implementation of emergency regulations.

[7] A complete listing of member agency meetings and Board of Directors reporting activities is contained in Appendix E: 2014 Review Process and Results.

Section 3: Review of Historical Shortage Plans[8]

The WSAP incorporates key features and principles from the following historical shortage allocation plans but will supersede them as the primary and overarching decision tool for water shortage allocation.

Interruptible Water Service Program

As part of the new rate structure implemented in 1981, Metropolitan's Board of Directors adopted the Interruptible Water Service Program (Interruptible Program) which was designed to address short-term shortages of imported supplies. Under the Interruptible Program, Metropolitan delivered water for particular types of use to its member agencies at a discounted rate. In return for this discounted rate, Metropolitan reserved the right to interrupt delivery of this Interruptible Program water so that available supplies could be used to meet municipal and industrial demands.

Incremental Interruption and Conservation Plan

The ability to interrupt specific deliveries was an important element of Metropolitan's strategy for addressing shortage conditions when it adopted the Incremental Interruption and Conservation Plan (IICP) in December 1990. Reductions in IICP deliveries were used in concert with specific objectives for conservation savings to meet needs during shortages. The IICP reduced Interruptible Service deliveries in stages and provided a pricing incentive program to insure that reasonable conservation measures were implemented.

1995 Drought Management Plan

The 1995 Drought Management Plan (DMP) was a water management and allocation strategy designed to match supply and demand in the event that available imported water supplies were less than projected demands. Adopted by the Metropolitan Board of Directors in November 1994, the 1995 DMP was a short-term plan designed to provide for the 1995 calendar year only. The primary objective of the 1995 DMP was to identify methods to avoid implementation of mandatory reductions. The 1995 DMP included various phases and a step-by-step strategy for evaluating supply and demand conditions and utilizing Metropolitan's available options, with the final phase being implementation of the revised IICP.

1999 Water Surplus and Drought Management Plan

Metropolitan staff began work on the Water Surplus and Drought Management (WSDM) Plan in March 1997 as part of the Integrated Water Resources Plan (IRP), which was adopted by Metropolitan's Board of Directors in January 1996. The IRP established regional water resource targets, identifying the need for developing resource management policy to guide annual operations. The WSDM Plan defined Metropolitan's resource management policy by establishing priorities for the use of regional resources to achieve the region's reliability goal identified in the IRP. In April 1999, Metropolitan's Board of Directors adopted the WSDM Plan.

[8] A summary of the key elements in the following allocation plan is found in Appendix F: Summary of Historical Shortage Plans.

The WSDM Plan also included a set of principles and considerations for staff to address when developing specific allocation methods. The WSDM Plan stated the following guiding principle to be followed in developing any future allocation scheme:

> *"Metropolitan will encourage storage of water during periods of surplus and work jointly with its member agencies to minimize the impacts of water shortages on the region's retail consumers and economy during periods of shortage."*[9]

This principle reflects a central desire for allocation methods that are both equitable and minimize regional hardship to retail water consumers. The specific considerations postulated by the WSDM Plan to accomplish this principle include the following:[10]

- The impact on retail customers and the economy
- Allowance for population and growth
- Change and/or loss of local supply
- Reclamation/Recycling
- Conservation
- Investment in local resources
- Participation in Metropolitan's interruptible programs
- Investment in Metropolitan's facilities.

Section 4: Water Supply Allocation Formula

Based on the guiding principle and considerations described in the WSDM Plan, Metropolitan staff and the member agencies developed a specific formula for allocating water supplies in times of shortage. The formula seeks to balance the impacts of a shortage at the retail level while maintaining equity on the wholesale level, and takes into account growth, local investments, changes in supply conditions and the demand hardening[11] aspects of non-potable recycled water use and the implementation of conservation savings programs. The formula, described below, is calculated in three steps: base period calculations, allocation year calculations, and supply allocation calculations.[12] The first two steps involve standard computations, while the third section contains specific methodology developed for this WSAP.

Base Period Calculations

The first step in calculating a water supply allocation is to estimate water supply and demand using a historical base period with established water supply and delivery data. The base period for each of the different categories of demand and supply is calculated using data from the fiscal years (July through June) ending 2013 and 2014.[13]

[9] WSDM Plan, p. 1. Emphasis added.
[10] WSDM Plan, p. 2.
[11] Demand hardening is the effect that occurs when all low-cost methods of decreasing overall water demand have been applied (e.g., low-flow toilets, water recycling) and the remaining options to further decrease demand become increasingly expensive and difficult to implement.
[12] Detailed operational elements of these objectives and a numerical example are discussed in Appendix G: Water Supply Allocation Formula Example.
[13] Exceptions to this methodology are noted in the descriptions of base period calculations.

Base Period Local Supplies: Local supplies for the base period are calculated using a two-year average of groundwater production, groundwater recovery, Los Angeles Aqueduct supply, surface water production, and other imported supplies. Non-potable recycling production is not included in this calculation due to its demand hardening effect.

Base Period Wholesale Demands: Demands on Metropolitan for the base period are calculated using a two-year average of firm purchases and in-lieu deliveries to long-term groundwater replenishment, conjunctive use, cyclic, and supplemental storage programs.

Base Period Retail Demands: Total retail-level municipal and industrial (M&I) demands for the base period are calculated by adding the Base Period Wholesale Demands and the Base Period Local Supplies. This estimates an average total demand for water from each agency.

Base Period Mandatory Conservation Credit: Metropolitan allows a consultation process that enables member agencies to describe mandatory water use restrictions and/or rationing restrictions that were in place within their service areas during the Base Period. Restrictions may vary among agencies but include restricted water uses, fines, and water budget or penalty based rate structures that are enacted by the governing body of the member agency or retail agency. Following the consultation process, Metropolitan staff will recommend adjustments based on evidence of reduced GPCD. To qualify for an adjustment, GPCD reductions would have to be observed that are beyond those expected from the agency's ongoing conservation efforts and trends.

Allocation Year Calculations

The next step in calculating the water supply allocation is estimating water needs in the allocation year. This is done by adjusting the base period estimates of retail demand for population or economic growth and changes in local supplies.

Allocation Year Retail Demands: Total retail M&I demands for the allocation year are calculated by adjusting the Base Period Retail Demands for baseline inflation and growth.

Baseline Inflation Adjustment: Baseline inflation occurs when non-potable recycling or conservation is developed after the Base Period. The development of these supplies reduces actual demands for water in the Allocation Year. Because non-potable-recycling and conservation are excluded from the WSAP formula, the actual need for water in the Allocation year is overestimated. The Baseline Inflation Adjustment removes increases in non-potable recycling and conservation annually from the Base Period forward to better reflect the true need for water in the Allocation Year.

Growth Adjustment: The growth adjustment is calculated using the estimated actual annual rate of population growth at the county level, as generated by the California Department of Finance, whenever possible. For years without complete data, the growth rate is calculated using an average of the three most recent years available. Growth will be allocated based on historical per capita water use during the Base Period, with a cap equal to Metropolitan's IRP Target for Water Use Efficiency. For allocation years up to and including 2014, the cap will be 163 GPCD, and for allocation years 2015-2020 the cap will reduce linearly from 163 to 145 GPCD. On an appeals basis, member agencies may request that their adjustment be calculated using member agency level population growth. A weighted combination of actual population and actual employment growth rates may also be requested.

Allocation Year Local Supplies: Allocation Year Local Supplies include groundwater production, groundwater recovery, Los Angeles Aqueduct supply, surface water production, seawater desalination, and other imported supplies. Estimates of Allocation Year Local Supplies are provided by the member agencies upon implementation of a WSAP. If estimates are not provided, Metropolitan will use the sum of the Base Period Local Supplies and Base Period In-Lieu Deliveries as a default. Agencies may provide updated estimates at any time during the Allocation Year to more accurately reflect their demand for Metropolitan supplies.

Extraordinary Supplies: Under the WSAP formula, local supply production in the Allocation Year can either be designated as a "planned" supply, or as an "extraordinary" supply.[14] This is an important designation for a member agency because the two types of supplies are accounted for differently in the WSAP formula. Local supplies classified at Extraordinary Supply are only partially included (scaled depending on the WSAP Level) as local supplies. This has the effect of providing significantly more benefit to the member agency in terms of total water supply that is available to the retail customer.[15]

Allocation Year Wholesale Demands: Demands on Metropolitan for the allocation year are calculated by subtracting the Allocation Year Local Supplies from the Allocation Year Retail Demands.

Water Supply Allocation Calculations

The final step is calculating the water supply allocation for each member agency based on the allocation year water needs identified in Step 2. The following table displays the elements that form the basis for calculating the supply allocation. Each element and its application in the allocation formula are discussed below.

Table 1: Shortage Allocation Index

(a) Regional Shortage Level	(b) Wholesale Minimum Percentage	(c) Maximum Retail Impact Adjustment Percentage
1	92.5%	2.5%
2	85.0%	5.0%
3	77.5%	7.5%
4	70.0%	10.0%

[14] Appendix H: Board Policy Principles on Determining the Status of Extraordinary Supply lists the key Board principles used in determining if a supply qualifies as an Extraordinary Supply.

[15] See Appendix G: Water Supply Allocation Formula Example for specific allocation formulae.

5	62.5%	12.5%
6	55.0%	15.0%
7	47.5%	17.5%
8	40.0%	20.0%
9	32.5%	22.5%
10	25.0%	25.0%

Regional Shortage Level: The WSAP formula allocates shortages of Metropolitan supplies over ten levels.

Wholesale Minimum Allocation: The Wholesale Minimum Allocation ensures a minimum level of Metropolitan supplied wholesale water service to each member agency.

Maximum Retail Impact Adjustment: The purpose of this adjustment is to ensure that agencies with a high level of dependence on Metropolitan do not experience disparate shortages at the retail level compared to other agencies when faced with a reduction in wholesale water supplies. The Maximum Retail Impact Percentage is prorated on a linear scale based on each member agency's dependence on Metropolitan at the retail level. This percentage is then multiplied by the agency's Allocation Year Wholesale Demand to determine an additional allocation.

Conservation Demand Hardening Credit: The Conservation Demand Hardening Credit addresses the increased difficulty in achieving additional water savings at the retail level that comes as a result of successful implementation of water conserving devices and conservation savings programs. To estimate conservation savings, each member agency will establish a historical baseline Gallons Per Person Per Day (GPCD) calculated in a manner consistent with California Senate Bill SBx7-7.[16] Reductions from the baseline GPCD to the Allocation Year are used to calculate the equivalent conservation savings in acre-feet. The Conservation Demand Hardening Credit is based on an initial 10 percent of the GPCD-based Conservation savings plus an additional 5 percent for each level of Regional Shortage set by the Board during implementation of the WSAP. The credit will also be adjusted for:

- The overall percentage reduction in retail water demand
- The member agency's dependence on Metropolitan

The credit is calculated using the following formula:

Conservation Demand Harding Credit = Conservation Savings x (10% + Regional Shortage Level Percentage) x (1 +((Baseline GPCD – Allocation Year GPCD)/Baseline GCPD)) x Dependence on MWD Percentage

[16] California Department of Water Resources, February 2011, "Methodologies for Calculating Baseline and Compliance Urban Per Capita Water Use. Available at: http://www.water.ca.gov/wateruseefficiency/sb7/docs/MethodologiesCalculatingBaseline_Final_03_01_2011.pdf

This provides a base demand hardening credit equal to 10 percent of conservation savings and increases the credit as deeper shortages occur, which is when conservation demand hardening has a bigger impact on the retail consumer. The credit also increases based on the percentage of an agency's demand that was reduced through conservation. This accounts for increased hardening that occurs as increasing amounts of conservation are implemented. Lastly, the credit is scaled to the member agency's dependence on Metropolitan to ensure that credits are being applied to the proportion of water demand that is being affected by reductions in Metropolitan supply.

Minimum Per-Capita Water Use Credit: This adjustment creates a minimum per capita water use threshold. Member agencies' retail-level water use is compared to two different thresholds. The proposed minimum thresholds are based upon compliance guidelines established under Senate Bill X7-7.

- 100 GPCD total water use
- 55 GPCD residential water use

Agencies that fall below either threshold under the WSAP will receive additional allocation from Metropolitan to bring them up to the minimum GPCD water use level. If an agency qualifies under both thresholds, the one resulting in the maximum allocation adjustment will be given.[17] To qualify for this credit, member agencies must provide documentation of the total agency level population and the percent of retail level demands that are residential; no appeal is necessary.

Total WSAP Allocation: The allocation to an agency for its M&I retail demand is the sum of the Wholesale Minimum Allocation, the Retail Impact Adjustment, the Conservation Demand Hardening Credit, and the Minimum Per-Capita Water Use Credit.[18]

Total Metropolitan Supply Allocations: In addition to the WSAP Allocation described above, agencies may also receive separate allocations of supplies for and seawater barrier and groundwater replenishment demands. Allocations of supplies to meet seawater barrier demands are to be determined by the Board of Directors independently but in conjunction with the WSAP. Separating the seawater barrier allocation from the WSAP allocation allows the Board to consider actual barrier requirements in the Allocation Year and address the demand hardening issues associated with cutting seawater barrier deliveries. According to the principles outlined for allocating seawater barrier demands, allocations should be no deeper than the WSAP Wholesale Minimum Percentage implemented at that time.

The WSAP also provides a limited allocation for drought-impacted groundwater basins based on the following framework:[19]

[17] See Appendix J: Per Capita Water Use Minimum Example for specific minimum per-capita water use credit formulae and example.
[18] See Appendix G: Water Supply Allocation Formula Example for specific allocation formulae.
[19] See Appendix L: Groundwater Replenishment Allocation for more information.

1. Metropolitan staff will hold a consultation with the requesting member agency and the appropriate groundwater basin manager to document whether the basin is in one of the following conditions:
    a. Groundwater basin overdraft conditions that will result in water levels being outside normal operating ranges during the WSAP allocation period; or
    b. Violations of groundwater basin water quality and/or regulatory parameters that would occur without imported deliveries
2. An allocation is provided based on the verified need for groundwater replenishment. The allocation would start with a member agency's ten-year average purchases of imported groundwater replenishment supplies (excluding years in which deliveries were curtailed). The amount would then be reduced by the declared WSAP Regional Shortage Level.

Section 5: WSAP Implementation

The WSAP will take effect if a regional shortage is declared by the Board of Directors. The following implementation elements are necessary for administering the WSAP during a time of shortage. These elements cover the processes needed to declare a regional shortage level as well as provide information pertaining to the allocation surcharge.

Allocation Period

The allocation period covers twelve consecutive months, from July of a given year through the following June. This period was selected to minimize the impacts of varying State Water Project (SWP) allocations and to provide member agencies with sufficient time to implement their outreach strategies and rate modifications.

Setting the Regional Shortage Level

Metropolitan staff is responsible for recommending a Regional Shortage Level for the Board of Directors' consideration. The recommendation shall be based on water supply availability, and the implementation of Metropolitan's water management actions as outlined in the WSDM Plan. Metropolitan staff will keep the Board of Directors apprised to the status of water supply conditions and management actions through monthly reports to the Water Planning and Stewardship Committee. To further facilitate staff in the development of a recommended regional shortage level, member agency requests for local supply adjustments shall be submitted by April 1st.

Metropolitan's Board of Directors, through the Water Planning and Stewardship Committee, is responsible for approving the final Regional Shortage Level at its April meeting. By the April meeting, the majority of the winter snowfall accumulation period will have passed and will allow staff to make an allocation based on more stable water supply estimates. Barring unforeseen large-scale circumstances, the Regional Shortage Level will be set for the entire allocation period, which will provide the member agencies an established water supply level for their planning.

Exit Strategy

While the Board ultimately has discretion to implement or lift and allocation at any point of time during the year; the WSAP includes a two-part exit strategy that is meant to streamline the WSAP implementation decision making process.

- If the Board decides to implement the WSAP, then any current WSAP allocation would remain in place until the end of the Allocation Year.
- If the Board decides not to implement the WSAP, then any current WSAP allocation would be terminated concurrent with the Board decision.

Allocation Appeals Process

An appeals process is necessary for the administration of any changes or corrections to an agency's allocation. Metropolitan's General Manager will designate, subsequent to a declaration of an allocation by the Board of Directors, an Appeals Liaison as the official point of contact for all information and inquiries regarding appeals. All member agency General Managers will be notified in writing of the name and contact information of the Appeals Liaison. Only appeals that are made through the Appeals Liaison and in accordance with the provisions outlined in Appendix N: Allocation Appeals Process will be evaluated. Basis for appeals claims can include but are not limited to:

- Adjusting erroneous historical data used in base period calculations
- Adjusting for population growth rates
- Determining if a local supply qualifies as Extraordinary Supply

Additional details and a checklist for the appeals process are available in Appendix N: Allocation Appeals Process and Appendix O: Appeals Submittal Checklist.

Allocation Surcharge

Member agency allocations are supported by an Allocation Surcharge. The Allocation Surcharge is charged to water use above the Member Agency allocation and is charged in addition to Metropolitan's standard rates for water service. Allocation Surcharges will only be assessed to the extent that an agency's total annual usage exceeds its total annual allocation. Any revenues collected through the Allocation Surcharge will be applied towards Metropolitan's Water Management Fund, which is used to in part to fund expenditures in dry-year conservation. No billing or assessment of allocation surcharges rates will take place until the end of the twelve-month allocation period.

Allocation Surcharge: The application of the Allocation Surcharge structure is a two tier structure that provides a lower level of Allocation Surcharge for minor overuse of allocations and a higher level of Allocation Surcharge for major overuse of allocations. The structure and applicable Allocation Surcharges are listed in Table 2.

Table 2: Allocation Surcharge			
Water Use	**Base Water Rate**[20]	**Allocation Surcharge**[21]	**Total Rate**
100% of Allocation	Tier 1	0	Tier 1
Between 100% and 115%	Tier 1	$1,480	Tier 1 + ($1,480)
Greater than 115%	Tier 1	$2,960	Tier 1 + ($2,960)

Qualifying Income-Based Rate Allocation Surcharge Adjustment:[22] Any Allocation Surcharges incurred by a member agency under the WSAP will be adjusted to reflect the extent to which retail customers within a member agency's service area are served under a "lifeline" or similar qualified discounted rate program based on income or ability to pay ("Income-Based Rate").

Any member agency who is assessed Allocation Surcharges under the WSAP may submit an acre-foot equivalent of water used by retail customers served under a qualifying Income-Based Rate.[23] This amount of water use would be multiplied by the percentage of retail-level reduction in allocation year demand necessary for that member agency to avoid exceeding its WSAP allocation. The monetary amounts resulting from these acre feet are subtracted from the total monetary amounts incurred by an agency for exceeding its allocation. In the case that the monetary amounts associated with the Income-Based Rate are greater than the total Allocation Surcharges an agency incurs, no Allocation Surcharges will be incurred. The end result of this adjustment is that the member agency will not be subject to Allocation Surcharges for the use of water by their retail customers served under a qualifying Income-Based Rate.

Growth Rate Allocation Surcharge Adjustment": In recognition of member agency differences in geography and climate, a Growth Rate Allocation Surcharge Adjustment will be given to any agency that exceeds its WSAP Allocation. The Allocation Surcharge reduction will be based on the difference in acre-feet between the Growth Adjustment applied at Metropolitan's IRP planning goal rate, and the greater of the following:

- The IRP planning goal rate adjusted for the member agency's ETo, or
- The member agency's certified and documented 20x2020 targeted GPCD

If both of these alternatives result in a lower growth adjustment than the IRP planning goal, no Allocation Surcharge reduction will be made.

[20] The base water rate shall be the applicable water rate for the water being purchased. In most cases, it will be the Tier 1 rate (plus Treatment Surcharge for treated water deliveries). However, it is possible that the water being purchased would be in the amount that would put an agency beyond its Tier 1 limit. In that case, the base water rate will be the Tier 2 rate (plus Treatment Surcharge for treated water deliveries).
[21] Allocation Surcharge is applied to water use in excess of an agency's WSAP allocation.
[22] See Appendix K: Qualifying Income-Based Rate Allocation Surcharge Adjustment Example for specific penalty adjustment formulae and example.
[23] Appropriate documentation and certification will be required.

Tracking and Reporting

Subsequent to a declared regional shortage by the Board of Directors, Metropolitan staff will produce monthly reports of each member agency's water use compared to its allocations based on monthly delivery patterns to be submitted by the member agency. In order to produce these reports, member agencies are requested to submit their local supply use on a monthly basis and certify end of allocation year local supply use. These reports and comparisons are to be used for the purposes of tracking and communicating potential underage/overage of an agency's annual allocations.

Key Dates for Water Supply Allocation Implementation

The timeline for implementation of an allocation is shown in Table 3. A brief description of this timeline follows:

January to March: Water Surplus and Drought Management reporting occurs at Metropolitan's Water Planning and Stewardship Committee meetings. These reports will provide updated information on storage reserve levels and projected supply and demand conditions.

April: Member agencies report their projected local supplies for the coming allocation year. This information is incorporated in staff analysis of storage reserves and projected supply and demand conditions in order to provide an allocation recommendation to the Board. Metropolitan's Board will consider whether an allocation is needed. A declaration of an allocation will include the level of allocation to be in effect for the allocation year. Likewise, member agencies will report their projected demands and local supplies needed to meet seawater barrier and groundwater replenishment requirements for the allocation year. Metropolitan's Board will consider whether allocations for seawater barrier demands and groundwater replenishment demands are needed independently from the WSAP allocation decision.**July 1st**: If the Board declared an allocation in April, then it will be effective starting July 1st. The allocation level will be held through June 30th, barring unforeseen circumstances. Member agencies will now be requested to submit their local supply use on a monthly basis and certify end of allocation year local supply use. Local production data must be reported to Metropolitan by the end of the month following the month of use (use in July must be reported by the end of August). This information will be combined with Metropolitan sales information in order to track retail water use throughout Metropolitan's service area. Each month Metropolitan will report on member agency water sales compared to their allocation amounts.

June 30th: The allocation year is complete.

July: Member agency local supplies must be certified for the month of June, the last month of the previous allocation year.

August: Metropolitan will calculate each member agency's total potable water use based on local supply certifications and actual sales data for the allocation year of July through June. Allocation surcharges will be assessed for usage above a given member agency's final adjusted allocation (reflecting the actual local supply and imported water use that occurred in the allocation year).

Appendix C: 12-Month Review Process and Results

January 2010

- WSAP 12-Month Review Process workshop #1
    - Focused discussion of WSAP issues identified by Metropolitan staff and by member agencies since the July 2009 implementation began.

February 2010

- WSAP 12-Month Review Process workshop #2
    - Continuation of focused discussion
- WSAP 12-Month Review Process workshop #3
    - Continuation of focused discussion

March 2010

- WSAP 12-Month Review Process workshop #4
    - Continuation of focused discussion
- MWD Board of Directors information item
    - Review of potential modifications to the WSAP definition of Extraordinary Supply

April 2010

- WSAP 12-Month Review Process workshop #5
    - Recap of identified issues and discussion of Metropolitan staff proposals for adjustments to the WSAP
- Member Agency Managers Meeting
    - Update on the 12-Month Review Process
- WSAP 12-Month Review Process workshop #6
    - Discussion of WSAP issues related to groundwater replenishment
- Member Agency Managers conference call
    - Clarification of WSAP definition for Extraordinary Supply

May 2010

- Member Agency Managers Meeting
    - Discussion of proposed Extraordinary Supply policy principles and WSAP Local Supply certification process.
- Member Agency Managers conference call
    - Discussion of proposed Extraordinary Supply policy principles

June 2010

- MWD Board of Directors action item

July 2010

- MWD Board of Directors information item
    - Review of proposed adjustments to the WSAP developed in the 12-Month Review Process

August 2010

- MWD Board of Directors action item

Resulting Changes

- Removed references to Gains and Losses of Local Supply
  - Removed references in the WSAP to "gains and losses of local supplies" in order to better facilitate the accounting of historical base year and allocation year local supplies. This change did not affect the WSAP formula or allocations.
- Removed references to the Regional Shortage Percentage
  - Removed references to the "Regional Shortage Percentage" in the WSAP to reduce unintended confusion between calculation factors and shortage amounts. This change did not affect the WSAP formula or allocations.
- Included the Retail Impact Adjustment in all shortage levels
  - Included the Retail Impact Adjustment for Regional Shortage Levels 1 and 2. This change results in additional allocations to Metropolitan-dependent agencies under Level 1 and Level 2 regional shortages.
- Revised the accounting of Extraordinary Supplies
  - Revised the methodology for accounting of Extraordinary Supply in the WSAP formula by:
    - Removing the Base Period Local Supply threshold provision,
    - Removing the sliding-scale sharing mechanism from the formula, and
    - Including the full amount of the Extraordinary Supply in the calculation of the Retail Impact Adjustment.
- Included a Minimum Per Capita Water Use Threshold
  - Developed a minimum water use credit based on two GPCD water use thresholds. Member agencies would receive additional Metropolitan allocation for an acre-foot equivalent of GPCD below the minimum threshold. Member agency water use, on a gallon per capita per day (GPCD) basis, is compared to the following minimum thresholds established under Senate Bill X7-7 (Water Conservation Act of 2009)
    - 100 GPCD total use or
    - 55 GPCD residential indoor use
- Excluded Seawater Barrier from the WSAP Formula
  - Excluded seawater barrier supplies from the WSAP Base Period and Allocation Year local supply calculations. This allows the Board to determine allocations for seawater barrier demands separately from the WSAP.

Appendix D: Three-Year Review Process and Results

February 2011

- WSAP 3-Year Review Process workshop #1
  - Review of the existing WSAP policy formula; review of the process timeline; and focused discussion of WSAP issues identified by Metropolitan staff and by member agencies since the WSAP's adoption in February 2008

March 2011

- WSAP 3-Year Review Process workshop #2
  - Discussion of issues related to local supplies and baseline inflation due to adjustments for recycling in the WSAP formula
- WSAP 3-Year Review Process workshop #3
  - Continuation of prior workshop

April 2011

- WSAP 3-Year Review Process workshop #4
  - Discussion of issues and alternatives related to base period selection and baseline inflation in the WSAP formula
- WSAP 3-Year Review Process workshop #5
  - Discussion of recommendations to address baseline inflation in the WSAP formula

May 2011

- WSAP 3-Year Review Process workshop #6
  - Discussion of issues and alternatives for the growth adjustment methodology in the WSAP formula
- WSAP 3-Year Review Process workshop #7
  - Continuation of prior workshop

June 2011

- WSAP 3-Year Review Process workshop #8
  - Continuation of prior workshop, discussion of WSAP implementation exit strategy
- WSAP 3-Year Review Process workshop #9
  - Continuation of exit strategy discussion, discussion of baseline inflation due to conservation and related conservation demand hardening issues

July 2011

- WSAP 3-Year Review Process workshop #9
  - Continued discussion of baseline inflation and conservation issues, and discussion of sharing allocations between agencies with common local resources

August 2011

- WSAP 3-Year Review Process workshop #10
  - Discussion of WSAP Allocation Year timing vs. Tier 1-Tier 2 rate cycle timing, discussion of approaches for encouraging completion of WSAP local supply certifications
- Review WSAP at Member Agency Managers Meeting
  - Discussion of proposed WSAP adjustments to address baseline inflation issues, revise the growth adjustment methodology, and establish a WSAP exit strategy

September 2011

- MWD Board of Directors action item

Resulting Changes

- Baseline Inflation Adjustment
    - Removed non-potable recycling and conservation from the WSAP baseline
        - Increases in recycling and conservation will be subtracted annually from the Base Period forward
        - The annual population growth rate will be applied after deducting the annual increases in recycling and conservation
        - If an agency ends up in allocation penalty, a penalty reduction will be applied in an amount equal to the Code-Based and rate Structure conservation savings that were removed from the WSAP baseline
- Changed the Growth Adjustment methodology
    - Growth will be allocated at historical per capita rate capped at the 2010 Integrated Water Resource Plan (IRP) Target for Water Use Efficiency
        - For years up to and including 2014, the cap will be 163 GPCD
        - For years 2015-2020, the cap will reduce linearly from 163 to 145 GPCD
    - If an agency exceeds its allocation, a penalty reduction will be applied based on either:
        - The differential Evapotranspiration (ETo) of its service area compared to the MWD average, or
        - Certified and documented 20 x 2020 targeted GPCD
- Exit Strategy
    - Clarified the course of action for an existing WSAP allocation when Metropolitan's Board makes a declaration decision for the following WSAP year
        - If there is an allocation for the next year, then the current allocation stays in place
        - If there is no allocation for the next year, then the current allocation is lifted concurrent with the April decision

Appendix E: 2014 Review Process and Results

July 2014

- WSAP Workgroup Meeting #1
    - First meeting of the 2014 WSAP Review process; review of the existing WSAP policy and formula; review of the process timeline; began discussion of issues related to base period selection
- WSAP Workgroup Meeting #2
    - Discussion of base period selection

August 2014

- WSAP Workgroup Meeting #3
    - Continuation of prior workshop discussion; comparison of base period alternatives

September 2014

- WSAP Workgroup Meeting #4
    - Discussion of a base period proposal; discussion of replenishment issues in the WSAP; discussion of 2015 water supply scenarios
- Review WSAP at Member Agency Managers Meeting
    - Review of WSAP workgroup process; discussion on issues related to base period, demand hardening, and local resources development
- WSAP Workgroup Meeting #5
    - Review of base period recommendation; discussion of issues regarding agencies in mandatory conservation during a base period; discussion on replenishment in the WSAP

October 2014

- WSAP Workgroup Meeting #6
    - Continuation of prior workshop discussion; discussion of alternative methods for conservation demand hardening credit; discussion of new and existing local supplies
- Review WSAP at Member Agency Managers Meeting
    - Review of WSAP workgroup process; discussion of issues related to base period and demand hardening

November 2014

- WSAP Workgroup Meeting #7
    - Review and discussion of issues and potential methods for base period selection and adjustment, replenishment allocation, and conservation demand hardening credit; review of estimated effects of potential WSAP changes at the regional level
- WSAP Workgroup Meeting #8
    - Review of proposed recommendations for the WSAP based on workgroup discussion
- Review WSAP at Member Agency Managers Meeting
    - Review of proposed recommendations for the WSAP based on workgroup discussion

Resulting Changes

- Base Period Update to FY2013 and FY2014
  - Changed the WSAP Base Period from calendar years 2004-2006 to fiscal years ending July 2013 and 2014
  - Mandatory Conservation Adjustment
    - Agencies with mandatory conservation in effect during the base period (FY 2013 and/or FY 2014) may qualify for a demand hardening adjustment, adjustment is subject to a consultation process that includes consideration historical demand and GPCD information

- Modify Conservation Demand Hardening Credit
  - Replaced device calculation-based estimates of conservation savings with a GPCD-based method
    - Conservation savings are calculated by comparing GPCD from a historical baseline to the Allocation Year; the difference is converted to acre-feet using the Allocation Year population.
      - Baseline GCPD is 10-year average ending between 2004 and 2010, with gross water, using gross water use minus non-potable recycled water production and documented historical population
  - Replaced formula for calculating the credit for each Regional Shortage Level
  - Conservation Demand hardening credit will be based on an initial 10 percent of GPCD-based conservation savings plus an additional 5 percent for each level of Regional Shortage; the credit will also be adjusted for the overall percentage reduction in retail water demand and the member agency's dependence on Metropolitan.
- Allocation Surcharge
  - Replaced the WSAP Penalty Rate with an Allocation Surcharge based on the estimated cost of Turf Replacement conservation programs

Appendix F: Summary of Historical Shortage Plans

These five elements incorporated into the WSAP have, in four out of five instances, been used in previous shortage plans. Both the IICP and the 1995 DMP used a historical base period calculation, adjusted for growth, made local supply adjustments, and used conservation hardening credits in their formulations. The retail impact adjustment is the only feature of the WSAP that has not been used historically.

Table 5: Historical Shortage Plan Overview

Plan Element	1991 IICP	1995 DMP	WSAP
Historical Base Period	√	√	√
Growth Adjustment	√	√	√
Local Supply Adjustment	√	√	√
Conservation Hardening Credit	√	√	√
Retail Impact Adjustment			√

Appendix G: Water Supply Allocation Formula Example

The following example gives a step-by-step description of how the formula would be used to calculate an allocation of Metropolitan supplies for a hypothetical member agency. All numbers are hypothetical for the purpose of the example and do not reflect any specific member agency.

Step 1: Calculate Base Period Retail Demand

Base Period Local Supplies: Calculated using a two-year average of groundwater (gw), groundwater recovery (gwr), Los Angeles Aqueduct supply (laa), surface water (sw), seawater desalination (sd), and other non-Metropolitan imported supplies (os). For the purpose of this example, assume that the two year average is 59,000 af.

$$[(gw1+gwr1+laa1+sw1+sd1+os1) + (gw2+gwr2+laa2+sw2+sd2+os2)] \div 2 = 59{,}000 \text{ af}$$

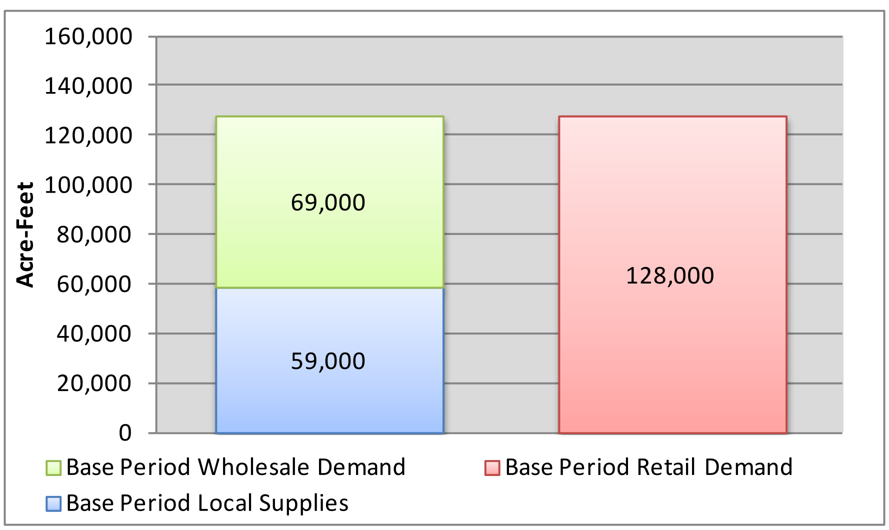
Base Period Wholesale Demands: Calculated using the same two-year time period as the Base Period Local Supplies. The Base Period Wholesale Demands include firm purchases (fp) and in-lieu deliveries to long-term groundwater replenishment (il), conjunctive use (cup), cyclic (cyc), and supplemental storage programs (ss). For the purpose of this example, assume that the two year average is 69,000 af.

$$[(fp^1++il^1+cup^1+cyc^1+ss^1) + (fp^2+il^2+cup^2+cyc^2+ss^2)] \div 2 = 69{,}000 \text{ af}$$

Base Period Retail Demands: Calculated as the sum of the Base Period Local Supplies and Base Period Wholesale Demand.

$$59{,}000 + 69{,}000 = 128{,}000 \text{ af}$$

Figure 1: Base Period Retail Demand Calculation



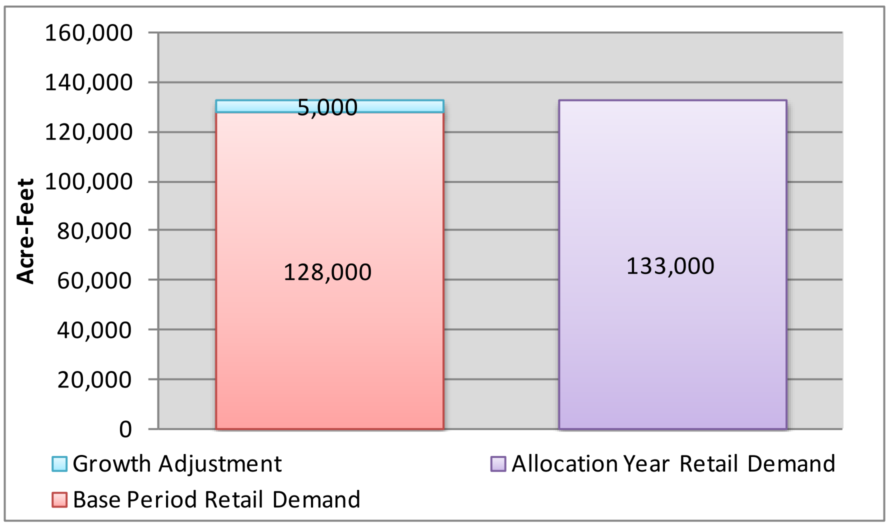
Calculate Adjustment for Base Period Mandatory Rationing (if applicable): The hypothetical agency used in this example is assumed not to qualify for the Base Period Mandatory Rationing Adjustment. A detailed discussion of the adjustment methodology can be found in Appendix I: Base Period Rationing Adjustment Example.

Step 2: Calculate Allocation Year Retail Demand

Allocation Year Retail Demand: Calculated by adjusting the Base Period Retail Demand for any baseline inflation and growth that occurred since the Base Period.

128,000 af + 5,000 af (net adjustment to retail demand) = 133,000 af

Figure 2: Allocation Year Retail Demand Calculation



Step 3: Calculate Allocation Year Wholesale Demand

Allocation Year Local Supplies: Estimates of Allocation Year Local Supplies are provided by the member agencies upon implementation of a WSAP. If estimates are not provided, Metropolitan will use the sum of the Base Period Local Supplies and Base Period In-Lieu Deliveries as a default. Agencies may provide updated estimates at any time during the Allocation Year to more accurately reflect their demand for Metropolitan supplies. For this example assume that the Allocation Year Local Supplies total 65,000 acre-feet.

Allocation Year Local Supplies = 65,000 af

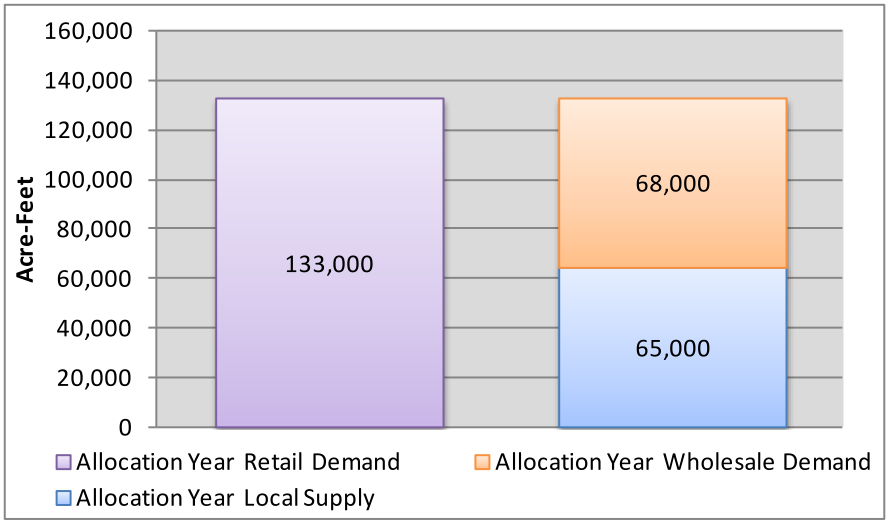
For this example assume also that this agency has an additional 5,000 acre-feet of supplies that meet the determinations for Extraordinary Supply. These supplies are withheld from the allocation formula except for in calculating the Retail Impact Adjustment Allocation.

Extraordinary Local Supplies = 5,000 af

Allocation Year Wholesale Demands: Calculated by subtracting the Allocation Year Local Supplies (65,000 af) from the Allocation Year Retail Demands (133,000 af).

133,000 af - 65,000 af = 68,000 af

Figure 3: Allocation Year Wholesale Demand Calculation



Step 4: Calculate the Wholesale Minimum Allocation

Wholesale Minimum Percentage: Calculate from Table 1 for Regional Shortage Level 4.

Table 1: Shortage Allocation Index		
(a) Regional Shortage Level	(b) Wholesale Minimum Percentage	(c) Maximum Retail Impact Adjustment Percentage
4	70.0%	10.0%

Wholesale Minimum Allocation: Calculated by multiplying the agency's Allocation Year Wholesale Demand (68,000 af) by the Wholesale Minimum Percentage (70%) from the Table 1 for Regional Shortage Level 4.

68,000 af * 70% = 47,600 af

Step 5: Calculate the Retail Impact Adjustment Allocation

Maximum Retail Impact Adjustment Percentage: Calculate from Table 1 for Regional Shortage Level 4.

Retail Impact Adjustment Allocation: Calculated first by determining the agency's dependence on Metropolitan by dividing the Allocation Year Wholesale Demand (68,000 af) minus the Extraordinary Supply (5,000 af) by the Allocation Year Retail Demand (133,000 af) and multiplying by 100.

[(68,000 af - 5,000 af)/ 133,000 af] * 100 = 47%

Next, this percentage dependence on Metropolitan (47%) is multiplied by the Maximum Retail Impact Percentage for Shortage Level 4 (10%).

47% * 10% = 4.7%

This percentage is now multiplied by the Allocation Year Wholesale Demand (68,000 af) for the Retail Impact Adjustment Allocation.

68,000 af * 4.7% = 3,221 af

Step 7: Calculate the Conservation Demand Hardening Adjustment

Calculate Baseline GPCD: To estimate conservation savings, each member agency will establish a historical baseline GPCD calculated in a manner consistent with California Senate Bill SBx7-7, using a 10 or 15-year average ending between 2004 and 2010, using gross water use minus non-potable recycle water production and documented historical population. For this example assume that the Baseline GPCD is 154 GPCD

Baseline GPCD = 154 GPCD

Calculate Allocation Year GPCD: Next, calculate the allocation year GPCD by converting the Allocation Year Retail Demand to GPCD and dividing by the Allocation Year Population from the WSAP. For this example the Allocation Year Retail Demand is 133,000 AF (see Step 2 above) and assume the Allocation Year Population is 905,000 persons. The resulting GPCD is 131 GPCD.

Allocation Year GPCD = 133,000 af/year * 325,851 gallons/af ÷ 365 days/year ÷ 905,000 persons = 131 GPCD

Calculate Reduction in GPCD: Subtract Allocation Year GPCD from Baseline GPCD to determine the GPCD Reduction.

GPCD Reduction = 154 GPCD – 131 GPCD = 23 GPCD

Calculate Conservation Savings: Convert the GPCD Reduction to the equivalent annual conservation savings in acre-feet, using the Allocation Year Population.

$$\text{Conservation Savings} = \frac{\text{((GPCD Reduction) x 365 days/yr x Population)}}{\text{325,851 gallons/af}}$$

Conservation Savings = 23 x 365 x 905,000 ÷ 325,851 = 23,316 af

Multiply by Regional Shortage Level Percentage: Multiply the Conservation Savings by 10 percent plus an additional 5 percent for each level of Regional Shortage (see Step 4 above). This example assumes a Regional Shortage Level of 4. This scales the hardening credit by the level of regional shortage, thereby increasing the credit as deeper shortages occur when demand hardening has a larger impact on the retail consumer.

23,316 af x (10% + (4 x 5%)) = 6,995 af

Multiply by Conservation Savings Percentage: Next, multiply by the percentage of an agency's demand that was reduced through conservation. This scales the hardening by the total percentage reduction to recognize that increased hardening occurs as increasing amounts of conservation are implemented.

Conservation Savings Percentage = 1 + ((Baseline GPCD – Allocation Year GPCD)/Baseline GPCD)

Conservation Savings Percentage = 1+ ((154 GPCD – 131 GPCD)/154 GPCD) = 115%

6,995 af x 115% = 8,044 af

Multiply by Dependence on MWD: Next, multiply by the agency's percentage dependence on MWD as shown in Step 5 above. This scales the credit to the member agency's dependence on MWD to ensure that credits are being applied to the proportion of water demand that is being affected by reductions in MWD's supply. For this example, dependence on MWD is 47%.

8.044 af x 47% = 3,781 af

Summary: The Conservation Demand Hardening Adjustment calculation is summarized by the following formula:

Conservation Demand Hardening Adjustment = Conservation Savings x (10% + Regional Shortage Level %) x (1+Conservation%) x Dependence on MWD %

Conservation Demand Hardening Adjustment = 23,316 af x (10% + (4 x 5%)) x (115%) x (47%) = 3,781 af

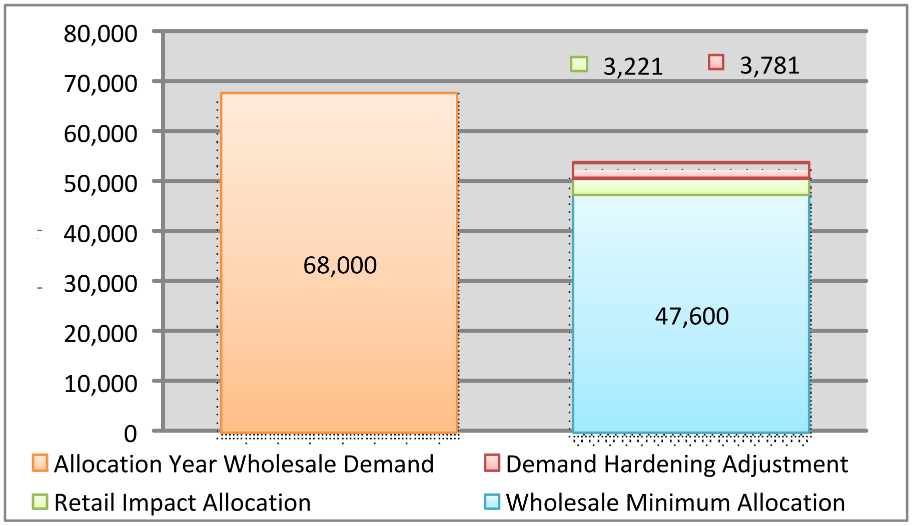
Step 8: Calculate the Low Per-Capita Adjustment Allocation: The hypothetical agency used in this example is assumed not to qualify for the Low Per-Capita Adjustment. A detailed discussion and example of the Low Per-Capita Adjustment calculation can be found in Appendix J: Per Capita Water Use Minimum Example.

Step 9: Calculate the total WSAP Allocation

WSAP Allocation: Calculated by adding the Wholesale Minimum Allocation (47,600 af), the Maximum Retail Impact Adjustment (3,221 af), the Demand Hardening Adjustment (3,781 af), and the Low Per-Capita Adjustment (0 af).

47,600 af + 3,221 af + 3,781 af + 0 af = 54,602 af

Figure 4: WSAP Allocation Regional Shortage Level 4



Step 10: Calculate total retail level reliability

Retail level reliability: Calculated by adding the WSAP Allocation (54,602 af), the Allocation Year Local Supply (65,000 af) and the Extraordinary Local Supply (5,000 af) and dividing by the Allocation Year Retail Demand (133,000 af).

(54,602 af + 65,000 af + 5,000 af) ÷ 133,000 af = 93.7%

Total Metropolitan Supply Allocations: In addition to the WSAP Allocation described above, agencies may also receive separate allocations of supplies for groundwater replenishment and seawater barrier demands. More information on the groundwater replenishment allocation is located in Appendix L: Groundwater Replenishment Allocation.

Appendix H: Board Policy Principles on Determining the Status of Extraordinary Supply

At the June 8, 2010 Water Planning and Stewardship Committee meeting Metropolitan's Board of Directors adopted the following policy principles to guide staff in determining the Extraordinary Supply status of future member agency supply programs.

No Negative Impacts to Other Member Agencies

A potential Extraordinary Supply for a member agency should not decrease the amount of Metropolitan water supply that would be available to the other member agencies in a WSAP. Programs that utilize Metropolitan supplies as a primary or in-lieu source or as a means of payback or future replenishment may have the effect of decreasing supplies, available to other agencies, if designated as Extraordinary Supply.

Provides Supply in Addition to Existing Regional Supplies

A potential Extraordinary Supply should provide a water supply that increases the overall water supplies that are available to the region in a WSAP. A program that is designed to move existing regional supplies from year to year would not qualify.

Specifically Designed Program or Supply Action

A potential Extraordinary Supply must be intentionally created and operated to provide additional supply yield. Normal variations in existing and planned local supply programs would not qualify.

Intended for Consumptive Use in a WSAP

A potential Extraordinary Supply should be designed with the primary intention to deliver water supply to a member agency only at a time when Metropolitan is allocating supplies. Programs designed to deliver water on a regular basis would not qualify. Exceptions for reasonable use of a supply program for emergency or other extenuating local circumstances should be considered.

Fully Documented Resource Management Actions

A potential Extraordinary Supply should have a full description as to the source, transmission, distribution, storage, and delivery of the water supply.

These principles are intended to identify deliberate actions taken by member agencies to augment supplies only when Metropolitan is allocating supplies through the WSAP. Production from existing local supplies, programs that are operated on an ongoing basis, and incidental increases in water supply would not qualify as Extraordinary Supply. The intent of the Extraordinary Supply designation is to recognize programs and actions that are additive to the total regional water supply as the region continues to confront the water supply challenges from drought and regulatory conditions. To that end, any supply actions taken after the initial implementation of the WSAP in July 2009 that utilize Metropolitan supplies either as a primary source, or to refill or replenish an incurred obligation or deficit at a future date would not qualify as Extraordinary Supply.

Appendix I: Base Period Mandatory Rationing Adjustment

Agencies that were under mandatory water use restrictions during the Base Period may have water use that is lower due to the mandatory actions already taken. Without adjusting for this, those agencies could be required to enforce even higher levels of restrictions under an allocation than those agencies that had not started mandatory restrictions.

To qualify for a Base Period Mandatory Rationing Adjustment, the member agency must provide Metropolitan staff with the following information:

- Time period when the mandatory conservation was in effect; it must be in effect during the Base Period
- A statement, with documentation, of how drought restrictions comply with the following Mandatory Conservation qualifications:
    - Governing Body-authorized or enacted
    - Includes mandatory demand reduction actions, restrictions or usage limitations including penalty-backed water budgets
    - Enforced by assessing penalties, fines, or rates based upon violating restrictions or exceeding usage limitations
- If the agency in question is a retail subagency, then the retailer's base period water demands during the Base Period in order to determine proportion to the member agency's total demand
- Historical data to construct GPCD base and trend for the consultation

Calculating the Base Period Rationing Adjustment involves following steps:

- Use the Baseline GPCD 10 or 15-year period selected by member agency for the Conservation Demand Hardening Adjustment calculation.
- Interpolate from the GPCD value of the midpoint of the Baseline GPCD period to the average GPCD of the two years preceding the agency's mandatory conservation
- Extrapolate to the WSAP Base Period (FY2013 and FY2014)
- Calculate the difference between estimated and observed GPCD for FY2013 and FY2014
- Convert to Acre-Feet and add to the member agency's Base Period Retail Demands

Appendix J: Per-Capita Water Use Minimum Example

This adjustment creates a minimum per capita water use threshold. Member agencies' retail-level water use under the WSAP is compared to two different thresholds. The minimum water use levels are based on compliance guidelines for total and residential water use established under Senate Bill X7-7.

Total Retail Level Use: 100 GPCD
Residential Retail Level Use: 55 GPCD

Agencies that fall below either threshold under the WSAP would receive additional allocation from Metropolitan to bring them up to the minimum GPCD water use level. To qualify for this credit, member agencies must provide documentation of the total agency level population and the percent of retail level demands that are residential; no appeal is necessary.

The following example gives a step-by-step description of how the Low Per-Capita Water Use Adjustment would be calculated for a hypothetical member agency. All numbers are hypothetical for the purpose of the example and do not reflect any specific member agency. This example was calculated using the following assumptions:

Allocation Year Retail Demand: 50,000 acre-feet
Allocation Year Local Supplies: 25,000 acre-feet;
Allocation Year Wholesale Demand: 25,000 acre-feet
Base Period Conservation: 5,000 acre-feet
Agency Population: 375,000
Percent of Retail Demands that are Residential: 60%

Step 1: Calculate Total Retail-Level Allocation Year Supplies

Table 6 shows the Allocation Year Local Supply, WSAP Allocation, and the total Allocation Year Supplies for the example agency at each Regional Shortage Level. The WSAP Allocation was calculated using the methodology detailed in Appendix G: Water Supply Allocation Formula Example and the assumptions listed above.

Table 6: Total Retail Level Allocation Year Supplies			
Regional Shortage Level	**Allocation Year Local Supply**	**WSAP Allocation**	**Total Allocation Year Supply**
1	25,000	23,594	48,594
2	25,000	22,188	47,188
3	25,000	20,781	45,781
4	25,000	19,375	44,375
5	25,000	17,969	42,969
6	25,000	16,563	41,563
7	25,000	15,156	40,156
8	25,000	13,750	38,750
9	25,000	12,344	37,344
10	25,000	10,938	35,938

Step 2: Calculate the Equivalent Total and Residential GPCD

The next step is to calculate the equivalent water use in gallons per capita per day (GPCD) for the Total Allocation Year Supply. The following equation shows the GPCD calculation under Regional Shortage Level 10.

$$35{,}938 \text{ af} * 325{,}851 \text{ gallons} \div 375{,}000 \text{ people} \div 365 \text{ days} = 85.6 \text{ GPCD}$$

The residential per-capita water use is calculated in the same manner. Based on the assumption that 60% of the agency demands are residential, the following equation shows the residential GPCD calculation under Regional Shortage Level 10.

$$35{,}938 \text{ af} * 60\% * 325{,}851 \text{ gallons} \div 375{,}000 \text{ people} \div 365 \text{ days} = 51.3 \text{ GPCD}$$

Step 3: Compare the Total and Residential GPCD to the Minimum Water Use Thresholds

The next step is to compare the total GPCD water use to the 100 GPCD total water use threshold. In a Regional Shortage Level 10, the WSAP results in an allocation that is 14.4 GPCD below the minimum threshold.

$$100 \text{ GPCD} - 85.6 \text{ GPCD} = 14.4 \text{ GPCD}$$

Likewise the residential GPCD water use is compared to the 55 GPCD residential water use threshold.

$$55 \text{ GPCD} - 51.3 \text{ GPCD} = 3.7 \text{ GPCD}$$

Step 4: Determine the Allocation Adjustment in Acre-Feet

The final step is to calculate the acre-foot equivalent of the GPCD that fell below the minimum threshold. In a Regional Shortage Level 10, the adjustment provides 6,068 acre-feet of additional allocation to the agency; the results for Shortage Levels 1-10 are shown in Table 7.

$$14.4 \text{ GPCD} \div 325{,}851 \text{ gallons} * 375{,}000 \text{ people} * 365 \text{ days} = 6{,}068 \text{ acre-feet}$$

Table 7: Total Per-Capita Water Use Adjustment				
Regional Shortage Level	**Allocation Year Supply**	**Equivalent GPCD**	**GPCD Below Threshold**	**Allocation Adjustment**
1	48,594	115.7	0	0
2	47,188	112.3	0	0
3	45,781	109.0	0	0
4	44,375	105.6	0	0
5	42,969	102.3	0	0
6	41,563	98.9	1.1	443
7	40,156	95.6	4.4	1,849
8	38,750	92.3	7.7	3,255
9	37,344	88.9	11.1	4,662
10	35,938	85.6	14.4	6,068

Again, this step is repeated for the residential water use. In a Regional Shortage Level 10, the adjustment provides 1,540 acre-feet of additional allocation to the agency; the residential water use results for Regional Shortage Levels 1-10 are shown in Table 8.

$$3.7 \text{ GPCD} \div 325{,}851 \text{ gallons} * 375{,}000 \text{ people} * 365 \text{ days} = 1{,}540 \text{ acre-feet}$$

Table 8: Residential Per-Capita Water Use Adjustment				
Regional Shortage Level	**Allocation Year Supply**	**Equivalent GPCD**	**GPCD Below Threshold**	**Allocation Adjustment**
1	29,156	69.4	0	0
2	28,313	67.4	0	0
3	27,469	65.4	0	0
4	26,625	63.4	0	0
5	25,781	61.4	0	0
6	24,938	59.4	0	0
7	24,094	57.4	0	0
8	23,250	55.4	0	0
9	22,406	53.3	1.7	697
10	21,563	51.3	3.7	1,540

Agencies that fall below either threshold under the WSAP would receive additional allocation from Metropolitan to bring them up to the minimum GPCD water use level. If an agency qualifies under both thresholds, the one resulting in the maximum allocation adjustment would be given. Under this example the agency would receive 6,068 acre-feet of additional allocation in a Regional Shortage Level 10.

Appendix K: Qualifying Income-Based Rate Allocation Surcharge Adjustment Example

The following example provides a step by step description of how the qualifying income-based rate allocation surcharge adjustment is calculated. To qualify for this adjustment, member agencies must provide documentation showing the amount of retail demands that are covered by a qualifying income-based rate; no appeal is necessary.

The following list summarizes the allocation year demands, local supplies, and allocation as calculated in Appendix G: Water Supply Allocation Formula Example for a hypothetical agency under a Level 4 Regional Shortage. For detailed instructions on how to calculate these figures, reference Appendix G: Water Supply Allocation Formula Example.

Allocation Year Retail Demand: 133,000 acre-feet
Allocation Year Local Supplies: 68,000 acre-feet;
Level 4 WSAP Allocation: 52,735 acre-feet

Step 1: Allocation Surcharge Calculation

(a) **Water Use above Allocation:** The first step in calculating the income-based rate Allocation Surcharge adjustment is to calculate the agency's total Allocation Surcharge under the WSAP. If the agency did not incur any Allocation Surcharge from the allocation year, the income-based rate allocation surcharge adjustment would not apply. For the purpose of this example, the agency used 61,000 acre-feet of MWD supplies in the allocation year. This represents 8,265 acre-feet of use above the water supply allocation.

WSAP Allocation	52,735 af
Actual MWD Water Use	61,000 af
Use Above WSAP Allocation	8,265 af

(b) **Total Allocation Surcharge:** In this example the agency used 115.7% of its water supply allocation. 7,910 of the 8,265 acre-feet of use above the allocation would be assessed the Allocation Surcharge at an amount of $1,480 per acre-foot and 354 of the 8,265 acre-feet of use above the allocation would be assessed the Allocation Surcharge at an amount of $2,960.

Between 100% and 115% of Allocation	7,910 af	$1,480/af	$11,706,800
Greater than 115% of Allocation	354 af	$2,960/af	$1,047,840
Total	8,265 af		$12,754,640

Step 2: Effective Income-Based Rate Cutback

(a) **Calculate Retail Cutback:** The second step in calculating the income-based rate allocation surcharge adjustment is to calculate the amount of supply cutback that would have been expected from qualifying income-based rate customers under the WSAP. Using the water supply allocation that was calculated above, the total retail level impact on the agency can be determined. In this example the agency receives a retail level cutback of 15,265 acre-feet, or 11.5% of their retail level demand.

WSAP Allocation + Allocation Year Local Supplies	117,735 af
Allocation Year Retail Demand	133,000 af
Effective Cutback	**15,265 af (11.5%)**

(b) Income-based Rate Customer Retail Cutback: To calculate the effective income-based rate cutback, the amount of demand covered by a qualifying income-based rate is multiplied by the effective retail level cutback. For this example assume that the agency has 10,000 acre-feet of qualifying demands.

Qualifying Income-Based Rate Demand	10,000 af
Effective Cutback Percentage	11.5%
Effective Income-Based Rate Cutback	**1,148 af**

(c) Income-based Rate Cutback Allocation Surcharge: Once the effective cutback has been calculated, the amount of Allocation Surcharge that is associated with qualifying income-based rate customers can be determined.

Between 100% and 115% of Allocation	794 af	$1,480/af	$1,175,120
Greater than 115% of Allocation	354 af	$2,960/af	$1,047,840
Total	**1,148 af**		**$2,222,960**

(d) Adjusted Allocation Surcharge Calculation: Finally, the Allocation Surcharge attributable to qualifying income-based rate customers is subtracted from the total Allocation Surcharge that was calculated above to determine the qualifying income-based rate adjusted allocation surcharge. In the case that the monetary amounts associated with the Income-Based Rate are greater than the total amounts an agency incurs, no Allocation Surcharge will be incurred.

Total Allocation Surcharge	$12,754,640
Qualifying Income-Based Rate Allocation Surcharge	$2,222,960
Qualifying Income-Based Rate Adjusted Allocation	**$10,531,680**

Appendix L: Groundwater Replenishment Allocation

Groundwater basins help provide vital local supplies that can buffer the region from short-term drought impacts. Longer droughts can result in reductions to the many sources of water that replenish groundwater basins, resulting in lower basin levels and potential impacts to the overlying consumptive demands. Limited imported deliveries under these conditions may help avoid impacts to the basins that may be drawn out of their normal operating range or subject to water quality or regulatory impacts. To this end, Metropolitan provides a limited allocation for drought impacted groundwater basins based on the following framework:

a) Staff hold a consultation with qualifying member agencies who have taken groundwater replenishment deliveries since 2010 and the appropriate groundwater basin managers to document whether their basins are in one of the following conditions:
    i. Groundwater basin overdraft conditions that will result in water levels being outside normal operating ranges during the WSAP allocation period; or
    ii. Violations of groundwater basin water quality and/or regulatory parameters that would occur without imported deliveries.
b) Provide an allocation based on the verified need for groundwater replenishment. The allocation would start with a member agency's ten-year average purchases of imported groundwater replenishment supplies (excluding years in which deliveries were curtailed). The amount would then be reduced by the declared WSAP Regional Shortage Level (5 percent for each Regional Shortage Level).
c) Any allocation provided under this provision for drought impacted groundwater basins is intended to help support and maintain groundwater production for consumptive use. As such, a member agency receiving an allocation under this provision will be expected to maintain groundwater production levels equivalent to the average pumping in the Base Period. Any adjustments to a member agency's M&I allocation due to lower groundwater production would be reduced by deliveries made under this provision.
d) Agencies for which this allocation does not provide sufficient supplies for the needs of the groundwater basin may use the WSAP Appeals Process to request additional supply (subject to Board approval). The appeal should include a Groundwater Management Plan that documents the need for additional supplies according to the following tenets:
    i. Maintenance of groundwater production levels;
    ii. Maintenance of, or reducing the further decline of, groundwater levels;
    iii. Maintenance of key water quality factors/indicators;
    iv. Avoidance of permanent impacts to groundwater infrastructure or geologic features; and
    v. Consideration of severe and/or inequitable financial impacts.

Final amounts and allocations will be determined following the consultations with groundwater basin managers and member agencies.

Appendix M: Water Rates, Charges, and Definitions

Table 9: Water Rates and Charges Dollars per acre-foot (except where noted)			
Rate	Effective 1/1/2014	Effective 1/1/2015	Effective 1/1/2016
Tier 1 Supply Rate	$148	$158	$156
Tier 2 Supply Rate	$290	$290	$290
System Access Rate	$243	$257	$259
Water Stewardship Rate	$41	$41	$41
System Power Rate	161	$126	$138
Tier 1	$593	$582	$594
Tier 2	$735	$714	$728
Treatment Surcharge	$297	$341	$348
Full Service Treated Volumetric Cost			
Tier 1	$890	$923	$942
Tier 2	$1,032	$1,055	$1,076
Readiness-to-Serve Charge (millions of dollars)	$166	$158	$153
Capacity Charge (dollars per cubic foot second)	$8,600	$11,100	$10,900

Definitions:

(1) **Tier 1 Supply Rate -** recovers the cost of maintaining a reliable amount of supply.

(2) **Tier 2 Supply Rate** - set at Metropolitan's cost of developing additional supply to encourage efficient use of local resources.

(3) **System Access Rate** – recovers a portion of the costs associated with the delivery of supplies.

(4) **System Power Rate** – recovers Metropolitan's power costs for pumping supplies to Southern California.

(5) **Water Stewardship Rate** – recovers the cost of Metropolitan's financial commitment to conservation, water recycling, groundwater clean-up and other local resource management programs.

(6) **Treatment Surcharge** – recovers the costs of treating imported water.

(7) **Readiness-to-Serve Charge -** a fixed charge that recovers the cost of the portion of system capacity that is on standby to provide emergency service and operational flexibility.

(8) **Capacity Charge** – the capacity charge recovers the cost of providing peak capacity within the distribution system.

Appendix N: Allocation Appeals Process

Step 1: Appeals Submittal

All appeals shall be submitted to the Appeals Liaison in the form of a written letter signed by the member agency General Manager. Each appeal must be submitted as a separate request, submittals with more than one appeal will not be considered. The appeal request is to include:

- A designated member agency staff person to serve as point of contact.
- The type of appeal (erroneous baseline data, loss of local supply, etc.).
- The quantity (in acre-feet) of the appeal.
- A justification for the appeal which includes supporting documentation.

A minimum of 60 days are required to coordinate the appeals process with Metropolitan's Board process.

Step 2: Notification of Response and Start of Appeals Process

The Appeals Liaison will phone the designated member agency staff contact within 3 business days of receiving the appeal to provide an initial receipt notification, and schedule an appeals conference. Subsequent to the phone call, the Liaison will send an e-mail to the Agency General Manager and designated staff contact documenting the conversation. An official notification letter confirming both receipt of the appeal submittal, and the date of the appeals conference, will be mailed within 2 business days following the phone contact

Step 3: Appeals Conference

All practical efforts will be made to hold an appeals conference between Metropolitan staff and member agency staff at Metropolitan's Union Station Headquarters within 15 business days of receiving the appeal submittal. The appeals conference will serve as a forum to review the submittal materials and ensure that there is consensus understanding as to the spirit of the appeal. Metropolitan staff will provide an initial determination of the size of the appeal (small or large) and review the corresponding steps and timeline for completing the appeals process.

Steps 4-7 of the appeals process differ depending upon the size of the appeal

Small Appeals

Small appeals are defined as those that would change an agency's allocation by less than 10 percent, or are less than 5,000 acre-feet in quantity. Small appeals are evaluated and approved or denied by Metropolitan staff.

Step 4: Preliminary Decision

Metropolitan staff will provide a preliminary notice of decision to the member agency within 10 business days of the appeals conference. The preliminary decision timeline may be extended to accommodate requests for additional information, data, and documentation. The Appeals Liaison will mail a written letter to the member agency staff contact and General Manager, stating the preliminary decision and the rationale for approving or denying the appeal.

Step 5: Clarification Conference

Following the preliminary decision the Appeals Liaison will schedule a clarification conference. The member agency may choose to decline the clarification conference if they are satisfied with the preliminary decision. Declining the clarification conference serves as acceptance of the preliminary decision, and the decision becomes final upon approval by Metropolitan's executive staff.

Step 6: Final Decision

Metropolitan staff will provide a final notice of decision to the member agency within 10 business days of the clarification conference, pending review by Metropolitan's executive staff. The Appeals Liaison will mail a written letter to the member agency staff contact and General Manager, stating the final decision and the rationale for the decision. A copy of the letter will also be provided to Metropolitan executive staff.

Step 6a: Board Resolution of Small Appeal Claims

Member agencies may request to forward appeals that are denied by Metropolitan staff to the Board of Directors through the Water Planning and Stewardship Committee for final resolution. The request for Board resolution shall be submitted to the Appeals Liaison in the form of a written letter signed by the member agency General Manager. This request will be administered according to Steps 6 and 7 of the large appeals process.

Step 7: Board Notification

Metropolitan staff will provide a report to the Board of Directors, through the Water Planning and Stewardship Committee, on all submitted appeals including the basis for determination of the outcome of the appeal.

Large Appeals

Large appeals are defined as those that would change an agency's allocation by more than 10 percent, and are larger than 5,000 acre-feet. Large appeals are evaluated and approved or denied by the Board of Directors.

Step 4: Preliminary Recommendation

Metropolitan staff will provide a preliminary notice of recommendation to the member agency within 10 business days of the appeals conference. The preliminary decision timeline may be extended to accommodate requests for additional information, data, and documentation. The Appeals Liaison will mail a written letter to the member agency staff contact and General Manager, stating the preliminary recommendation and the rationale for the recommendation. A copy of the draft recommendation will also be provided to Metropolitan executive staff.

Step 5: Clarification Conference

Following the preliminary recommendation the Appeals Liaison will schedule a clarification conference. The member agency may choose to decline the clarification conference if the satisfied with preliminary recommendation. Declining the clarification conference signifies acceptance of the preliminary recommendation, and the recommendation becomes final upon approval by Metropolitan's executive staff.

Step 6: Final recommendation

Metropolitan staff will provide a final notice of recommendation to the member agency within 10 business days of the clarification conference, pending review by Metropolitan executive staff. The Appeals Liaison will mail a written letter to the member agency staff contact and General Manager, stating the final recommendation and the rationale for the recommendation. A copy of the final recommendation will also be provided for Metropolitan executive review.

Step 7: Board Action

Metropolitan staff shall refer the appeal to the Board of Directors through the Water Planning and Stewardship Committee for approval.

Appendix O: Appeals Submittal Checklist

Appeal Submittal

- ☐ Written letter (E-mail or other electronic formats will not be accepted)
- ☐ Signed by the Agency General Manager

Mailed to the appointed Metropolitan Appeals Liaison

Contact Information

- ☐ Designated staff contact
    - o Name
    - o Address
    - o Phone Number
    - o E-mail Address
- ☐ General Manager
    - o Name
    - o Address
    - o Phone Number
    - o E-mail Address

Type of Appeal

- ☐ State the type of appeal
    - o Erroneous historical data used in base period calculations
        - Metropolitan Deliveries
        - Local Production
        - Growth adjustment
        - Conservation savings
    - o Exclusion of physically isolated areas
    - o Extraordinary supply designation
    - o Groundwater Replenishment Allocation
    - o Base Period Mandatory Rationing Adjustment
    - o Other

Quantity of Appeal

- ☐ State the quantity in acre-feet of the appeal

Justification and Supporting Documentation

- ☐ State the rationale for the appeal
- ☐ Provide verifiable documentation to support the stated rationale
    - o Examples of verifiable documentation Include, but are not limited to:
        - Billing Statements
        - Invoices for conservation device installations
        - Basin Groundwater/Watermaster Reports
        - California Department of Finance economic or population data
        - California Department of Public Health reports

Attachment C

Resolution Adopting the Water Shortage Contingency Plan

Resolution 9281

**RESOLUTION
OF THE BOARD OF DIRECTORS
OF THE METROPOLITAN WATER DISTRICT OF SOUTHERN CALIFORNIA
ADOPTING THE WATER SHORTAGE CONTINGENCY PLAN**

WHEREAS, the Urban Water Management Planning Act requires urban water suppliers providing water for municipal purposes to more than 3,000 customers or supplying more than 3,000 acre-feet of water annually to prepare and adopt, in accordance with prescribed requirements, a water shortage contingency plan;

WHEREAS, the Urban Water Management Planning Act specifies the requirements and procedures for adopting such Water Shortage Contingency Plans;

WHEREAS, the Urban Water Management Planning Act requires urban water suppliers to conduct an annual water supply and demand assessment (Annual Assessment) each year and to include in their water shortage contingency plans the procedures they use to conduct the Annual Assessment;

WHEREAS, the procedures used to conduct an Annual Assessment include, but are not limited to, the written decision-making process that an urban water supplier will use each year to determine its water supply reliability;

WHEREAS, The Metropolitan Water District of Southern California's (Metropolitan's) water shortage contingency plan provides that by June of each year, Metropolitan staff will present a completed Annual Assessment for approval by Metropolitan's Board of Directors or by the Board's authorized designee with expressly delegated authority for approval of Annual Assessment determinations;

and

WHEREAS, the Board of Directors of The Metropolitan Water District of Southern California has duly reviewed, discussed, and considered such Water Shortage Contingency Plan and has determined the Water Shortage Contingency Plan to be consistent with the Urban Water Management Planning Act and to be an accurate representation of the planned actions during shortage conditions for The Metropolitan Water District of Southern California.

NOW, THEREFORE, BE IT RESOLVED by the Board of Directors of The Metropolitan Water District of Southern California that, on May 11, 2021, this District hereby adopts this Water Shortage Contingency Plan for submittal to the State of California and expressly authorizes the General Manager of The Metropolitan Water District of Southern California to approve the Annual Assessment each year.

I HEREBY CERTIFY that the foregoing is a full, true and correct copy of a resolution adopted by the Board of Directors of The Metropolitan Water District of Southern California, at its meeting held on May 11, 2021.

Judy Abdo

Secretary of the Board of Directors
of The Metropolitan Water District
of Southern California

Appendix 6

CONSERVATION ESTIMATES AND WATER SAVINGS FROM CODES, STANDARDS, AND ORDINANCES

Appendix 6
CONSERVATION ESTIMATES AND WATER SAVINGS FROM CODES, STANDARDS, AND ORDINANCES

Background

Unlike traditional water supplies, which can be directly measured, conservation reduces water demand in ways that may only be indirectly quantified. Demand is reduced through changes in consumer behavior and savings from water-efficient fixtures. There are numerous approaches for estimating and projecting conservation savings, and many of them are utility-specific to meet the unique needs of different water agencies. Metropolitan estimates savings from the extensive existing conservation programs that it funds directly, as well as savings produced by plumbing codes. Metropolitan also incorporates the savings due to the impacts of price on consumers in its demand forecasts. These conservation savings estimates are incorporated into Metropolitan's long-term planning documents such as the Integrated Water Resources Plan (IRP) and its Urban Water Management Plan (UWMP).

Conservation savings are commonly estimated from a base-year water-use profile. Beginning with the 1996 IRP, Metropolitan identified 1980 as the base year for estimating conservation because it marked the effective date of a new plumbing code in California. Among other changes, the new code required toilets in new construction to be rated at 3.5 gallons per flush or less. Between 1980 and 1990, Metropolitan's service area saved an estimated 250 TAF per year as the result of this 1980 plumbing code and unrelated water rate increases. Within Metropolitan's planning framework, these savings are referred to as "pre-1990 savings." Metropolitan's conservation accounting combines pre-1990 savings and estimates of more recently achieved savings from the following sources of conservation:

- Active Conservation – Water saved directly as a result of conservation programs by water agencies. Active conservation is unlikely to occur without agency action.
- Code-Based Conservation – Water saved as a result of changes in water efficiency requirements for plumbing fixtures in plumbing codes. Sometimes referred to as "passive conservation," this form of conservation would occur as a matter of course without any additional action from water agencies.
- Price-Effect Conservation – Water saved by retail customers attributable to the effect of changes in the real (inflation-adjusted) price of water. Because water has a positive price elasticity of demand, increases in water price will decrease the quantity of water demanded.

Metropolitan's Conservation Estimate

In September 19, 2014, Governor Brown signed SB 1420 (Wolk, D-Davis), which added Section 10631(e)(4) to the Water Code. This Section provided that "water use projections may display and account for the water savings estimated to result from adopted codes, standards, ordinances, or transportation and land use plans" if that information is available and applicable to an urban water supplier. SB 606 (Hertzberg) amended Water Code Section 10631(e)(4), which is now Section 10631(d)(4) and applies only to retailers. This Section now requires that water use projections, where available, must "display and account for the water savings estimated to result from adopted codes, standards, ordinances, or transportation and land use plans identified by the urban water supplier, as applicable to the service area."

Metropolitan's conservation estimate is a comprehensive representation of Metropolitan's active conservation activities. It includes a combination of: (1) fixture/program-related savings, and (2) an estimate of code-based plumbing code conservation savings from a 1990 base year. In addition, price-effect savings are calculated using Metropolitan's MWD-EDM, a statistical model used to forecast retail water demands. Potential savings from public outreach and education programs are not included in Metropolitan's conservation estimate.

Distinguishing between active, code-based, and price-effect conservation can be complex when, for example, active programs for fixtures are implemented concurrently with conservation-related plumbing codes. Metropolitan's conservation estimate combines active, code-based, and price-effect conservation savings using methods that avoid double counting. Currently, 96 devices and programs are accounted for in estimating active conservation. These devices are spread across residential, landscape, commercial, industrial, and institutional sectors. There are eight fixtures tied to Code-based conservation estimate.

Metropolitan's conservation estimate is developed in cooperation with its 26 member agencies and falls into three general categories:

- Single-family residential (SFR),
- Multi-family residential (MFR), and
- Commercial, industrial, and institutional (CII).

Active Conservation

Estimated savings for active conservation account for programs administered by Metropolitan and its member agencies since 1990. These savings are calculated by combining counts of active program activity – numbers of devices and/or program implementations – with device-related water savings factors. These factors include:

- Savings per device/implementation
- Device life expressed in years
- Decay rate expressed as percent decay per year

Device savings estimates reflect the key assumptions outlined above. Devices may be represented more than once due to different implementation methods or savings factors. Assumptions are periodically reviewed to ensure they represent the best available savings estimates. Device-specific savings are adjusted to account for performance decay rates, or device life, but not both. For example, a residential premium high-efficiency toilet (PHET) saves about 9.4 gallons per day when replacing a 1.6 gallons per flush toilet. Lifetime savings would assume a physical life of 20 years and no performance decay.

Code-Based Conservation

Code-Based conservation accounts for water saved as a result of changes in water efficiency requirements for plumbing fixtures in plumbing codes. Plumbing code conservation is the impact of plumbing codes and other ordinances on water demand. Metropolitan's Code-Based conservation estimate represents plumbing code conservation with demographically-driven stock models. The stock models are device- or fixture- specific and are based on the same demographic data used in Metropolitan's retail demand projection. Each stock model considers the stocks and flows of conserving and non-conserving water devices, providing estimates of the impacts of plumbing codes on device saturation and overall savings.

Metropolitan's Code-based conservation estimate accounts for the following:

- New Construction: Water fixtures installed due to new construction are assumed to be in compliance with the plumbing codes in effect when the new construction occurs. For instance, a house built in 1997 would meet the efficiency standards set by California's 1992 plumbing code. Therefore, new construction is assumed to result in measurable savings from 1990, which is the baseline for conservation savings calculations. Estimates and projections of the number of fixtures added through new housing units and offices are based on growth in housing units or employment.
- Natural Replacement: Natural replacement accounts for the savings that accrue when fixtures are replaced with more efficient models due to remodeling, failure, or for other reasons. Metropolitan's savings estimate represents this effect with a "natural replacement rate" that is expressed as a percentage of existing fixtures that are replaced in a given year. Natural replacement rates vary by device and are linked to the expected life of the device. Devices with short lifespans will be replaced more frequently and thus have higher natural replacement rates. A simple percentage is used to account for this natural turn-over in non-conserving fixtures because it is difficult to back-calculate the age of the fixtures in pre-1990 construction.
- Fixtures Up for Renewal: As water-conserving fixtures reach their useful lives and become defective or inefficient, they may be replaced with water conserving fixtures due to plumbing codes. The water savings from the device is then considered "renewed" savings, which is tracked in Metropolitan's savings estimate. For example, a fixture that was installed through an active conservation program provides water savings that otherwise would not have been realized without plumbing codes. However, subsequent adoption of efficient plumbing codes means that when the fixture reaches the end of its life, it will be replaced by the same or more water-efficient model.

Stock Models

The number of efficient fixtures for each stock model is the sum of fixtures from active programs, new construction, natural replacement, and fixtures up for renewal. Table A.6-1 below shows the fixtures and devices that are assigned stock models based on existing plumbing codes.

Table A.6-1
Stock Models

Residential	CII
Toilets	Toilets
Showerheads	Urinals
Faucet Aerators	Pre-Rinse Spray Heads
Washing Machines	Washing Machines

The Stock Models generate separate annual estimates of devices and fixtures for tracking active conservation savings, while also accounting for the impacts of active programs on the overall device saturation rate. As a result, increased levels of active conservation lead to lower levels of plumbing code conservation. This helps avoid double counting in Metropolitan's conservation savings estimate.

Plumbing Code Assumptions

Plumbing code savings are determined by the device-specific assumptions used in the stock models, presented in Table A.6-2. The stock models are driven by projections of housing and employment consistent with the demand projections. Initial device counts and growth in the number of devices are determined by the combination of demographic information and the following assumptions:

- Devices per Household or Per Employee: This factor represents the average number of devices per household or per employee and is multiplied by the demographic projections to develop estimates of total number of devices or "stock." Devices per household and employee can vary by agency and change over time.
- Plumbing Code Compliance Rate: The plumbing code compliance rate is expressed as a percent and serves two purposes: (1) it indicates the presence of a plumbing code in a specific year, and (2) it determines the overall compliance rate with the plumbing code. This allows plumbing code effects to be phased in over several years.
- Natural Replacement Rate: This represents the rate at which existing non-conserving devices are converted to conserving devices due to remodeling or device failure. It has a strong impact on the saturation rate of devices that existed prior to plumbing codes, such as pre-1992 toilets.
- Device Life: The stock models also account for device life for water-efficient devices installed after 1990. This allows the stock model to track devices installed through active conservation as they reach the end of their life and are replaced due to plumbing codes. The stock models use the same device life specified in the savings assumptions.

Table A.6-2
Plumbing Code Assumptions

Stock Model	Device per Household/ Employee	Compliance Rate	Natural Replacement Rate	Plumbing Code Year
Res. Toilets	2	99%	2%	1994/2014
Res. Shower Heads	1.8	95%	10%	1994
Res. Aerators	3.5	90%	33%	1994
Res. Washing Machine	0.74	100%	6.7%	2018
CII Toilets	0.27*	100%	2%	1994/2014
CII Urinals	0.06	100%	4%	1994
CII Pre-Rinse Spray Heads	0.0055*	95%	16.7%	2006
CII Washing Machine	0.0073*	100%	5%	2007

* Varies over time and by agency (based on CUWCC BMPs savings factors)

These assumptions are derived from California Urban Water Conservation Council (CUWCC) conservation reports, American Water Works Association Research Foundation's 1999 end use study, Metropolitan's Orange County Saturation Study, and other sources. In the residential sector, devices per household combine single family and multifamily trends.

Model Water Efficient Landscape Ordinance

The California Water Commission adopted an updated Model Water Efficient Landscape Ordinance (MWELO) on July 15, 2015. The MWELO promotes efficient landscapes in new developments and retrofitted landscapes. The MWELO increases water efficiency standards for new and retrofitted landscapes through more efficient irrigation systems, greywater usage, onsite storm water capture, and by limiting the portion of landscapes that can be covered in turf. Local agencies had until December 1, 2015 to adopt the MWELO or to adopt a Local Ordinance which must be at least as effective in conserving water as MWELO. Local agencies working together to develop a Regional Ordinance had until February 1, 2016 to adopt, but they are still subject to the December 2015 reporting requirements. Local agencies were required to report on the implementation and enforcement of local ordinances by December 31, 2015.

Metropolitan's modeling of Code-based conservation includes a calculation of savings that would result from 50 percent of new households having efficient outdoor water use consistent with MWELO. The 50 percent compliance rate for new households is a conservative estimate based on an assessment of the efficacy of the current MWELO ordinance.

Price Savings Assumptions

Price-effect savings are calculated by comparing MWD-EDM demand projections with price increases to demand projections with constant 1990 water rates. The difference is the price-effect savings measured from a 1990 base. Price-effect savings increase as prices rise over time; they also increase as the household and employment base grow. A price increase applied to 1,000 households will generate more water savings than the same price increase applied to 500 households.

Un-metered Water Use Savings

A final category of savings tracked by Metropolitan is a product of other conservation efforts. MWD-EDM projects un-metered water use as a fixed percentage of total retail M&I demand. As conservation savings lowers residential and CII demands, it lowers un-metered use by the same percent. For instance, if conservation reduces M&I demands by 10 percent in 2020 (compared to demands before conservation), un-metered water use is also reduced 10 percent. This reduction is based on the assumption that un-metered use varies according to overall demand and that reducing overall use also reduces un-metered use. The reduction in un-metered water use is captured in the MWD-EDM model and included as a conservation source.

The total conservation savings are shown in Table A.6-3.

Table A. 6-3 Conservation Savings (acre-feet)

	1990	1995	2000	2005	2010	2015	2020	2025	2030	2035	2040	2045	2050
Active Savings	0	26,000	59,000	94,000	133,000	152,000	144,000	93,000	55,000	35,000	25,000	17,000	0
Code-Based Savings	0	83,000	177,000	244,000	291,000	370,000	472,000	560,000	623,000	665,000	701,000	731,000	757,000
Price Savings	0	31,000	62,000	94,000	125,000	156,000	187,000	205,000	229,000	258,000	293,000	333,000	379,000
Un-metered Water Savings	0	9,000	18,000	26,000	35,000	44,000	52,000	53,000	54,000	55,000	56,000	57,000	58,000
Pre-1990 Savings	250,000	250,000	250,000	250,000	250,000	250,000	250,000	250,000	250,000	250,000	250,000	250,000	250,000
Total	**250,000**	**399,000**	**566,000**	**708,000**	**834,000**	**972,000**	**1,105,000**	**1,161,000**	**1,211,000**	**1,263,000**	**1,325,000**	**1,388,000**	**1,444,000**

Note: Metropolitan's conservation savings projection includes savings from Metropolitan's Conservation Credits Program, code-based conservation, price effect conservation, and pre-1990 device retrofits. The projection does not include savings from the implementation of future active conservation programs.

Appendix 7

DISTRIBUTION SYSTEM WATER LOSSES

Appendix 7
DISTRIBUTION SYSTEM WATER LOSSES

California Water Code Section 10631(d)(3) requires urban retail suppliers to quantify distribution system water loss for each of the five years preceding the plan update, based on water system balance methodology developed by the American Water Works Association (AWWA). For the 2020 UWMP, Metropolitan is voluntarily reporting its distribution system water loss. Metropolitan followed the AWWA Water Audit methodology to track all sources of treated water and uses of treated water within its system. The AWWA Water Audit methodology quantifies real and apparent water system losses in an agency's distribution system.

For its voluntary reporting of distribution system water losses, Metropolitan included its water balance audit for calendar years 2015 through 2019. The results of Metropolitan's audit showed that the average water losses for its treated distribution system over the last five years from 2015 to 2019 is approximately 7.8 TAF. The water loss estimates are presented in Tables A.7-1 through A.7-5.

In addition to the distribution system losses described in the AWWA tables, Metropolitan estimates that 41.6 TAF was lost from reservoir evaporation occurring in Lake Mathews, Lake Skinner, and Diamond Valley Lake during calendar year 2019.

Appendix 8

METROPOLITAN's EMERGENCY STORAGE OBJECTIVE

Appendix 8
METROPOLITAN'S EMERGENCY STORAGE OBJECTIVE

Metropolitan established its original criteria for determining emergency storage requirements in the October 1991 Final Environmental Impact Report for the Eastside Reservoir, which is now named Diamond Valley Lake. Emergency storage requirements are based on the potential of a major earthquake that would damage all supply aqueducts isolating Southern California from its imported water sources. The emergency storage criteria developed within the Eastside Reservoir EIR were again discussed in the 1996 Integrated Water Resources Plan. Metropolitan's Board approved both of these documents.

In 2019, Metropolitan and its member agencies completed a process to update the emergency criteria and methodology for determining the regional planning estimate of emergency storage under Metropolitan's Emergency Storage Objective. This planning estimate of emergency storage represents the amount of water that Metropolitan would store for the region to prepare for a catastrophic earthquake that would damage the aqueducts that transport imported water supplies to Southern California, including: the Colorado River Aqueduct, both the East and West branches of the California Aqueduct, and the Los Angeles Aqueduct. These emergency supplies, stored in Metropolitan and DWR existing surface reservoirs within the region, will allow Metropolitan to deliver reserve supplies to the member agencies to supplement their local production during a catastrophic earthquake or other disaster. This helps avoid severe water shortages during periods when the imported water aqueducts may be out of service.

The Emergency Storage Objective considers a six- and twelve-month outage period for the imported supply aqueducts, based on latest seismic information and estimates of repair duration for the different aqueducts. It also accounts for the operational flexibility of Metropolitan's distribution system, a retail water demand cutback ranging from 25 to 35 percent considering the level of conservation that the region achieved during the recent drought, and an aggregated loss of 10 to 20 percent of local supplies accounting for factors that could affect local production during emergency conditions.

Under this update, Metropolitan's Emergency Storage Objective was set to 750,000 acre-feet, as this level of storage would prevent severe water shortages to the region given new information on expected recovery durations. While the emergency storage would allow Metropolitan to deliver reserve supplies to the member agencies to meet their water needs during a catastrophic event, it is not intended to set a basis or a policy for allocating or apportioning storage for any individual member agency.

Included in this appendix is a copy of the Board Information Letter to Metropolitan's Water Planning and Stewardship Committee dated May 14, 2019. This Board Information Letter and the attached draft white paper review the history, policy, and criteria for evaluating a regional planning estimate for emergency storage and describe the more than year-long coordination process between Metropolitan and its member agencies in developing the region's estimate for Emergency Storage Objective.

5/14/2019 Board Meeting

9-3

Subject

Update of Metropolitan's Emergency Storage Objective

Executive Summary

In February 2018, The Metropolitan Water District of Southern California (Metropolitan) and its member agencies embarked on a process to evaluate regional storage including how the storage programs performed during this post decade of drought and revisiting the size and management of Metropolitan's emergency storage reserve. This process aims to maximize the potential for optimizing performance and operations of Metropolitan's storage programs. As part of the process, a Workgroup comprised of Metropolitan staff and representatives from member agencies evaluated Metropolitan's emergency storage objective.

Metropolitan, in coordination with the Workgroup, completed the attached draft White Paper on emergency storage, which summarizes the progress to date in estimating a planning objective for the region's emergency storage.

Details

The White Paper reviews the history, policy, and criteria for evaluating a regional planning estimate for emergency storage. This evaluation prepares for major earthquake or other damage to the aqueducts that import water to Southern California. The emergency storage would allow Metropolitan to deliver reserve supplies to the member agencies to supplement local production. This would help avoid severe water shortages while one or more of the imported water aqueducts may be out of service.

The White Paper also describes the mechanisms the Workgroup employed, including: (1) updated emergency criteria, and (2) a revised methodology to evaluate emergency storage.

Updating emergency criteria involved revising the outage durations based on the latest seismic information, and revisiting retail water demands and locally available supplies within the service area. It also accounted for the member agencies' unique situations in identifying practicable ranges of reduction of retail water demands through conservation and production levels of local water supplies during an imported supply emergency outage.

The proposed emergency storage volume considers various combinations of criteria to determine an envelope of acceptable scenarios designed to prevent severe shortages during the outage. Under this approach, the Workgroup focused on a range of values from 520,000 to 830,000 acre-feet (AF). With input from the Workgroup, staff recommends increasing the emergency storage objective to 750,000 AF. This recommended volume would be distributed amongst the available capacities of in-region Department of Water Resources and Metropolitan surface reservoirs.

The recommended emergency storage volume of 750,000 AF is an increase from the current planning target of 630,000 AF. A longer outage period based on damage restoration analysis and a consideration of lower local supply production attributed to this recommended increase in emergency storage.

The emergency storage volume presented in the White Paper represents a planning estimate for the amount of water that Metropolitan would store for the region in preparation for a catastrophic earthquake or other disaster. It is not intended to set a basis or a policy for allocating or apportioning storage for any individual member agency. Staff will review and incorporate additional Board and Workgroup feedback in finalizing the White Paper. Staff will transmit the final White Paper to the Board and the member agencies.

Staff proposes to revisit the emergency storage periodically, and incorporate the analysis into the Integrated Water Resources Plan update process. In addition, a detailed review of the spatial distribution of storage and operation of the distribution system will be part of Metropolitan's continued efforts to evaluate the storage portfolio. This next phase of evaluating Metropolitan's regional storage portfolio is expected to be completed by spring of 2020.

Policy

By Minute Item 50358, dated January 12, 2016, the Board adopted the 2015 Integrated Water Resources Plan Update, as set forth in Agenda Item 8-3 board letter.

By Minute Item 50473, dated May 10, 2016, the Board adopted the 2015 Urban Water Management Plan, as set forth in Agenda Item 8-6 board letter.

Fiscal Impact

2018 Evaluation of Regional Storage Portfolio
DRAFT Evaluation of Metropolitan's Emergency Storage Objective

SUMMARY

In February 2018, the Metropolitan Water District of Southern California (Metropolitan) and its member agencies embarked on a process for the Evaluation of Regional Storage Portfolio (ERSP) to maximize potential for performance and operations of Metropolitan's storage programs. As part of the ERSP process, a Workgroup comprised of Metropolitan staff and representatives from member agencies evaluated Metropolitan's Emergency Storage Objective (Emergency Storage).

This White Paper provides a summary of the history, policy, and criteria for evaluating a regional planning estimate for the Emergency Storage. This evaluation assumes major earthquake damage to the aqueducts that transport imported water supplies to Southern California. The Emergency Storage allows Metropolitan to deliver reserve supplies to the member agencies to supplement local production. This helps avoid severe water shortages during periods when the imported water aqueducts may be out of service.

This White Paper describes: (1) updating the emergency criteria, and (2) revising the methodology for calculating the Emergency Storage.

In the review and update of emergency criteria, the Workgroup considered the 2015 Integrated Water Resources Plan (IRP) and centered on the following:

- A retail water demand cutback of 25 to 35 percent appears reasonable, based on the level of conservation that the region achieved during the recent drought; and
- A six-and 12-month aggregated loss of 10 to 20 percent of local production reported in the IRP seems reasonable. This allows a contingency for some damage to local facilities and accommodates variable durations of local repairs.

The Workgroup discussion also led to a new concept of an "envelope of solutions" to estimate an appropriate Emergency Storage for the region. The envelope concept shifts from a single equation and volume for determining emergency storage. Instead, it considers various combinations of criteria to determine a range of acceptable scenarios for Emergency Storage. The prior methodology assumed a single region-wide scenario of conservation and local production loss. This envelope concept underscores member agencies' unique situations while taking into account their inputs in identifying practicable ranges of decreases in retail water demands and local production. The Workgroup focused on an acceptable range of Emergency Storage values from 520,000 to 830,000 acre-feet (AF).

Based on input from the process, staff recommends the following:

- The Emergency Storage Objective should increase from 630,000 AF to 750,000 AF. This level of storage would prevent severe water shortages to the region given new information on expected recovery durations.
- Metropolitan should revisit the Emergency Storage Objective periodically, possibly following the completion of any new IRP with the latest information on damage scenarios, local supplies, imported water demand, and attainable conservation.

DETAILED REPORT

Background

Metropolitan's need for Emergency Storage is based on the potential for major earthquake damage to the Colorado River Aqueduct, California Aqueduct, and Los Angeles Aqueduct. Metropolitan coordinates with the member agencies in setting the emergency criteria, which forms the basis for establishing the Emergency Storage. These criteria assume that damage from such a catastrophic event could render the aqueducts that transport imported water supplies to Southern California out of service, isolating the region from its imported water supplies. Metropolitan's objective is to provide regional emergency storage that could allow Metropolitan to deliver supplies to all its member agencies during this period of outage. The Emergency Storage allows Metropolitan to continue deliveries to its member agencies to supplement local water production and release from local storage. This helps avoid severe water shortages during periods when aqueducts are out of service. In addition to Emergency Storage, Metropolitan may draw from dry-year storage during an emergency, if necessary and available.

Metropolitan's emergency planning criteria were previously established and reported in the following documents:

1. Final Environmental Impact Report for the Eastside Reservoir (now named the Diamond Valley Lake) dated October 1991, which was adopted by the Board on September 24, 1991;
2. Southern California's 1996 Integrated Water Resources Plan, which was adopted by the Board on January 9, 1996;
3. Reports on Metropolitan Water Supplies dated February 2002 and March 2003;
4. 2006 IRP Implementation Report, which was presented to the Board on September 11, 2006 and transmitted on October 9, 2006;
5. Metropolitan's Emergency Storage Requirement, a written report presented to the Board on May 11, 2010; and
6. The 2015 Urban Water Management Plan dated June 2016, which was adopted by the Board on May 10, 2016.

Metropolitan's Current Emergency Criteria

Metropolitan's current emergency criteria provide for a six-month water supply at 75 percent of member agencies' retail demand under normal hydrologic conditions. Metropolitan's emergency plan outlines that under catastrophic loss of water supply the following actions will be implemented, which serve as the criteria for determining Metropolitan's Emergency Storage:

1. any existing interruptible water deliveries would be suspended;
2. firm supplies to member agencies would be restricted by a mandatory cutback of 25 percent from normal year retail demand levels;
3. water stored in the surface reservoirs and groundwater basins under Metropolitan's interruptible program would be made available;
4. full local groundwater production, recycled water, and local surface emergency storage reserve production would be sustained; and
5. Metropolitan would draw on its emergency storage as well as other available storage.

These emergency planning criteria were the basis for the current Metropolitan's Emergency Storage planning level of 630, 000 AF.

Review and Update of Metropolitan's Emergency Criteria

The following sections detail the updated assumptions and changed conditions since the last evaluation of Emergency Storage in 2010. These include demand and supply forecasts developed for the 2015 IRP, updated studies on the potential for seismic damage and outage periods for the imported supply aqueducts, and flexibility improvements within Metropolitan's distribution system implemented as a result of recent drought and supply challenges. This new information is critical to the review and update of the emergency criteria, which forms the basis for revising the Emergency Storage.

Outage Period Criteria

The outage period pertains to the amount of time the regional aqueducts that deliver imported water to Southern California may be out of service. This outage period is derived from the estimated restoration timelines based on the nature of potential damage to the aqueduct coupled with the operational ability to deliver supplies to the area served by that specific aqueduct. During an emergency outage period, Metropolitan's member agencies will depend on previously stored imported and local supplies to supplement continued local production in meeting reduced levels of retail demands. It is acknowledged that some areas could be more impacted because they are primarily or exclusively fed by an imported aqueduct which is assumed to sustain damage. However, Metropolitan's objective is to continue building and operating its system with flexibility to respond to various potential damage scenarios.

Recent Seismic Studies

In August 2015, Metropolitan, Los Angeles Department of Water and Power (LADWP), and California Department of Water Resources (DWR) formed the Seismic Resilience Water Supply Task Force (Task Force) for the purpose of collaborating on studies and mitigation measures to improve the reliability of imported water supplies to Southern California. The specific goals of the Task Force included:

- Revisiting historical assumptions regarding potential aqueduct outages;
- Establishing a common understanding about individual agency aqueduct vulnerability assessments, projected damage scenarios, and planning assumptions; and
- Discussing ideas for improving the resilience of Southern California's imported water supplies through multi-agency cooperation.

Through exchange of information and ideas between the three agencies and experts from the industry and academia, the Task Force assessed potential aqueduct damage and restoration timeline for a M 7.8 earthquake on the San Andreas Fault. This scenario assumes severe damage to the Colorado River Aqueduct (CRA), the California Aqueduct, and the Los Angeles Aqueduct (LAA). A complete description of probable seismic damages and repair durations is presented in Metropolitan's *"Seismic Resilience Water Supply Task Force Report No. 1536"* dated June 2017 (http://www.mwdh2o.com/PDF_About_Your_Water/Report1536_Final.pdf).

Table 1 presents a summary of the estimated outage duration under the earthquake scenario based on the nature of damage for each of the aqueducts.

Table 1
Estimated Outage Duration for Imported Supply Aqueducts (M 7.8 earthquake)

Aqueduct	Estimated Outage Duration
Colorado River Aqueduct	2 to 6 months (recovery of 80% CRA capacity) 3 to 5 years (recovery of 100% CRA capacity)
California Aqueduct: East Branch	12 to 24 months
California Aqueduct: West Branch	6 to 12 months
Los Angeles Aqueduct	18 months

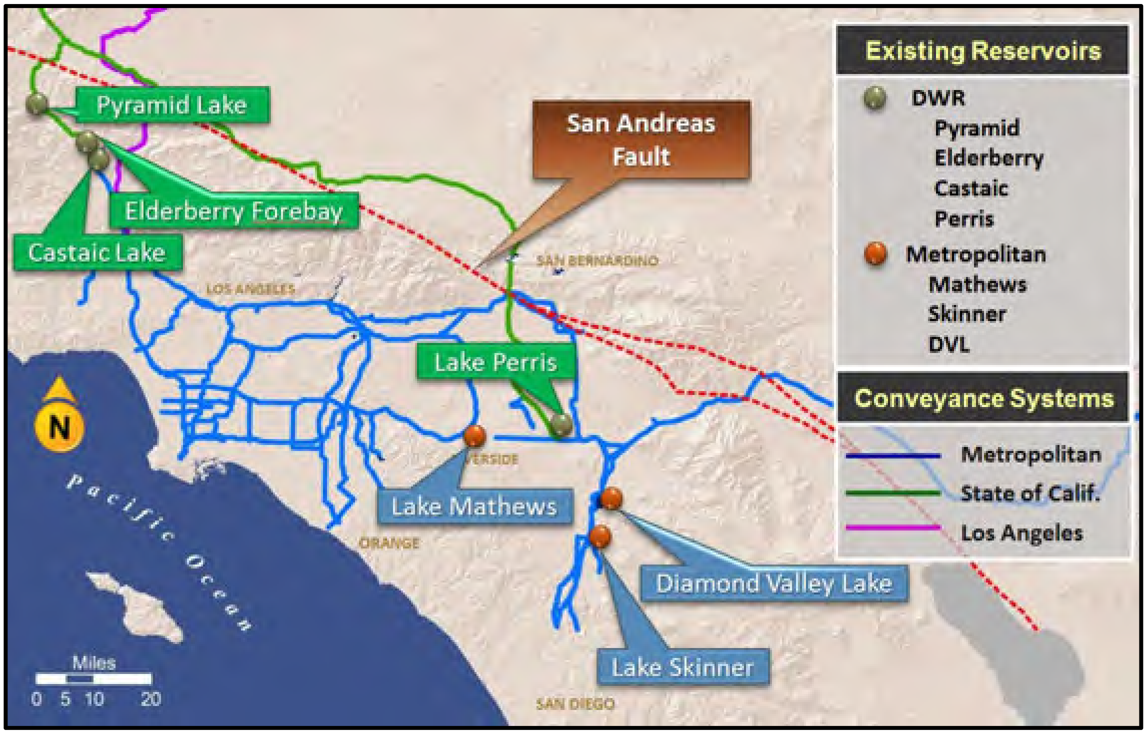
Operational Flexibility

Metropolitan's integrated system provides operational flexibility. The flexibility in Metropolitan's distribution system was demonstrated during the unprecedented drought of 2014-2016. Facing consecutive years of low SWP supplies, Metropolitan pushed CRA and Diamond Valley Lake (DVL) supplies to areas that Metropolitan normally serves only with SWP supplies or at higher blend of SWP. Figure 1 illustrates Metropolitan's operations during that period of extraordinary drought when SWP supplies were at a historic low. Metropolitan can utilize much of the same operational flexibility in its distribution system to facilitate movement of stored supplies during a prolonged outage. This flexibility combined with retail demand reduction through additional conservation and local production at appropriate levels will allow the region to meet its demands in most areas during emergency outages. Although it is not possible for Metropolitan to predict the specific damage to the system in an event of a catastrophic emergency, it seeks to ensure the most flexibility possible throughout the system to respond to different damage scenarios.

Figure 1
Metropolitan Operations during Extraordinary Drought Actions (2014-16)

During an emergency outage, previously stored imported supplies will be withdrawn to meet the region's supplemental water needs. Emergency Storage is used first and dry-year storage is then used, if necessary and available. Figure 2 shows the locations of existing DWR and Metropolitan surface reservoirs in various parts of the region.

Figure 2
Existing DWR and Metropolitan Surface Reservoirs
South of the San Andreas Fault



Metropolitan can draw from emergency supplies stored in Castaic Lake, Elderberry Forebay, and Pyramid Lake during an outage to serve the western areas that previously received SWP water. A limited quantity of CRA supplies could also be available to these areas when 80 percent of the CRA capacity is restored within six months to supplement emergency water needs in this area. Metropolitan can also supply up to 50 cfs of water from Greg Avenue Pump Station to the far western portion of its service area while repairs to the three aqueducts are being completed. This operational flexibility is also useful in the event that stored water was not adequate within the Castaic/Pyramid system.

Metropolitan can draw from emergency supplies stored in DVL, Lake Skinner, Lake Mathews, and Perris Lake during an outage to serve the eastern areas that previously received CRA and SWP water. When the CRA is restored to 80 percent of capacity within six months, it could provide up to 960,000 acre-feet per year (AFY) of imported water to the region. This volume is more than the 15-year historic average (2003 to 2017) CRA delivery of approximately 885,000 AFY and more than the 2015 IRP CRA delivery target of 900,000 AFY for a normal year. During outages, portions of the eastern area are expected to continue to receive treated CRA and/or stored emergency supplies through Weymouth. Some areas that normally receive SWP water from the East Branch may be served by delivering DVL water to Mills through the Inland Feeder/Lakeview Pipeline intertie. Metropolitan recognizes that there are currently no options to supply the Rialto Pipeline from emergency storage reservoirs during an outage of the East Branch of the California Aqueduct. However, water stored in Silverwood Lake (which is not included in Metropolitan's Emergency Storage portfolio) could be available to supply the Rialto Area as soon as repairs to damaged penstocks and pipelines downstream of Silverwood Lake are completed. This could likely require less time than repairs to the East Branch north of Silverwood Lake. In addition, other potential options to supply the Rialto region include several conceptual pump back operations and increased groundwater storage and extraction capacity for emergencies.

Metropolitan will continue to deliver treated water from stored emergency supplies during an outage and from imported supplies upon service restoration. Four of Metropolitan's five water treatment plants have redundant power feeds from the power provider. A project is currently underway to also equip the fifth plant with a redundant power feed. All five water treatment plants have backup emergency generators that support all treatment processes with the exception of ozone. Disinfection using chlorine would occur when the plants are reliant on generator power for treatment operations during a loss of utility power. Metropolitan maintains a minimum 30 day supply of chlorine in the region.

Updated Outage Criteria

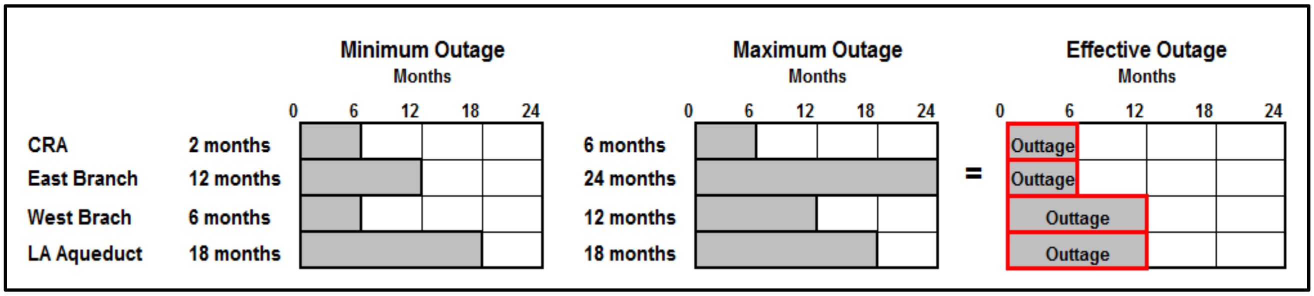
In updating the emergency outage criteria, the Workgroup considered both the duration of aqueduct repair based on the nature of potential seismic damage and recently demonstrated operational flexibilities of Metropolitan's distribution system.

Figure 3 shows the range of outage durations for the CRA, California Aqueduct East and West Branches, and the LAA. The effective outage period is then derived by accounting for the estimated durations of repair for each regional aqueduct coupled with the operational ability to deliver supplies to the area served by that specific aqueduct. In updating the outage period, the Workgroup considered the following operational assumptions:

- The estimated outage duration and repair of LAA under the earthquake scenario is 18 months. However, when the West Branch comes back in service within 12 months, it can supply water to LADWP through LA-35 while the LAA repairs continue.
  - ***Assumed outage period: 12 months for member agencies receiving supplies from West Branch and LAA.***
- The estimated outage duration and repair time of East Branch is 12 to 24 months. However, when 80 percent of the CRA capacity comes back in service within 6 months, CRA supplies would be available to many Metropolitan member agencies that normally receive SWP supplies. Thus, some areas that are normally served with water imported through the East Branch may be served with water imported through the CRA, using delivery of DVL water to Mills and several other options that should be evaluated in the Rialto area discussed above.
  - ***Assumed outage period: 6 months for member agencies receiving supplies from CRA and East Branch (with the exception of Rialto agencies).***

Using these assumptions, the effective new outage criteria presented in Figure 3 calls for storing supplemental supplies for 12 months in the West Branch and LAA areas (supplied by emergency storage in Castaic, Pyramid, and Elderberry) and 6 months in the CRA and East Branch areas (supplied by emergency storage in Perris, Skinner, Mathews, and DVL). In addition to the 12-month stored emergency supplies, West Branch areas could also be served with limited amounts of CRA supplies within 6 months to help meet demands in areas normally served with SWP supplies and higher blend areas. It is not possible to predict the specific damage to the system as a result of a catastrophic event. Therefore, system flexibility is important to ensure all supplies may be moved, if necessary and possible.

Figure 3
Updated Emergency Outage Criteria



Retail Demand Cut Back Criteria

Demand Projection

The first step in calculating the Emergency Storage is to determine the total amount of emergency retail water demand at the member agency level. The Emergency Storage is intended to reflect estimated supplemental water demands on Metropolitan during an emergency outage now updated to a period of 6 or 12 months. Thus, the aggregate of emergency retail demand is used to determine the aggregate supplemental demands on Metropolitan during such emergency, which excludes non-firm deliveries. Those deliveries are assumed to be suspended during an outage, as shown in Table 2.

Calculations of the emergency retail demand are provided for the year 2018 based on forecasts reported in the 2015 IRP. The retail demands in Table 2 were calculated at the member agency level. The numbers shown in this table represent the aggregate total retail demand (M&I and agricultural), replenishment, and seawater barrier demands over the emergency outage period considered. The total retail demands are based on forecasts from the Southern California Association of Government's (SCAG) 2012 Regional Transportation Plan/Sustainable Community Strategy and from the San Diego County Association of Government's (SANDAG) Series 13: 2050 Regional Growth Forecast (October 2013) forecast. The SCAG and SANDAG regional growth forecasts are the core assumptions in the econometric demand modeling for Metropolitan's 2015 IRP.

Table 2
Firm Retail Demands (Average Year)
(Acre-Feet)

	2018 Demands for 6-months and 12-months(1)
Total Retail Demand	2,735,617
Replenishment	(197,103)
Seawater Barrier	(52,000)
Firm Retail Demand	**2,486,514**

Note: (1) Retail demands are assessed for the 6-month outage period for member agencies receiving supplies from CRA and East Branch, and 12-months for member agencies receiving supplies from West Branch and LAA (see Attachment A).

Reduced Retail Demands during Emergency Outage

The next step in calculating the emergency storage demand on Metropolitan is to subtract a percentage reduction, or cutback, in water use from the retail demands. For illustrative purposes, Table 3 below shows the resulting reduction in retail demands during emergency outage after a cutback of 25 percent is imposed on the 2018 average condition retail demands. The retail demands in Table 3 are calculated at the member agency level. The numbers represent the aggregated total over the emergency outage period considered.

The assumption of a 25 percent retail demand cutback is a planning criterion that is consistent with previous Metropolitan studies that showed overall outdoor water use at approximately 30 percent. That cutback criterion is also consistent with the Public Policy Institute of California (PPIC) report *(Building Drought Resilience in California's Cities and Suburbs, June 2017)* based on lessons learned during drought. A higher level of austerity, public awareness, and a likely emergency declaration during an outage may support a higher cut back through additional conservation actions.

Table 3
Retail Level Emergency Demands (Average Year)
(Acre-Feet)

	2018 Demands for 6-months and 12-months[1]
Firm Retail Demand	2,486,514
25% Reduction (Cutback)	(621,629)
100% IAWP Reduction	N/A
Retail Demand during Emergency	**1,864,885**

Note: (1) Retail demands are assessed for the 6-month outage period for member agencies receiving supplies from CRA and East Branch, and 12-months for member agencies receiving supplies from West Branch and LAA (see Attachment A).

Local Production Level Criteria

The next step in calculating the Emergency Storage is to determine the amount of local supplies (local production of in-region supplies and release from local storage) available to meet retail demands at the member agency level. The local production represents the member agencies' highest potential production from the various types of supplies available within their service areas with consideration to each member agency's supply, capacity, and demand limitations. For this evaluation, the year 2018 forecast from the 2015 IRP is initially used to estimate the local production for the 6-month and 12-month emergency outage periods. In addition, Metropolitan also considered the factors that could limit each member agency's local supplies production. These include:

- Supply limitation – Considers all supplies available during an emergency outage (including additional groundwater rights, allowable over pumping in the basin, or similar mechanism if available and needed)
- Capacity limitation – Considers all available local production capacity (including extra well capacities to produce the any additional groundwater supplies if available and needed)
- Demand limitation – Considers the projected demand during the outage period (to determine the needed supplies from local and supplemental sources)

The Unused Local Production represents the aggregated production of individual member agencies above what is needed to meet their demands. In contrast, the Effective Local Production is the aggregated amount of locally available supplies that are produced to meet the reduced retail demands during an emergency outage. The Effective Local Production is derived by subtracting Unused Local Production from the aggregate total local production. For planning purposes in determining the Emergency Storage for the region, the Effective Local Production is calculated with the assumption that locally available supplies will be used only within the producing member agency's service areas and not be used or exported to meet the demands of other agencies. However, in real emergency outages, it is likely that member agencies would implement region-wide and inter-agency coordination for the most efficient operation and use of available supplies.

As part of evaluating the Effective Local Production, Metropolitan also assessed the additional local groundwater that could be theoretically produced and local surface storage that could be reasonably available during an emergency outage. This evaluation revealed that additional groundwater supplies, while theoretically available, could not be produced due to one or a combination of limiting factors. The local surface storage, on the other hand, includes all reasonably available surface water storage that the member agency could produce and use within its service area during extended shortages. The Local Surface Storage in Table 4 includes SDCWA's calculated Emergency Storage Requirement of 20,000 AF (as reported to their Water Planning Committee in July 18, 2018) and a portion of its carryover storage. Under the Carryover Storage Policy Guidelines, included in SDCWA's Water Shortage Contingency Plan Appendix A dated August 2017, SDCWA will maintain a carryover target volume of 70,000 AF and a maximum of 100,000 AF to be utilized over five consecutive dry-years. During an emergency outage, the region will most likely draw supplies from all reasonably available storage to meet demands. This evaluation reasonably assumes that in addition to its emergency storage, one-fifth of SDCWA's 70,000 AF target carryover storage, amounting to 14,000 AF, would be available for a catastrophic emergency outage based on the low likelihood that that all carryover supplies would have been withdrawn over multiple dry-years.

Table 4 shows the aggregate total for each type of locally available supplies over the emergency outage period considered. For illustrative purposes for 2018, Table 4 also presents the local production at 100 percent, 90 percent, and 80 percent. The LAA production is excluded from this calculation because the Emergency Storage assumes the loss of all imported water supplies. The member agency local production data is included as Attachment A.

Table 4
Effective Local Production
(Acre-Feet)

	2018 Local Production for 6-months and 12-months[1]		
	At 100%	At 90%	At 80%
Groundwater	832,000	748,800	665,600
Surface Water	54,935	49,442	43,948
Local Surface Storage[2]	34,000	30,600	27,200
Recycling and GW Recovery	353,797	318,417	283,038
Seawater Desalination	25,319	22,787	20,255
Los Angeles Aqueduct	0	0	0
Other	13,100	11,790	10,480
IRP Targets[3]	18,087	18,087	18,087
Subtotal Local Production	1,331,238	1,199,923	1,068,608
Unused Local Production	(152,021)	(86,449)	(31,056)
Effective Local Production	**1,179,216**	**1,113,474**	**1,037,551**

Note: (1) Local production are assessed for the 6-month outage period for member agencies receiving supplies from CRA and East Branch, and 12-months for member agencies receiving supplies from West Branch and LAA 9 (see Attachment A).
(2) Local Surface Storage is comprised of emergency storage plus reasonably available storage above emergency.
(3) Conservation and locally available supply targets from the 2015 IRP for Year 2018.

Emergency Demands on Metropolitan

The final step in calculating the Emergency Storage is to subtract the Effective Local Production from the retail demands during an emergency outage for each member agency. The resulting difference represents the supplemental water demands on Metropolitan during an outage period This is the Emergency Storage planning level for the region. Table 5 shows the aggregated totals at varying local production levels for 2018. The table below illustrates that the emergency demand on Metropolitan, and in effect the Emergency Storage, increases as Effective Local Production decreases under the 90 percent and 80 percent scenarios.

Table 5
Emergency Demands on Metropolitan
(Acre-Feet)

	Local Production		
	At 100%	**At 90%**	**At 80%**
Retail Demand during Emergency	1,864,885	1,864,885	1,864,885
Effective Local Production	(**1,179,216**)	(**1,113,474**)	(**1,037,551**)
Metropolitan Emergency Demand	**685,666**	**751,411**	**827,334**

Sensitivity Analysis

A sensitivity analysis of retail cutback and loss of local supplies were conducted. To explore the sensitivities of the Emergency Storage from these two criteria, Metropolitan evaluated various percentages of demand cut backs and levels of local production. Table 6 shows the resulting Emergency Storage at various combinations of retail demand cutback and local production levels. This matrix of emergency storage values presents retail demand cut backs of 0 percent, 25 percent, 35 percent, and 50 percent and local production levels of 100 percent, 90 percent, and 80 percent.

Table 6
Range of Potential Emergency Storage Objectives for Year 2018
(Acre-Feet)

Local Production Level	Retail Demand Cutback			
	0%	25%	35%	50%
100%	1,176,600	685,700	513,300	294,000
90%	1,286,600	751,400	570,700	332,300
80%	1,417,900	827,300	636,300	377,300

Envelope Concept for Metropolitan's Emergency Storage Objective

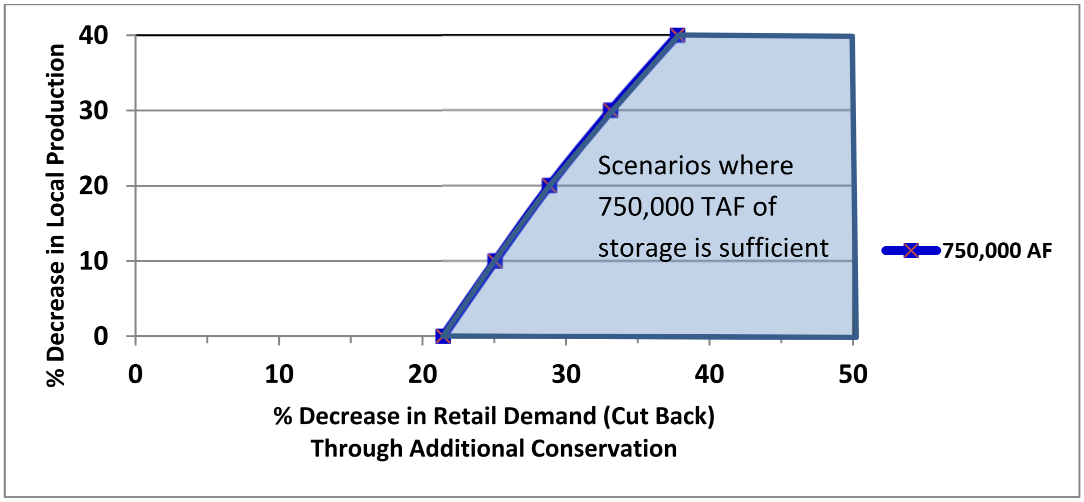
Rather than considering a specific region-wide scenario of conservation and local production loss, the Workgroup discussion led to the development of a range of emergency storage values that could provide reliability during the outage period. The concept of an envelope of solutions emerged, with the idea that an envelope of solutions will yield an appropriate Emergency Storage for the region. The Emergency Storage, in turn, could be achieved through various combinations of (1) retail demand cutback from achievable conservation and (2) local production level taking into account potential damages to local facilities. This envelope concept underscores member agencies' individual and unique situations while taking into account their inputs in identifying practicable ranges of decreases in retail demand and local production.

For the retail demand cut back, most member agencies considered the 25 to 35 percent range to be reasonable. This range is based on the level of conservation that the region was able to achieve during the recent drought. For the local production, several member agencies expected some damage to local facilities during the earthquake. In addition, Metropolitan acknowledges that retail demand cutback may also lead to reduction of non-potable recycled water use. Thus, for local production, the Workgroup focused on a range from 80 percent to 100 percent of the member agencies' reported local production in the 2015 IRP. This would allow contingency planning for uncertainties in damage to local facilities and accommodate different durations of local repairs. This is a modification from the previous assumption of full local production at the IRP level during an outage period.

As indicated in Table 6, a scenario using the criteria of 25 percent retail demand cut back and 100 percent local production level yield an estimated Emergency Storage of 686,000 AF for year 2018. However, the Workgroup focused on an envelope of alternatives for Emergency Storage that could provide reliability during the outage period. The same table matrix of values above highlights the range from 520,000 to 830,000 AF. Within this range, an Emergency Storage of 750,000 AF is recommended. This level of storage would prevent severe water shortages in the region with practicable ranges of reduced demands through conservation and plausible levels of local production during an emergency outage. Figure 4 shows that the

Emergency Storage would be sufficient to cover various combinations of practicable ranges of decreases in retail demand and local production.

Figure 4
Emergency Storage Objective derived from the Envelope Concept



Allocation of Emergency Storage in Regional Reservoirs

Once the Emergency Storage is determined, it can then be allocated to the various surface reservoirs within the region, previously illustrated in Figure 2, south of the San Andreas Fault. The total storage capacity of existing DWR and Metropolitan surface reservoirs and the allocation to emergency storage, seasonal, regulatory, and drought carryover needs are shown in Table 7 through 11. For the DWR reservoirs, the values in the tables reflect the normal maximum operating and dead pool storages indicated in the DWR report *"California State Water Project, Volume III, Storage Facilities, Bulletin 200"* dated November 1974. For this evaluation, recreational waters in DWR reservoirs are assumed to be available for emergency use during outage periods. On a short-term basis for operational purposes, storage at any specific reservoir may be below these planning levels. When this happens, the emergency storage is shifted temporarily to any of the other existing reservoirs.

Department of Water Resources Surface Reservoirs

Table 7 below shows the five major reservoirs owned and operated by DWR in or near Metropolitan's service area. Castaic Lake, Elderberry Forebay, and Pyramid Lake are located on the West Branch of the California Aqueduct. Silverwood Lake and Lake Perris are on the East Branch of the California Aqueduct. The total storage capacity of these five reservoirs is approximately 721,600 AF. When cost allocation factors from DWR Bulletin 132 Appendix B, Table B-2 are applied to the operational storage capacities, Metropolitan's share of storage in the reservoirs is equivalent to 644,400 AF.

Table 7
Allocation of Storage Capacities in DWR Reservoirs
(Acre-Feet)

Reservoir	Total Storage Capacity	Dead Storage	Storage Paid by Others	Storage Paid by Metropolitan
Pyramid Lake	169,900	4,800	7,000	158,100
Castaic Lake	323,700	18,600	12,500	292,600
Elderberry Forebay	28,200	800	1,100	26,300
Silverwood Lake	73,000	4,000	24,300	44,700
Lake Perris	126,800	4,100	0	122,700
Total	**721,600**	**32,300**	**44,900**	**644,400**

Source: California Department of Water Resources (1974). California State Water Project, Volume III, Storage Facilities, Bulletin 200, pages 294, 340, 367, 407, and 408.

From 2005 to 2017, DWR temporarily lowered the maximum storage elevation in Lake Perris because of seismic safety issues. This elevation change resulted in reduction of storage available to Metropolitan in Lake Perris, which was taken into account in past emergency storage evaluations. In 2018, the seismic retrofit of Lake Perris was completed, which restored storage to its full capacity. For purposes of the emergency storage analysis provided herein, it is assumed that 122,700 AF could be available to Metropolitan from Lake Perris. Furthermore, the Monterey Amendment, executed by the DWR and most of the State Water Contractors in 1995 and 1996, addresses the allocation of SWP water in times of shortage and deals with a number of other issues that facilitate more water management flexibility for Contractors.

Table 8 shows the distribution of Metropolitan's emergency storage in DWR reservoirs. Of the total 644,400 AF of storage in DWR Reservoirs that is for Metropolitan use, almost 381,000 AF of this amount is allocated to emergency storage and the remaining 263,600 AF is for seasonal, regulatory, and dry-year storage.

Silverwood Lake capacity does not add to the total Emergency Storage Capacity because of its location outside of major earthquake faults assumed for the emergency storage calculation methodology. However, Silverwood Lake could be available after a seismic event upon restoration of any damaged distribution system components downstream of the lake. It is expected that the portion of the distribution system downstream of the lake could be restored more expeditiously after an event due to its relatively short length, accessibility of the pipelines, and redundancies in the system.

Table 8
Allocation of Emergency Storage in DWR Reservoirs
(Acre-Feet)

Reservoir	Metropolitan Storage Capacity	Seasonal, Regulatory and Dry-Year Storage	Emergency Storage Capacity
Pyramid Lake	158,100	0	158,100
Castaic Lake	292,600	153,900	138,700
Elderberry Forebay	26,300	0	26,300
Silverwood Lake	44,700	44,700	0
Lake Perris	122,700	65,000	57,700
Total	**644,400**	**263,600**	**380,800**

Metropolitan Surface Reservoirs

Table 9 shows the allocation of storage resources in Metropolitan's three major surface reservoirs, Lake Mathews, Lake Skinner, and DVL. These three reservoirs provide approximately 1,036,000 AF of total storage capacity to Metropolitan's service area.

Lake Mathews has available storage of approximately 178,500 AF and distributes CRA water to Riverside, Orange, Los Angeles, and San Bernardino counties. Lake Skinner has approximately 43,800 AF of available storage and receives CRA and SWP water for distribution to Riverside and San Diego counties. DVL is Southern California's largest reservoir with approximately 810,000 AF of total capacity, with 798,500 AF of available capacity to meet demands and provide emergency water supplies.

Table 9
Allocation of Storage Capacities in Metropolitan Reservoirs
(Acre-Feet)

Reservoir	Total Storage Capacity	Dead Storage	Available Capacity
Lake Mathews	182,000	3,500	178,500
Lake Skinner	44,000	200	43,800
Diamond Valley Lake	810,000	11,500	798,500
Total	**1,036,000**	**15,200**	**1,020,800**

Table 10 shows the components of storage, including emergency, seasonal, regulatory, and dry-year storages, for all of Metropolitan's reservoirs. Under the recommended Emergency Storage of 750,000 AF, out of the roughly 1,021,000 AF of available Metropolitan storage capacity, approximately 369,200 AF are reserved for emergency storage, with the remaining storage capacity available for seasonal, regulatory, and dry-year storage.

Table 10
Allocation of Emergency Storage in Metropolitan Reservoirs
(Acre-Feet)

Reservoir	Available Capacity	Emergency Storage Objective at 750 TAF	
		Seasonal, Regulatory and Drought Storage	Emergency Storage
Lake Mathews	178,500	100,000	78,500
Lake Skinner	43,800	10,000	33,800
Diamond Valley Lake	798,500	541,600	256,900
Total	**1,020,800**	**651,600**	**369,200**

Emergency Storage Capacities in DWR and Metropolitan Reservoirs

The Emergency Storage presented in this white paper is evaluated based on regional aggregation of retail demands and locally available supplies within the service area. The resulting Emergency Storage is assumed to be distributed amongst the available capacities within the existing DWR and Metropolitan surface reservoirs. During an outage, Metropolitan delivers supplement water to member agencies from previously stored emergency supplies, and dry-year supplies if necessary and available, based on the most effective operation of the distribution system under emergency conditions.

Table 11 presents the storage of emergency supplies in DWR Reservoirs, Lake Mathews, and Lake Skinner to be fixed quantities, with any remaining need reflected as changes in DVL's emergency storage allocation under the recommended 750,000 AF of Emergency Storage.

Table 11
Allocation of Emergency Storage in Existing Reservoirs(1)
(Acre-Feet)

Reservoir	Emergency Storage Objective at 750 TAF
Pyramid Lake	158,100
Castaic Lake	138,700
Elderberry Forebay	26,300
Lake Perris	57,700
Lake Mathews	78,500
Lake Skinner	33,800
Diamond Valley Lake	256,900
Total	**750,000**

Note: (1) This allocation provides operational guidance but does not create a minimum emergency storage volume in any single reservoir.

Conclusion

This white paper summarizes the progress to date of the Workgroup coordination process to estimate a planning objective for the region's emergency storage, as part of Metropolitan's ERSP. Evaluating the Emergency Storage involves the regional aggregation of retail water demands and locally available supplies within the service area. It also accounts for the member agencies' unique situations in identifying practicable ranges of additional conservation actions that could yield decreases in retail demand and levels of local production that could be accomplished during emergency outage.

Under the new envelope concept, the Workgroup focused on an acceptable range of regional emergency storage values from 520,000 to 830,000 AF. **Based on feedback to date, staff recommends an Emergency Storage of 750,000 AF.** This level of storage would prevent severe water shortages for the region with practicable ranges of water demand reduction achievable conservation actions and plausible levels of local production. This recommended regional emergency storage is assumed to be distributed amongst the available capacities within the existing DWR and Metropolitan surface reservoirs, as shown in Table 11.

The Emergency Storage presented in this white paper is a regional planning objective. It is an estimate for the amount of Metropolitan water that the region targets to store in preparation for a catastrophic earthquake event. This evaluation of Emergency Storage is not intended to set a basis or a policy for allocating or apportioning storage for each individual member agency.

The Workgroup proposes that this storage objective be revisited periodically, possibly following the completion of a new IRP. Metropolitan also considers spatial distribution for the purpose of determining generally where to store its emergency water. However, specific operations during an emergency will depend on the actual conditions at that time. Since member agency demands for supplemental water will be met through deliveries of supplies from storage, evaluation of spatial distribution of storage and most effective operation of the distribution system will be accomplished as part of Metropolitan's continued efforts and coordination within the ERSP's storage portfolio evaluation or other regional planning processes.

Note: Member agency local production are approximation for year 2018 based on 2015 IRP and are estimated for the outage periods indicated.
This table shows individual member agency estimates used to develop Metropolitan's Emergency Storage Objective for the region.
For agencies along the Rialto Pipeline, see discussion on pages 5-6 related to system limitations for receiving CRA supplies.
Local surface storage includes all reasonably available surafce storage that the member agency could produce and use within its service area. Includes SDCWA's calculated ESP storage requirement reported to their Water Planning Committee in July 2018 and a portion of their target carryover storage as discussed in page 9.

Appendix 9

SEISMIC RISK ASSESSMENT AND MITIGATION PLAN

Appendix 9
SEISMIC RISK ASSESSMENT AND MITIGATION PLAN

Beginning January 2020, CWC Section 10632.5 mandates UWMPs to include a seismic risk assessment and mitigation plan to assess the vulnerability of each of the various facilities of a water system and mitigate those vulnerabilities. For Metropolitan, this required assessment and plan are accomplished as part of developing its resilience strategy and are presented in detail in Metropolitan's seismic resiliency reports attached to this appendix.

Over its nearly 90-year history, Metropolitan has been proactive in mitigating seismic risks posed to its expansive infrastructure, as well as improving its ability to maintain (or quickly restore) water deliveries following a major earthquake. This ability to mitigate seismic risks and maintain (or quickly restore) water deliveries following a seismic event is referred to as "seismic resilience." Metropolitan's holistic strategy for seismic resilience follows a "defense in depth" multi-layered approach for managing risk. Metropolitan's Seismic Resilience Strategy has three primary objectives:

1. Provide a diversified water supply portfolio, system flexibility, and emergency storage
2. Prevent damage to water delivery infrastructure in probable seismic events and limit damage in extreme events
3. Minimize water delivery interruptions through a dedicated emergency response and recovery organization

Metropolitan's Seismic Resilience Strategy is implemented through four components that encompass the various internal functions that promote the organization's seismic resilience objectives. These components are supplemented by Metropolitan's commitment to inter-agency coordination when preparing and responding to a seismic event and other emergencies. The strategy is shown below in Figure A.9-1.

Figure A.9-1
Seismic Resiliency Strategy

A brief description of the components of Metropolitan's Seismic Resilience Strategy and examples of their implementation are provided below.

Planning

The goals of the planning component are to develop and maintain a diversified water resource portfolio; provide a flexible system that allows for operational changes to handle variations in water supply, planned or unplanned system outages; and to maintain adequate emergency storage supplies. Metropolitan has developed a diverse water resource portfolio through the enactment of various exchange and water banking programs. These water supply programs are described in detail in Section 3 and Appendix 3. In addition to existing supply programs, development of the Regional Recycled Water Program would provide Metropolitan with an additional water resource and would be strategically located on the coastal side of the San Andreas Fault. Metropolitan also strives for regional seismic resilience by incentivizing local agencies to develop increased conservation, recycling, storage, and other water management programs.

As Metropolitan expanded its system over the years, it has continually improved the flexibility of the system to handle changes in water supply or pipeline or facility outages. One example of Metropolitan's system flexibility is the Common Pool service area, which can be supplied by the Jensen, Weymouth, or Diemer water treatment plants. Additionally, Metropolitan has constructed its system such that most of the service area can be supplied by either Colorado River or State Water Project supplies.

Metropolitan's imported water supplies from the CRA and SWP East and West Branches cross the San Andreas Fault (SAF) Zone prior to reaching Metropolitan's service area. A major earthquake on the SAF has the potential of damaging all three aqueducts and disrupting imported supplies for up to six months. Metropolitan constructed Diamond Valley Lake (DVL) on the coastal side of the fault to mitigate the potential impacts of a major SAF earthquake to its service area. Completion of DVL nearly doubled Metropolitan's available surface water storage in the region and, along with other local reservoirs, is used to maintain 6 to 12 months of emergency water storage supply. Water from DVL can supply four of Metropolitan's five regional water treatment plants.

Engineering

The goal of the engineering component is to assess and mitigate seismic risk to individual facilities, and the system. This is accomplished through Metropolitan's Seismic Resilience of Structures Program, the Seismic Resilience of Pipelines Program, the Dam Safety Program, and special seismic assessments.

Seismic Resilience of Structures

Metropolitan's program to increase the seismic resilience of structures is an ongoing program with the goal of protecting life safety and critical infrastructure to minimize water delivery interruptions following a seismic event. The initial program focused on evaluating the seismic risk of above ground structures (e.g., water treatment plants) constructed prior to 1990 and upgrading structures to mitigate the risk when found to be seismically deficient. The program has recently expanded to include post-1990 structures due to the progress made on the initial list of structures. Examples of seismically upgraded facilities include the Colorado River Aqueduct pump plant buildings, the Weymouth East and West Wash Water Tanks, and the Diemer and Jensen Administration Buildings.

Seismic Resilience of Pipelines

Metropolitan's conveyance and distribution system has been built in conformance with standards and practice at the time of design. In keeping with the goals of the Seismic Resilience Strategy, Metropolitan is developing seismic design criteria for new pipelines based on current state of practice, geotechnical and seismicity criteria, operating conditions, and asset management strategies. The planned design approach for new pipelines will be to establish performance criteria, identify seismicity and ground conditions along the alignment, and design the pipeline to resist damage from ground shaking and deformation. Specialized pipe joints and sections can be designed to accommodate ground deformation from fault displacement or liquefaction. For existing pipelines, seismic resilience will be incorporated as a component of pipeline rehabilitation projects. Metropolitan will evaluate each upgrade individually to balance risk, performance, and cost. Metropolitan's Casa Loma Siphon Barrel No. 1 Seismic Upgrade Project is an example of the organization incorporating seismic design in the rehabilitation of existing pipelines. The existing siphon, which crosses a segment of the San Jacinto Fault Zone and is subject to long-term subsidence, will be replaced with earthquake-resistant ductile iron pipe. The pipe joints are designed to accommodate ground displacement without failure to allow for continued service following an earthquake.

Dam Safety Program

Metropolitan has an ongoing Dam Safety Initiatives Program that has initiated several plans to improve Metropolitan's dam seismic safety and earthquake readiness. These initiatives are being coordinated with the California Division of Safety of Dams (DSOD) and Office of Emergency Services and include the following:

- Ongoing preparation of Emergency Action Plans, including inundation maps
- Performing training exercises at the dam site to test processes during a seismic event
- Providing training and guidance on overall dam safety
- Reviewing operation and maintenance methods for reservoir drawdown and operations after a seismic event
- Updating guidelines and procedures on protection against seismic risk
- Establishing a strong communications system on seismic information
- Performing structural strengthening of dams, including rehabilitation and improvement of spillways and inlet/outlet towers such as Lake Skinner Outlet Tower
- Improving dam safety instrumentation, monitoring, and reporting capabilities

Special Seismic Assessments

Metropolitan conducts special seismic assessments to increase understanding of the vulnerability of the organization's assets and operations to various seismic hazards. The studies focus on hazards specific to individual facilities or the system as a whole and identify options to mitigate the risks posed by the hazards. In addition, the studies support emergency response training and planning for future earthquake events by estimating the magnitude of damage that may occur from various seismic events. The following is a list of some of the reports that Metropolitan has completed:

- Liquefaction Susceptibility Mapping for the Metropolitan Water District of Southern California's Feeder System (Report No. 1625), Carollo Engineers, Inc., 2019.

- Colorado River Aqueduct – San Gorgonio Pass Seismic Event Vulnerability Study (Report No. 1484), GeoPentech, July 2014.
- Potential Effects of Southern California Seismic Events on Metropolitan Water Deliveries (Report No. 1335), Metropolitan Facility Planning staff, January 2009.

Operations

The goal of the operations component is to maintain effective emergency planning and response capabilities. This is accomplished through maintaining an effective Emergency Response Organization, conducting routine emergency response training exercises, and maintaining emergency construction capabilities.

Metropolitan's Emergency Response Organization (ERO) is comprised of over 200 predesignated employees who work in the Emergency Operations Center (EOC), the Incident Command Posts, or the field during emergencies. ERO staff has completed specialized training that meets State and Federal requirements. Metropolitan's emergency response structure follows the National Incident Management System (NIMS) and the State of California's Standardized Emergency Management System (SEMS).

In addition to specialized NIMS training, Metropolitan staff routinely participate in emergency response training exercises that are often based on a postulated seismic event. In 2019, Metropolitan started a new five-year emergency exercise plan that will allow all member agencies to participate in at least one of Metropolitan's annual emergency exercises. The first of these exercises was a tabletop exercise for the Orange County member agencies on August 29, 2019, which focused on a hypothetical incident at the Diemer Water Treatment Plant.

Metropolitan has conducted over 100 exercises since February 2018. This included two large functional emergency exercises for the EOC and multiple tabletop exercises, workshops, and seminars for the 12 Incident Command Posts located at the water treatment plants, conveyance and distribution facilities, and other strategic locations in Metropolitan's service area.

Metropolitan maintains the necessary staffing, materials, and equipment to respond to two simultaneous pipeline breaks. The Machine Shop and Coating Shop at La Verne are available to fabricate pipe sizes up to 12 feet in diameter, and Metropolitan's construction forces have the necessary equipment and expertise to make the repairs in-house. In addition, Metropolitan has upgraded its satellite phones to ensure communication ability following a seismic event and is in the process of installing high frequency radios at all Incident Command Posts and the Emergency Operations Center.

Reporting

Metropolitan has committed to providing annual updates to its Board of Directors on the organization's Seismic Resilience Strategy and its progress toward identified short-term and long-term goals. The organization has also committed to providing a formal report on a five-year interval summarizing accomplishments related to seismic resilience and changes in directives to the Seismic Resilience Strategy.

Inter-Agency Coordination

Improving the region's seismic resilience requires that member agencies understand the seismic risks to the imported water supplies so that they may appropriately plan on the local level. Opportunities for inter-agency coordination are provided through the Local Resources Program where Metropolitan incentivizes the development of local groundwater, recycling, and other supply resources to offset imported demands. As stated previously, Metropolitan provides member agencies the opportunity to participate in emergency response exercises. As part of a recent study, Metropolitan developed maps that define the relative liquefaction susceptibility of the region inclusive of the conveyance and distribution system and has made these maps available to member agencies. Recently, the organization updated the emergency storage goals through several workshops in coordination with member agencies.

Metropolitan is also a member of the Seismic Resilience Water Supply Task Force, along with the California Department of Water Resources (DWR) and the Los Angeles Department of Water and Power (LADWP). As the owners of the three conveyance facilities that provide imported water to the region, Metropolitan, DWR, and LADWP have recognized the importance of coordinating responses following a major seismic event that disrupts the imported water supplies. Each agency has provided an overview of the seismic risk to their respective systems and are in the process of developing a Water Mutual Assistance Agreement to formalize the coordination efforts following a major earthquake that disrupts service to the imported water supplies.

Metropolitan's Seismic Resilience Reports

The various components of Metropolitan's resilience strategy summarized above are described in detail in Metropolitan's Seismic Resilience Report First Biennial Report (February 2018) and Seismic Resilience Report 2020 Update (February 2020) presented as part of this appendix. These reports are also available on Metropolitan's website:
http://mwdh2o.com/AboutYourWater/Planning/Seismic-Resilience-Report/

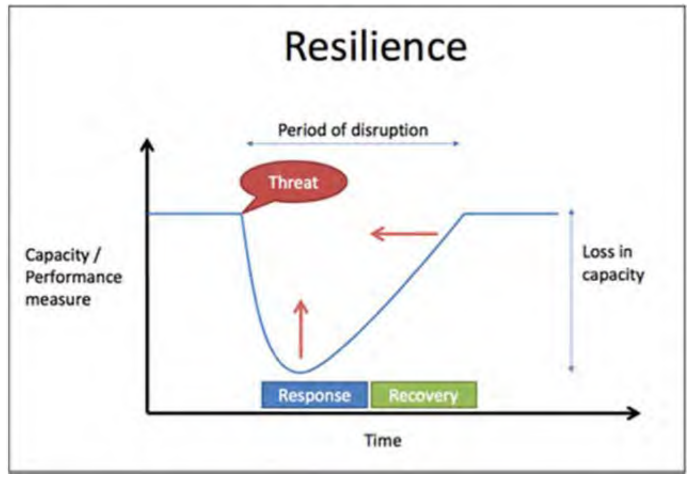
EXECUTIVE SUMMARY

The ability to maintain, or quickly restore, water deliveries after a seismic event.

--Definition of "Seismic Resilience" for a water agency

An interruption in a key lifeline service such as water delivery can be devastating to a community's recovery after an earthquake. As the agency responsible for delivering imported water to over 19 million people in one of the world's most seismically active regions, The Metropolitan Water District of Southern California (Metropolitan) has made substantial efforts to minimize the impact of a major earthquake on the people and businesses within its service area. In 2017, Metropolitan refined and formalized its approach for addressing seismic resilience by fully integrating its planning, engineering, operations, and reporting functions.



This report documents Metropolitan's integrated Seismic Resilience Strategy, reports on key historic achievements, and communicates near-term goals aimed at further enhancing the seismic resilience of Metropolitan's infrastructure and water deliveries.

Seismic Resilience

"Resilience" is broadly defined as the ability of a system to absorb and rebound from shocks. The more resilient a system is, the smaller the impact will be that any given shock will have on the system, and the shorter the duration of recovery will be. Using the broad definition of resilience as a baseline, Metropolitan defines "seismic resilience" as the ability to maintain (or quickly restore) water deliveries following a seismic event. The more prepared a water agency is for earthquakes, and the more effective its emergency response capabilities are, the less impact the event will have on water deliveries to its customers.

Metropolitan's Seismic Resilience Strategy

Metropolitan's Seismic Resilience Strategy is a multi-faceted approach to prepare for and respond to seismic events. It involves close, formal coordination within the Metropolitan organization and with other owners of imported water conveyance systems that cross the Southern San Andreas Fault.

Coordination within Metropolitan and its member agencies focuses on diversifying water resources; enhancing operational flexibility; providing adequate emergency water supplies; and identifying and addressing infrastructure and system vulnerabilities. This coordination also involves development of effective emergency response capabilities.

The coordination with other owners of imported water conveyance systems is through a multi-agency task force. The members of this task force, which includes the California Department of Water Resources

(DWR) and the Los Angeles Department of Water and Power (LADWP) as well as other State and water industry organizations, work together to evaluate the unique seismic vulnerabilities of Southern California's imported water systems.

In addition to the coordination elements, Metropolitan's Seismic Resilience Strategy includes a reporting component to increase transparency and accountability. Each year, Metropolitan staff will update its Board of Directors on recent achievements and near-term goals. Every two years, a written report will be prepared to document these items.

Water is recognized as a critical resource, but having sufficient water available following an earthquake is essential. Seismic resilience has a goal that in most scenarios, water will be available for the vast majority of people and business affected by the event and for essential post-earthquake activities such as fire suppression.

Conclusion

Metropolitan's strategy for seismic resilience has evolved over time and has benefited from the lessons learned from major seismic events around the world. Because of this strategy, significant improvements in the overall seismic resilience of Metropolitan's water system have been made in each of the following key areas: water resource diversity, operational flexibility, emergency water storage capacity, resilience of existing infrastructure, and emergency response capabilities.

Metropolitan has also established a number of near-term goals within each of the planning, engineering, and operations components of seismic resilience that will further enhance this multi-layered approach.

Metropolitan's refined Seismic Resilience Strategy approach will maintain a clear and effective focus on long-term efforts, clearly communicate program achievements and goals to the Board, and provide member agencies with more clarity regarding projected seismic performance of Metropolitan's infrastructure.

SECTION 1 INTRODUCTION

Purpose

The Metropolitan Water District of Southern California (Metropolitan) owns and operates a complex conveyance, treatment, and distribution system that serves a 5,200-square-mile service area within an active seismic region. Over its nearly 90-year history, Metropolitan has been proactive in mitigating seismic risks posed to this expansive infrastructure, as well as improving its ability to maintain (or quickly restore) water deliveries following a major earthquake. This ability to mitigate seismic risks and maintain (or quickly restore) water deliveries following a seismic event is referred to as “seismic resilience.” Metropolitan’s strategy for seismic resilience follows a “defense in depth” multi-layered approach for managing risk: providing a diversified water resource portfolio, system flexibility, emergency water storage, robust emergency response capabilities and performing cyclical assessments of facilities and addressing identified vulnerabilities.

Over the last 20 years, Metropolitan has made significant progress in a number of key areas related to seismic resilience (see Appendix 1):

1. Increasing water supply resilience, flexibility, and emergency storage
2. Addressing the susceptibility of above-ground structures to damage from seismic events
3. Developing effective and robust emergency response capabilities

Recognizing the need for continuous improvement, Metropolitan recently re-assessed the various activities that enhance seismic resilience to refine, expand, and formalize its overall approach. The resulting Seismic Resilience Strategy is a fully integrated approach toward minimizing regional water delivery interruptions and restoring interrupted regional deliveries quickly after an earthquake.

The specific goals of the refined Seismic Resilience Strategy are to:

- Improve the integration of planning, engineering and operations activities focused on seismic resilience through regular collaborative meetings and integrated reporting
- Expand current programs to identify and address any additional seismic vulnerabilities
- Re-visit existing seismic performance objectives in light of advancements in the knowledge of earthquake hazards, earthquake engineering, and mitigation capabilities
- Document Metropolitan’s seismic resilience activities to facilitate knowledge transfer and coordination
- Improve accountability by communicating seismic resilience goals and accomplishments to Metropolitan’s Board of Directors and member agencies on an annual basis
- Enhance member agency planning efforts for emergency response and facility improvements by providing more clarity regarding the projected seismic performance of Metropolitan’s infrastructure

This document describes Metropolitan’s Seismic Resilience Strategy, summarizes key historical achievements, and communicates near-term goals that will further increase the seismic resilience of Metropolitan’s system.

Seismic Resilience Strategy Structure

Metropolitan's Seismic Resilience Strategy (see **Figure 1-1**) is a multi-faceted approach that involves coordination among key functions within Metropolitan as well as formal coordination with other owners of imported water conveyance systems that cross the Southern San Andreas Fault.

Figure 1-1: Seismic Resilience Strategy Structure and High Level Goals

As shown in the figure, the coordination within Metropolitan and its member agencies focuses on the activities of planning, engineering/design, operations/emergency response, and reporting. These efforts are complemented by the efforts of the multi-agency Seismic Resilience Water Supply Task Force (Task Force). This Task Force includes the California Department of Water Resources (DWR) and the Los Angeles Department of Water and Power (LADWP) as well as other State and water industry organizations and focuses on the unique seismic vulnerabilities of Southern California's imported water supplies.

The purpose of Metropolitan's Seismic Resilience Strategy is to enable Metropolitan to restore water deliveries to its member agencies promptly after seismic events by maintaining a diversified supply portfolio, system flexibility, and emergency storage; minimizing damage to infrastructure; and supporting a robust emergency response and recovery capability. This integrated, comprehensive approach will maintain focus on effective long-term efforts, clearly communicate program achievements and goals to the Board, and provide more clarity to member agencies regarding projected regional seismic performance to enhance local facility and emergency response planning efforts.

Report Organization

This report is organized as follows:

- *Section 2 – Background.* Provides context regarding inherent seismic risks within Southern California, a definition of seismic resilience, and a summary of how Metropolitan's seismic resilience strategy developed over time.
- *Section 3 – Planning Component.* Describes planning activities that address seismic resilience through Metropolitan's diverse water supply portfolio and adaptive management approach to managing resources, including establishing emergency storage.
- *Section 4 – Engineering Component.* Describes technical programs that identify and mitigate the seismic vulnerability of Metropolitan's infrastructure and systems.
- *Section 5 – Operations Component.* Describes the emergency response organization, training exercises, and post-event capabilities that serve to minimize the disruption of water deliveries following earthquakes.
- *Section 6 – Reporting Component.* Explains the purpose and timing of the integrated reporting component.
- *Section 7 – Seismic Resilience Water Supply Task Force Component.* Describes the purpose of the collaborative task force, recent progress, and planned activities.
- *Section 8 – Seismic Resilience Performance Objectives and Near-Term Goals.* Summarizes existing objectives of the various components of seismic resilience, describes areas where new objectives are being considered, and provides high-level goals planned to be achieved by December 2019.

WSAP	Water Supply Allocation Plan
WSDM	Water Surplus Drought Management

SECTION 2 BACKGROUND

Seismic Risk

Within Southern California, there are a number of known active faults with varying levels of activity that are capable of generating significant earthquakes and causing widespread damage to infrastructure. Modern era earthquakes that occurred within or close to Metropolitan's primary service area with a magnitude above 6.3 (M6.3) are listed in Appendix 2. In 2015, the United States Geologic Survey (USGS) released the Uniform California Earthquake Rupture Forecast Version 3 (UCERF3), which provides a forecast for the likelihood of rupture for particular earthquake faults within California. UCERF3's forecast of the likelihood of a M6.7 earthquake or greater in the next 30 years on each active fault in Southern California is shown in **Figure 2-1**. As indicated in the figure, the Southern San Andreas Fault was identified as having the highest likelihood (19%) of a M6.7 earthquake or greater in the next 30 years. UCERF3 further states that the there is a 93% chance of a M6.7 or greater earthquake occurring on one of the faults within Southern California within the next 30 years, and a 36% chance of a M7.5 or greater earthquake occurring within the next 30 years.

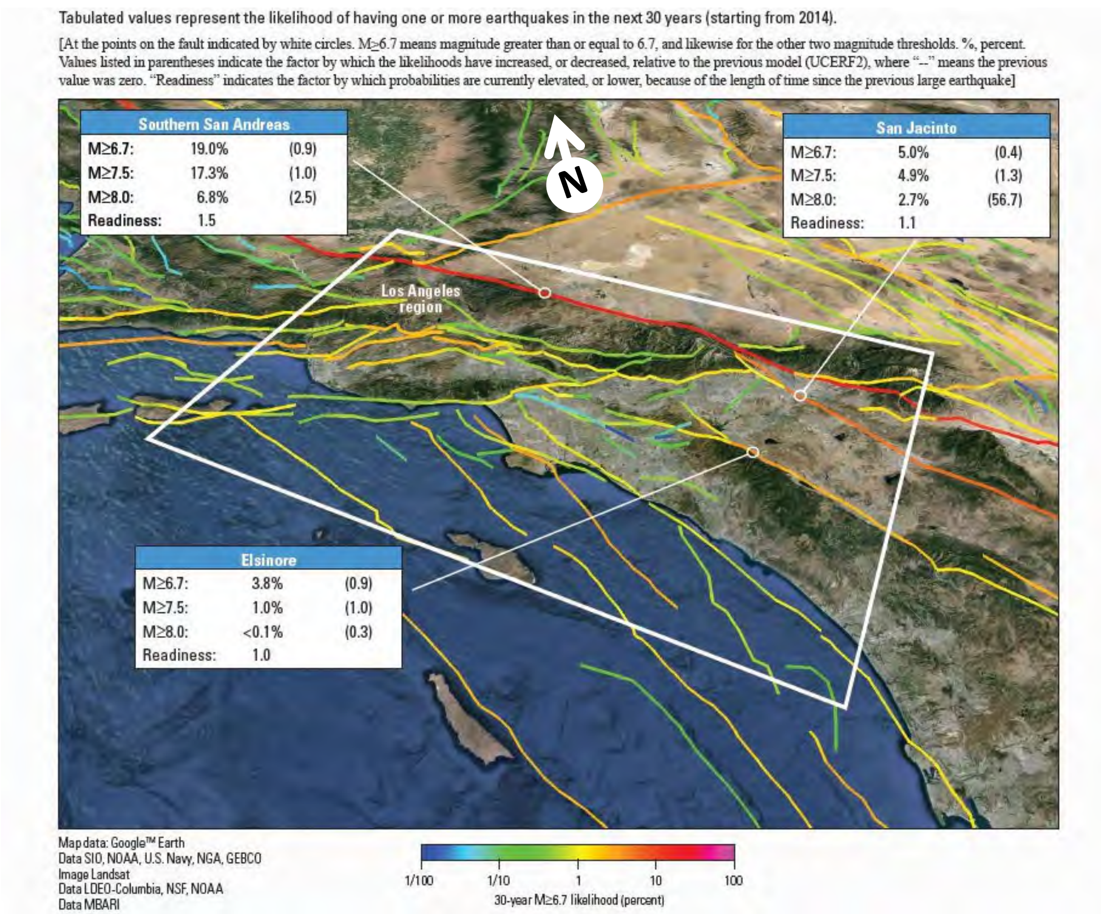

Figure 2-1: Likelihood of M6.7 or greater earthquake in the next 30 years (Source: UCERF3)

As shown in **Figure 2-2**, a significant portion of Metropolitan's infrastructure, including the Colorado River Aqueduct (CRA) and several treated water pipelines, is located near or crosses active faults.

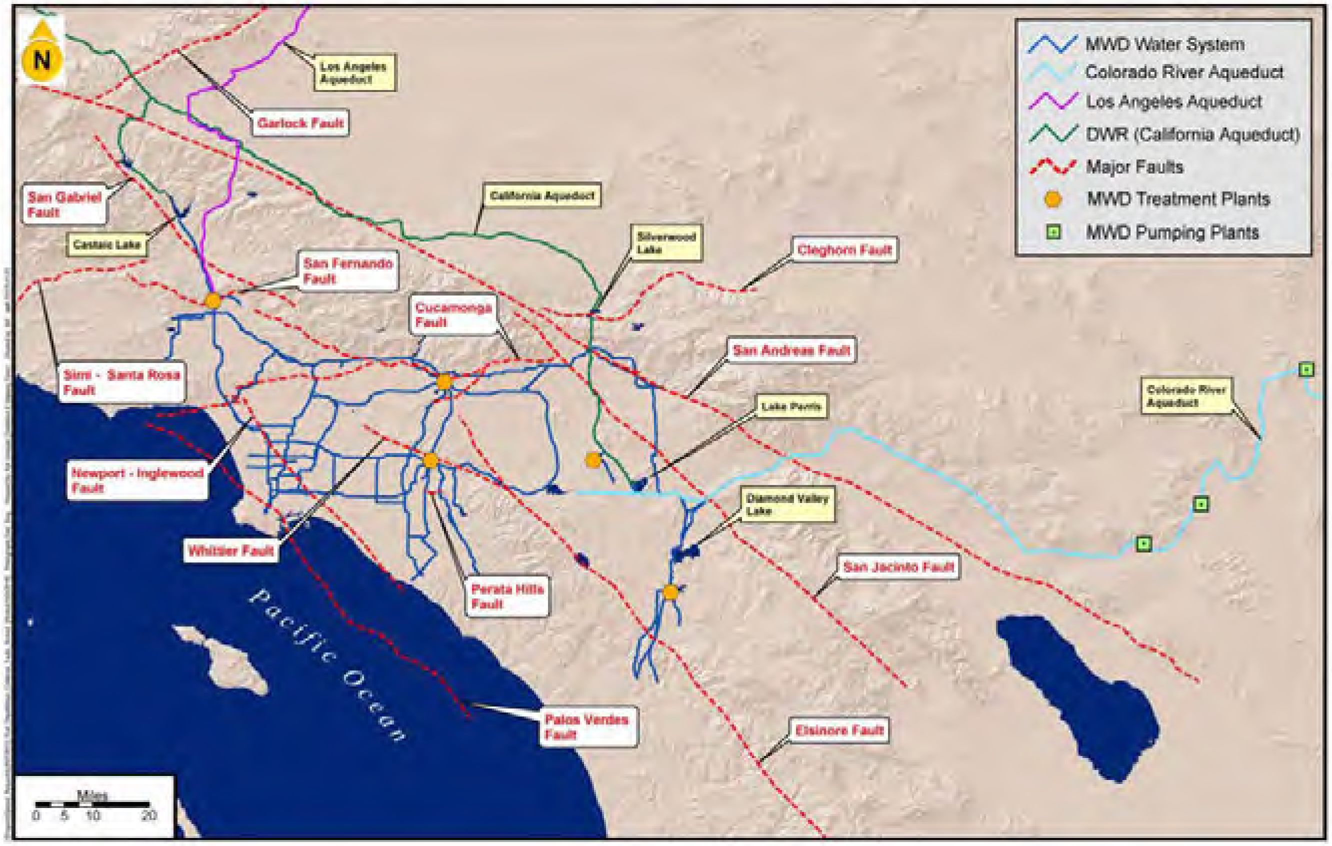

Figure 2-2: Major Earthquake Faults in Southern California

The risk of earthquake damage to Metropolitan's infrastructure from these active faults is manifested through different seismic hazards, including seismically induced ground shaking, seismically induced ground failure, and surface fault displacement.

- Seismically induced ground shaking can damage buildings, structures, aqueducts, pipelines, and tunnels. The intensity and duration of shaking at a particular location is dependent on a number of factors, including the earthquake magnitude, the distance from the earthquake epicenter, and local soil conditions.

Examples of typical effects of seismically induced ground shaking. The photograph on the left shows a damaged building from the 1994 M6.7 Northridge Earthquake. The building has essentially fallen backwards, and what was once a straight wall now appears curved. The photograph on the right shows the collapsed portion of a freeway overpass from the same earthquake.

- Seismically induced ground failure includes liquefaction, landslide, and seismic settlement. Liquefaction occurs when prolonged shaking causes saturated (water-bearing) soils to consolidate and lose their bearing capacity. This can compromise the support of structures that are constructed in these zones, including buildings and pipelines. Prolonged shaking can also lead to displacement of large areas of soil or rock, resulting in hazardous landslides and rock falls. The integrity of buildings and pipelines constructed in landslide zones can be compromised if the supporting ground experiences seismically induced failure; rockfalls can also result in structural damage due to the impacts of large boulders on structures. Seismic settlement is similar to liquefaction, except that the soil is not saturated.

Examples of seismically induced ground failures include liquefaction (left photo) and landslides (right photo) from the 2011 M6.3 Christchurch, New Zealand Earthquake and the 2016 M7.8 Kaikoura, New Zealand Earthquake, respectively.

- Surface fault displacement is usually only observed in large magnitude earthquakes but can result in devastating structural damage. The 1972 Alquist-Priolo Earthquake Fault Zoning Act prohibits construction of buildings in California within 50 feet of a known active fault trace. Therefore, surface fault displacement is generally not an issue for Metropolitan's buildings constructed after the early 1970s. However, several components of Metropolitan's conveyance and distribution infrastructure cross known active faults, including the CRA, various pipelines, and power transmission lines. These facilities are subject to damage from surface fault displacement.

Examples of surface fault displacement. The photograph on the left shows railroad tracks displaced as a result of the 1952 M7.5 Kern County Earthquake. The photograph on the right shows a field that shifted as a result of the 2010 M7.1 earthquake in Canterbury, New Zealand.

Seismic Resilience

General

According to the National Infrastructure Advisory Council (NIAC), infrastructure resilience is "the ability to reduce the magnitude and/or duration of disruptive events." The effectiveness of a resilient infrastructure or enterprise depends upon its ability to "anticipate, absorb, adapt to, and rapidly recover from a potentially disruptive event." [ref. "*Critical Infrastructure Resilience Final Report and Recommendations*," September 8, 2009]**.** This event may be man-made, such as a cyber-attack, or a natural disaster, such as a drought, flood, or earthquake.

"Seismic resilience" (see **Figure 2-3**) narrows the focus of infrastructure resilience to only earthquakes. Using the definition of "infrastructure resilience" presented above, Metropolitan has defined seismic resilience for water agencies as the ability to reduce the magnitude and/or duration of water delivery interruptions resulting from seismic events. Rather than striving to make an entire water system "earthquake-proof," seismic resilience involves setting reasonable performance goals that provide sufficient benefits that justify the corresponding investments required by both an agency and its ratepayers. Metropolitan's seismic resilience performance objectives are summarized in Section 8 of this report.

Figure 2-3: Resilience -- the ability to reduce the magnitude and/or duration of disruptive events

Applicability to Metropolitan

For over a decade, Metropolitan has had a well-defined approach to system reliability that addressed overall system resilience in five key areas: Water Supply Reliability, System Capacity, Infrastructure Reliability, System Flexibility and Emergency Response.

Seismic resilience is an essential aspect of Metropolitan's overall reliability strategy. Water deliveries are extremely crucial following earthquakes for fire suppression, for the general welfare of local residents, and for the regional economy that relies on imported water. Metropolitan's approach to seismic resilience has evolved over time to become one that is highly effective and recognized within the water industry [ref. "*Water Supply in Regard to Fire Following Earthquake*," Charles Scawthorn, Pacific Earthquake Engineering Research Center, November 2011]**.**

Metropolitan's Historical Approach to Seismic Resilience

"The aqueduct is being built for the future as well as the present, and must stand and give adequate service for an indefinitely long time."

From the "Design" Chapter of "The Great Aqueduct" book by Julian Hinds, 1938.

"It was desirable that faults be crossed at right angles, to minimize damage in the event of movement, and that some flexible type of conduit on or near the surface be used so that if repairs become necessary they will be as simple as may be…"

From "Major Problems of Aqueduct Location" by Julian Hinds, Nov. 24, 1938 Engineering News-Record.

Since its inception, and particularly during the design and construction of the CRA, Metropolitan has recognized the potential vulnerability of water infrastructure to disruptions by earthquakes. This section provides a brief overview of Metropolitan's historical approach to seismic resilience, focusing on major earthquake events in the past and lessons learned from these events.

The 1906 M7.8 San Francisco earthquake struck the coast of Northern California at 5:12 a.m. on April 18. Severe shaking was felt from Eureka on the North Coast to the Salinas Valley. Broken gas lines resulted in fires that lasted for several days due to a lack of fire supply. As a result, about 3,000 people died and over 80% of the city of San Francisco was destroyed.

The 1933 M6.7 Long Beach earthquake took place on March 10 at 5:54 P.M. Damage to buildings was widespread and between 115 and 120 people died. The earthquake highlighted the need for earthquake-resistant design for structures in California.

Post-1906 San Francisco and 1933 Long Beach Earthquakes (1930-1970)

Conveyance and Distribution System: The majority of Metropolitan's conveyance and distribution system was constructed between the 1930s and the 1970s. Historical documents regarding the planning and design of this infrastructure describe a philosophy of "permanence," which may be considered as a forerunner to "resilience." This philosophy not only took into account decades of wear and tear, routine hazards, and large storms, but also provided for seismic resilience.

Despite having no provisions within design codes, Metropolitan took proactive measures to address seismic resilience while designing the CRA. Metropolitan geologists and engineers took into account the ground shaking and deformation that had occurred along the San Andreas Fault system during the 1857 Fort Tejon earthquake and lessons learned from 1906 San Francisco earthquakes, and supplemented their understanding of regional active faults through geologic mapping and analysis of stereo aerial photographs. This led to the aqueduct being designed to cross active faults near the ground surface in inverted siphons and cross fault traces at right angles. The designers also opted for a more flexible siphon design in fault regions than the rigid monolithic concrete construction used elsewhere on the CRA, and provided extra hydraulic grade at three siphons crossing active faults (Appendix 3). These provisions were intended to minimize the adverse effects of seismically induced ground movement and to simplify access for repairs.

Metropolitan's dams are inspected on a regular basis.

<u>Water Treatment Plants</u>: Metropolitan's water treatment plants were also designed with features that enhance seismic resilience, beginning with the F. E. Weymouth Water Treatment Plant in 1940, and followed by the Robert B. Diemer Water Treatment Plant in 1963. The plants are modular in design and incorporate redundancy of key components. They are also situated strategically to maximize gravity flow to a majority of the distribution system.

Photo of the 120-inch Froriep Vertical Turning Lathe (above) and the 5-inch G&L Horizontal Boring Mill (below) in the La Verne Machine shop.

<u>Dams and Reservoirs</u>: Metropolitan began a Safety of Dams program many years before formal reporting was required by the California Division of Safety of Dams (DSOD). Staff regularly inspects Metropolitan's dams for vulnerabilities, documents their findings, and reports these findings to DSOD.

<u>La Verne Shops and Construction Equipment</u>: The La Verne Shops were built in the 1940s to support the construction and maintenance of Metropolitan's initial infrastructure. The shops were expanded in the 1960s as Metropolitan's system grew along with its service area. These specialized shops provide support for routine maintenance activities and are also vital for responding to emergency events impacting Metropolitan and member agency facilities. The stockpiling of key materials and the ability to roll pipe and fabricate or repair specialty equipment greatly enhances seismic resilience. Many of Metropolitan's pumps, piping, valves, and related equipment are too large to be routinely stocked by vendors.

Post-1971 San Fernando Earthquake (1971-1990)

The San Fernando earthquake struck the greater Los Angeles region in the early morning of February 9, 1971. The M6.5 earthquake caused severe property damage over $500 million and the loss of life directly attributable to the earthquake reached 58.

There were over 145 post-earthquake ignitions, typically caused by severed gas lines. Metropolitan experienced widespread damage at the Jensen plant, including a severe break to a 72" influent conduit and damage to the new finished water reservoir (shown below).

<u>Earthquake Committee</u>: Following the San Fernando Earthquake in 1971, Metropolitan formed an Earthquake Committee to investigate damaged structures at the Joseph Jensen Water Treatment Plant and to recommend enhanced seismic design criteria and site improvements to mitigate the seismic risk from potential future events.

The recommended modifications, such as the addition of stone columns to prevent liquefaction, are believed to have contributed to improved seismic performance of the Jensen plant in the 1994 Northridge Earthquake (see Section 4 of this report).

The Earthquake Committee also evaluated other facilities and recommended additional improvements that resulted in the upgrade of several key structures throughout Metropolitan's system. The Committee's efforts evolved over time into the current formal approach, with its emphasis on improving the seismic resilience of structures.

<u>Emergency Response Plan:</u> This period also saw Metropolitan adopt its Emergency Response Plan and establish a formal Emergency Response Organization (ERO). These steps led to regular emergency response training for staff, and eventually to staging formal emergency response exercises. As part of this effort, Metropolitan coordinated with its member agencies to establish the Member Agency Response System (MARS). Engineering Damage Assessment Teams (DATs) were also created to rapidly assess damage and help prioritize and initiate repair efforts.

<u>La Verne Shops and Construction Equipment</u>: The La Verne Shops were further expanded in the 1980s to support a major rehabilitation of the main pumps on the Colorado River Aqueduct. The additional fabrication capacity increased Metropolitan's ability to respond to emergency events.

<u>Local Projects Program</u>: To decrease reliance upon imported water, Metropolitan established the Local Projects Program in 1982 to provide financial incentives to member agencies for the development of recycled water projects throughout the region. A more diversified water portfolio helps the region's overall water supply reliability, which improves seismic resilience for the entire service area.

Post-1989 Loma Prieta and 1994 Northridge Earthquake (1990-2010)

During this period, Metropolitan greatly enhanced seismic resilience by performing seismic risk assessments, updating seismic design criteria, strengthening dozens of at-risk structures, encouraging development of local water resources, increasing emergency storage supplies, and enhancing emergency response capabilities.

The M6.9 Loma Prieta earthquake occurred in Northern California on October 17, 1989, at 5:04 p.m. . The shock was centered approximately 10 miles (16 km) northeast of Santa Cruz on a section of the San Andreas Fault System.

The earthquake was responsible for 63 deaths and over 3,750 injuries. The Loma Prieta segment of the San Andreas Fault System had been relatively inactive since the 1906 San Francisco earthquake until two moderate foreshocks occurred in June 1988 and again in August 1989.

As a result of this event, there were more 916 documented water system pipe breaks. This resulted in the loss of water pressure in the Marina District of San Francisco and difficulty in fighting fires.

Seismic Design Criteria: During the Inland Feeder Project, criteria were developed for new pipelines that cross seismic faults. The refined fault-crossing strategy includes using steel pipelines with welded joints; crossing fault-zones at right angles, and burying the pipes at relatively shallow depth to enable easy access for repair; and locating the pipelines where they can drain into channels or streams if damaged at fault crossings. Metropolitan also began considering the benefits of exceeding minimum code requirements for essential structures.

Seismic Upgrade Program: Dozens of pre-1990 structures were upgraded during this period. The benefit of upgrading seismically vulnerable facilities was demonstrated during the Northridge Earthquake in 1994. Structures that were upgraded at the Jensen plant, which was near the earthquake's epicenter, experienced only minor damage. The only significant damage consisted of rupture of an inlet 84-inch steel pipeline. The Jensen plant was off-line for less than 72 hours while the broken pipeline was repaired, and limited water deliveries were maintained during the repairs. Appendix 4 summarizes damage to Metropolitan infrastructure from the 1971 San Fernando and 1994 Northridge earthquakes.

Local Resources Program: In 1995, Metropolitan established the Local Resources Program (LRP). The LRP combined the Local Projects Program, which provided financial incentives for recycled water projects, with the Groundwater Recovery Program, which provided financial incentives to encourage the development of local groundwater recovery projects. The present LRP has been highly successful in reducing the region's dependence upon imported water.

Diamond Valley Lake (DVL): DVL was completed in 1999 to increase operational flexibility and reliability by providing seasonal storage, drought protection, and dedicated emergency supplies. Seismic resilience was a major factor in both the siting and design of the reservoir. DVL was specifically constructed south and west of the San Andreas Fault, and it was designed to withstand a major event on that fault in order to mitigate for the potential interruption of Southern California's imported water supplies. This 810,000 acre-foot reservoir, combined with other storage programs, provides a 6-month emergency water supply for Metropolitan's service area.

The M6.7 Northridge earthquake occurred on January 17, 1994, at 4:31 a.m. and had a duration of approximately 10-20 seconds.

The death toll was 57, with more than 8,700 injured. Property damage was estimated to be between $13 and $50 billion. LADWP reported a total of 1,405 pipe repairs and that water pressure had dropped to zero in some areas.

Metropolitan experienced damage at the Jensen Plant including a rupture of an 84" diameter pipeline. Crews worked around the clock and restored service within 72 hours. The ability to roll pipe in the La Verne shops expedited these emergency repairs.

Although Metropolitan's response was very good, a task force was formed to develop recommendations for further improvement (Ref. Report 1087, "Northridge Earthquake Assessment Report").

Special Seismic Risk Assessments: During this period, Metropolitan broadened the scope of seismic risk assessments, from focusing on isolated structures to assessing entire facilities, such as the Diemer plant, and overall systems, such as the CRA. These efforts included seismic vulnerability assessments, facility reliability assessments, and system flexibility studies. These special seismic risk assessments led to several capital projects to structurally upgrade facilities, provided input into Metropolitan's emergency response planning to reduce the time to restore service, and identified options to improve system flexibility to help maintain water deliveries during planned and unplanned outages.

Emergency Response Planning: Following the Northridge Earthquake, Metropolitan revised its Emergency Response Plan and associated programs and established a Member Agency Coordinator function. Metropolitan also began conducting training exercises in coordination with member agencies and other external agencies and three functional exercises based on postulated seismic events were conducted during this period. In addition, the EOC was relocated from the Sunset Headquarters Building to Eagle Rock, and Incident Command Centers (ICCs) were established at each of the water treatment plants. Recognizing that seismic events can impact business functions as well as infrastructure, staff developed a formal Business Resumption Plan. Over time, this evolved into the present Business Continuity Plan (BCP) and IT Continuity Plan (ITP).

Emergency Response Construction Capabilities: In 2008**,** Metropolitan enhanced its ability to respond to emergency events by initiating a long-term project to refurbish and upgrade the La Verne Shops. Metropolitan can roll pipe and conduct simultaneous repairs on two large-diameter pipelines. Retaining in-house fabrication functions is important, as there are few firms in the western U.S. with similar capabilities. In recent years, private firms with machine shop and fabrication capabilities have tended to increase the amount of work outsourced to offshore facilities, instead of retaining it locally. These firms have little ability to respond expeditiously to emergency needs.

Post-2010 Chile, 2011 Christchurch and 2011 Great East Japan Earthquakes (2010-Present)

<u>Seismic Resilience Strategy Defined:</u> The recent earthquakes in Chile, New Zealand, and Japan demonstrated the importance of seismic resilience, and have resulted in extensive discussions among industry experts and public agencies on strategies to achieve greater levels of seismic resilience beyond the conventional measures of prevention and protection. This was particularly true for the 2011 Christchurch, New Zealand Earthquake, although it was the smallest of the three. The reason was the widespread damage that occurred in the downtown section of Christchurch, despite the fact that the infrastructure was designed and constructed in accordance with modern building codes. While the majority of buildings did not fall, and most people were able to exit safely, many of the downtown structures were unsuitable for occupation and had to be demolished. In addition, many of the buried utilities were damaged and had to be abandoned in place. The combined loss of structures and utilities resulted in a long-term reduction to the population within the city.

A M6.3 earthquake occurred in Christchurch, New Zealand on 22 February 2011 at 12:51 p.m. The earthquake was centered 6 miles south-east of the center of Christchurch, which at the time was New Zealand's second-most populous city. The earthquake caused widespread damage across Christchurch, killing 185 people in the nation's fifth-deadliest disaster.

In December 2014, Los Angeles Mayor Eric Garcetti released Resilience by Design which provided recommendations to addresses Los Angeles' greatest earthquake vulnerabilities, including taking steps to secure imported water supplies.

Concurrent with the infrastructure industry's focus on resilience, Metropolitan re-assessed its existing programs and developed a more integrated, comprehensive approach to seismic resilience. One improvement was to incorporate the concept of performance-based design during seismic evaluations. In addition to the evaluation of structures based on design-level earthquakes to prevent damage, performance-based design evaluates the effects of more extreme events to anticipate structural damage. Another improvement was to embrace the significant technological advancements that can improve seismic resilience, including computer modeling techniques, seismic resistant products, and recent industry research. These improvements have allowed Metropolitan to develop an enhanced strategy for seismic resilience moving forward.

During this period, Metropolitan also formed a collaborative Task Force to address the unique vulnerabilities of the major aqueducts that cross the San Andreas Fault. In 2017, Metropolitan fully integrated the various seismic resilience efforts currently underway throughout the organization. The resulting Seismic Resilience Strategy is described in detail in Sections 3 through 7 of this report.

Metropolitan's Comprehensive, Integrated Seismic Resilience Strategy

The enhanced Seismic Resilience Strategy has the following objectives for Metropolitan and for the entire southern California region:

- Provide a diversified water supply portfolio, system flexibility, and emergency storage
- Prevent damage to water delivery infrastructure in probable seismic events and limit damage in extreme events
- Minimize water delivery interruptions through a dedicated emergency response and recovery organization

This strategy is built upon improved collaboration within Metropolitan and formal collaboration with LADWP and DWR, which also import water to Southern California.

Figure 2-4: Detailed Breakdown of Metropolitan's Seismic Resilience Strategy

As shown in **Figure 2-4**, Metropolitan's enhanced Seismic Resilience Strategy includes four components within Metropolitan and a fifth component that involves formal coordination between Metropolitan, LADWP, and DWR.

1. The **<u>Planning component</u>** develops diversified water resources, system flexibility, and emergency water storage through Metropolitan's Integrated Water Resources Plan (IRP) and System Overview Studies. The goal of Metropolitan's IRP is to develop a diverse water supply portfolio that will be able to maintain a reliable water supply under any conditions, including a major seismic event.
2. The **<u>Engineering component</u>** addresses design concepts, vulnerability studies, and seismic resilience projects executed under Metropolitan's Capital Investment Plan (CIP). The Engineering component includes evaluating the seismic resilience of structures, monitoring dams, special seismic assessments, and enhancing pipeline seismic resilience. These efforts are all aimed at improving the seismic resilience of the treatment plants and distribution system through facility upgrades and operational flexibility improvements.
3. The **<u>Operations component</u>** involves Metropolitan's emergency response organization, training exercises, and construction capabilities. Their objectives are to effectively prepare for and respond to emergency events so that impacts to water deliveries are minimized and interrupted deliveries are restored quickly.
4. The **<u>Reporting component</u>** involves documenting the Seismic Resilience Strategy, tracking progress of seismic resilience activities, and annual reporting of near-term goals and recent accomplishments to Metropolitan's Board. This component is aimed at facilitating knowledge transfer, increasing accountability, and improving the transparency of seismic resilience goals and achievements to the Board and member agencies. The reporting component also supports the planning efforts of member agencies by communicating potential outage durations of Metropolitan facilities during emergency events.
5. The **<u>Seismic Resilience Water Supply Task Force component</u>** involves Metropolitan's formal collaboration with DWR, LADWP, the State of California, and other water industry organizations to address the unique seismic vulnerabilities of Southern California's imported water supplies. The two primary objectives of this task force are to 1) enable the agencies to coordinate emergency response efforts, and 2) identify practical mitigation options for reducing the magnitude and duration of disruptions to the region's imported water supplies following a large earthquake on the San Andreas Fault.

SECTION 3 PLANNING COMPONENT

As a supplemental supplier to the Southern California water community, Metropolitan faces many challenges in meeting the region's needs for water supply reliability and quality. One of the challenges is the ability to maintain water deliveries within the region following a major seismic event. In general, Metropolitan's planning efforts focus on meeting demands during dry and critical periods. However, during the original planning for Diamond Valley Lake (DVL), Metropolitan considered a scenario and a plan to meet demands if imported supplies were interrupted due to a seismic event, including development of a significant increase in storage dedicated to meeting emergencies.

Historically, Metropolitan has provided 50 to 60 percent of the water used in its service area from the Colorado River (via the Colorado River Aqueduct) and from the Sacramento-San Joaquin River Watershed (via the State Water Project). In addition to relying on imported supplies, Metropolitan and its member agencies have developed other sources, including groundwater, surface water, recycled water, desalination of seawater, and an aggressive water conservation and water use efficiency program. These investments, and Metropolitan's ongoing efforts in several different areas, coalesce toward the goal of long-term regional water supply reliability.

Metropolitan's Integrated Water Resources Plan (IRP) is the foundation for planning and developing a diverse water supply and emergency storage. The fundamental goal of the IRP is for Southern California to develop a water supply portfolio that will be able to maintain a reliable water supply. Maintaining this reliability includes investments prior to major seismic events, when there could be extended outages of imported water conveyance systems. To meet this fundamental IRP goal of a diversified water portfolio, Metropolitan believes in investing in the reliability of imported supplies, incentivizing its member agencies to develop increased water conservation, recycling, storage, and other resource-management programs. A significant part of imported water supply reliability is preparing for recovery periods following seismic events. With the commencement of the IRP process in 1993, Metropolitan formalized this process as a long-term strategy and official policy.

Metropolitan's success in improving water supply reliability by diversifying its water resource portfolio, and by the application of adaptive resource management approaches has also increased seismic resilience. At a system level, the Planning component of seismic resilience has several facets:

- Diversified water supply portfolio
- System flexibility
- Emergency storage

Diversified Water Supply Portfolio

Metropolitan has undertaken a number of planning initiatives over the years in order to maintain a diversified water portfolio. These initiatives include the IRP, periodic IRP updates, the Water Surplus and Drought Management (WSDM) Plan, and the Water Supply Allocation Plan (WSAP). Collectively, these initiatives provide policy framework guidelines and resource targets for Metropolitan to ensure regional water supply reliability, along with additional resilience for seismic events. In addition to Metropolitan's efforts to coordinate regional supply planning through its inclusive IRP process, Metropolitan's member agencies also conduct their own planning analyses and may develop projects independently of Metropolitan.

2015 IRP Update

The 2015 IRP Update was a refinement of Southern California's water management strategy, with seismic resilience continuing to be a key component. The 2015 IRP Update called for increasing the targets for conservation and local supply development and an emphasis on the importance of protecting and maintaining existing local supplies. The more that conservation and local supplies can contribute to the baseline each year, the more imported water Metropolitan can divert into storage to prepare for droughts of unknown duration or potential seismic events. Further developing a diverse water supply portfolio also contributes to increased seismic resilience.

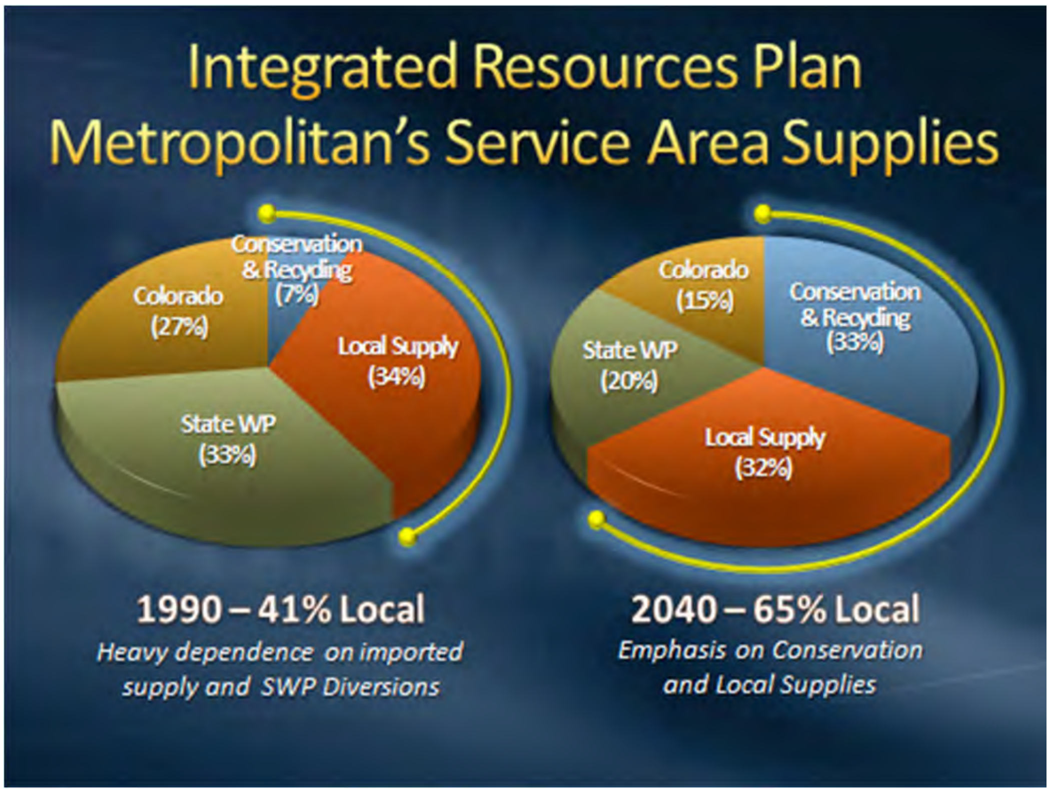

Figure 3-1: Integrated Resource Plan, Metropolitan's Service Area Supplies

Metropolitan's Service Area Supplies under the IRP

In 1990, about 41 percent of regional water demands were met with local resources and conservation. By 2040, about two-thirds will be met by local resources and increased conservation and recycling, as shown in **Figure 3-1**. Metropolitan's strategy is to maintain rather than increase traditional levels of imported supplies. The long-term portfolio approach looks to local solutions to sustain the region's continued growth. Increased flexibility to draw upon a wide range of sources from an ever more diverse water supply portfolio results in greater resilience to the potential impacts of seismic events on Southern California's water supply infrastructure.

Water Surplus and Drought Management (WSDM) Plan

Diversifying the region's water supplies and developing adequate and healthy water storage reserves have proven to be the backstop for water supply reliability. These actions have also contributed to improved seismic resilience for the region. Stored water reserves provide certainty for meeting the needs of the region's vast service area when traditional sources of supply are challenged by drought, climate change, seismic events, and other risks. It is critical that these storage resources be developed, managed and enhanced.

Metropolitan's WSDM Plan, which defines a regional water management strategy for Metropolitan and its member agencies, has focused on using storage to manage water supplies and enhance reliability since 1999. The WSDM Plan includes the following guiding principle: Metropolitan will encourage storage of water during periods of surplus and work jointly with its member agencies to minimize the impacts of water shortages on the region's retail consumers and economy during periods of shortage.

Water Supply Allocation Plan

When continued drought, earthquakes, or other natural disasters lead to shortages of supplies, Metropolitan distributes a limited amount of water through its Water Supply Allocation Plan (WSAP). First developed in 2008, Metropolitan's WSAP takes a basic premise --to fairly distribute a limited amount of water supply-- and applies it through a detailed methodology to reflect a range of local conditions and needs of the region's retail water consumers. In particular, under severe drought conditions or a potential seismic event that impacts imported conveyance systems, it may be necessary and prudent to call for greater reductions in the use of limited water supplies and to reduce reliance on storage reserves. The WSAP has 10 levels of water supply allocations, each corresponding to a five percent reduction of supply. A Level 2 allocation, for example, represents a reduction of approximately 10 percent in overall water supply available to each member agency. The level of WSAP reduction implemented would correlate to the severity of the seismic event.

System Flexibility

Metropolitan develops its facilities to meet demands; however, in the course of developing a reliable system to meet demands, some flexibility has been incorporated into the system. This flexibility helps Metropolitan accommodate changes in water supply, demands, and water quality. System flexibility also helps mitigate the impacts of planned and unplanned outages. Metropolitan's system flexibility has two key components:

- Operational flexibility: the ability to respond to changes in regional supply, water quality, or member agency demands
- Delivery flexibility: the ability to maintain partial to full deliveries during planned and unplanned single-facility outages

Metropolitan has found that for planned and unplanned outages of Metropolitan facilities, system flexibility at the regional and local levels is key to minimizing the effects of these outages. Water supply reliability and water demand-driven projects increase Metropolitan's system flexibility, which in turn can also increase seismic resilience. For example, the construction of DVL and the Inland Feeder provided significantly increased water supply reliability through the potential for dramatically increased storage of imported supplies within the service area. These projects increased water supply reliability and system flexibility, and also greatly improved seismic resilience as the storage was purposely located on the coastal side of major faults that are crossed by the SWP, CRA, and Los Angeles Aqueduct (LAA). A significant amount of storage in DVL is dedicated to emergency storage. This water is not used except in emergency conditions such as following a major seismic event. Additionally, the Diemer and Jensen plants (and associated feeders) were constructed as water demand-driven projects that also significantly improved delivery flexibility and seismic resilience within Metropolitan's distribution system.

Emergency Storage

Over the past two decades, Metropolitan has developed a large regional storage portfolio that includes both dry year and emergency storage capacity (summarized in Appendix 5). Storage generally takes two forms: surface reservoirs and groundwater basin storage. In late 2011, heading into the most recent drought cycle, Metropolitan had developed over 5.5 million acre-feet of storage capacity and had successfully stored over 2.7 million acre-feet.

Additionally, Metropolitan has long discussed and executed plans to maintain a reliable supply of water in the face of any type of water supply condition, including following major seismic events that could impact imported water conveyance systems. The development of its diverse resource mix has enhanced the flexibility of Metropolitan's conveyance and distribution system. Metropolitan established criteria for determining emergency storage requirements in the October 1991 Final Environmental Impact Report for the Eastside Reservoir, which is now DVL. These criteria were again discussed in the 1996 IRP. Both of these documents were approved by Metropolitan's Board. Additionally, Metropolitan's emergency storage requirements were summarized in a 2008 Board Report entitled "Water Surplus and Drought Management Plan on water supply and demand as of October 30, 2008."

Emergency storage requirements are based on the potential of a major earthquake causing damage to one or more of the aqueducts that convey Southern California's imported supplies (SWP, CRA, and LAA) into the region. The adopted criteria assume that damage from such an event could render the aqueducts out of service for six months. As a result, Metropolitan has based its planning on a 100 percent reduction in these imported supplies for a period of six months.

Metropolitan's WSDM Plan shortage stages guide Metropolitan's management of available supplies and resources during an emergency to minimize impacts of the catastrophe. This emergency plan outlines that under catastrophic loss of water supply the following actions will be taken:

1. Interruptible water deliveries would be suspended
2. Firm supplies to member agencies would be restricted by a mandatory cutback of 25 percent from normal year retail demand levels
3. Water stored in surface reservoirs and groundwater basins under Metropolitan's program would be made available

4. Full local groundwater production, recycled water, and local surface emergency storage reserve production would be sustained
5. Metropolitan would draw on its emergency storage as well as other available storage

Under the emergency criteria, retail demands would be met through existing surface storage, local production, and storage in surface reservoirs owned and operated by Metropolitan and by DWR. The total amount of storage available for emergency needs in Metropolitan's storage facilities, including DVL, Lake Mathews, and Lake Skinner, is currently 292,100 acre-feet (February 2018). The amount of emergency storage available to Metropolitan in DWR's reservoirs, including Lake Perris, Castaic Lake, Silverwood Lake, and Pyramid Lake, is an additional 334,300 acre-feet (February 2018).

SUMMARY

Through its IRP, Metropolitan has established a fundamental goal that Southern California will have a reliable water supply system for present and future generations, even if imported water supplies are disrupted due to a major seismic event. This reliability is achieved through Metropolitan's development of local water supplies, emphasis on water conservation, and establishment of emergency storage on the coastal side of major earthquake faults that are crossed by the SWP, CRA, and LAA. These reliability actions enable Southern California to continue water deliveries during the period when imported supply aqueducts are out of service due to damage from a major seismic event. In addition, Metropolitan's planning efforts to diversify the water supply and increase overall system flexibility over time have also contributed to providing resilience against potential in-basin earthquakes.

Metropolitan will continue to evaluate its water resource planning programs in terms of how they may further enhance seismic resilience and coordinate these efforts with the Engineering and Operations functions that are described in Sections 4 and 5 of this report.

SECTION 4 ENGINEERING COMPONENT

Metropolitan manages a number of strategies and component studies that evaluate facilities and systems against earthquake hazards. Mitigation options are then developed and executed when practical. These strategies include evaluating the seismic resilience of structures; special seismic assessments that address multiple facilities and systems; and other specialized efforts that address the seismic resilience of dams and reservoirs and the mitigation of geotechnical hazards.

Seismic Resilience of Structures

The purpose of evaluating the seismic resilience of structures is to prevent seismic damage to water delivery infrastructure from probable events and to limit damage due to extreme events in order to minimize water delivery interruptions. For occupied structures, the goal is to protect life safety and critical functions. Metropolitan applies a systematic approach to evaluate older structures that were constructed in accordance with earlier codes, and where necessary, to upgrade structures with seismic deficiencies. The criteria applied to the seismic evaluations incorporate current code provisions and up-to-date industry standards. In general, structures are upgraded to maintain seismic performance levels that are comparable to the levels of a new facility. Additional details are provided in Appendix 6, "Seismic Design Frequently Asked Questions."

Over the past two decades, this effort was primarily aimed at improving the seismic resilience of above-ground facilities and structures constructed prior to 1990. For example, the original pump houses at the five CRA pumping plants were determined to be vulnerable to significant damage in a design-level earthquake. A design-level earthquake is a probable event that is defined by the Building Code as the basis for seismic design of structures. To address this vulnerability, which could have impacted deliveries from the CRA over an extended period, new buttress walls were constructed in 1996.

Construction of new buttress walls at Hinds Pumping Plant

Procedure for Seismic Evaluation of Structures

A seismic risk-reduction program identifies seismic deficiencies of structures and quantifies the associated risks through an effective evaluation process, enabling limited resources to be allocated strategically to projects that address key vulnerabilities and to maximize improvements in seismic resilience of the water delivery system.

Metropolitan's procedure for the seismic evaluation of structures includes the following steps:

1. **Preliminary evaluation of all high-risk structures**

   The preliminary evaluation of existing structures is a high-level assessment to quickly determine if a structure is seismically deficient. Typically, this evaluation involves drawing review, visual inspection, and simplified calculations. If a potential seismic deficiency is identified, the structure is categorized as seismically deficient and the preliminary evaluation is complete.

2. **Prioritization of structures with seismic deficiencies**

   Structures identified as seismically deficient are then prioritized in preparation for a detailed evaluation. Structures built after 1990 were designed and constructed in accordance with the 1988 or later versions of the Uniform Building Code (UBC), which provides reasonable assurance of withstanding a design-level earthquake without catastrophic structural failure. Therefore, structures built before the early 1990's are given priority for the detailed evaluations, with consideration of life safety and the importance of the facility in water deliveries.

3. **Detailed evaluation to develop retrofit options**

   Structures identified with at least one potential seismic deficiency via the preliminary evaluation are thoroughly assessed to confirm any deficiencies. Feasible retrofit options are developed during this step to mitigate the identified deficiencies, and more advanced procedures such as finite element modeling and comprehensive structural calculations may also be applied. The analysis methodology, its results, findings, and recommendations are then summarized in a report that includes rough order-of-magnitude construction costs.

4. **Final retrofit design to strengthen deficient structures**

   The recommendations from the detailed evaluation form the basis for requesting approval from the Board of Directors to proceed with a seismic upgrade project. A project team consisting of design engineers and a project manager considers all feasible retrofit options developed during the detailed evaluation and recommends one option for the final retrofit design. In this process, the project team considers adequacy for seismic resistance, cost, constructability, operational impacts, and environmental impacts to select the preferred option. The selected option is then developed into bidding documents that include detailed design drawings and specifications for the retrofit work.

5. **Periodic reevaluation of strengthened structures**

   The seismic design provisions in building codes are constantly evolving, which reflects lessons learned from recent earthquakes and new findings in regional seismicity. Metropolitan periodically re-evaluates its facilities to ensure that system reliability is not compromised due to newly discovered vulnerabilities. Factors that may trigger a re-evaluation of a previously upgraded structure include:

   - Substantial increase of seismic hazard level at the site
   - New discovery of site seismicity
   - New discovery of potential seismic deficiencies in the structure
   - Significant deterioration of existing materials in the structure

Progress to date

A comprehensive inventory list of Metropolitan's above-ground structures is used to track the progress of the evaluation and seismic upgrades of structures. To date, Metropolitan has completed preliminary evaluations of all 311 pre-1990 above-ground structures (see **Figure 4-1**). Upgrades of many critical structures have also been completed, including the five pumping plants along the Colorado River Aqueduct, the Jensen Administration Building, and the Lake Mathews Outlet Tower.

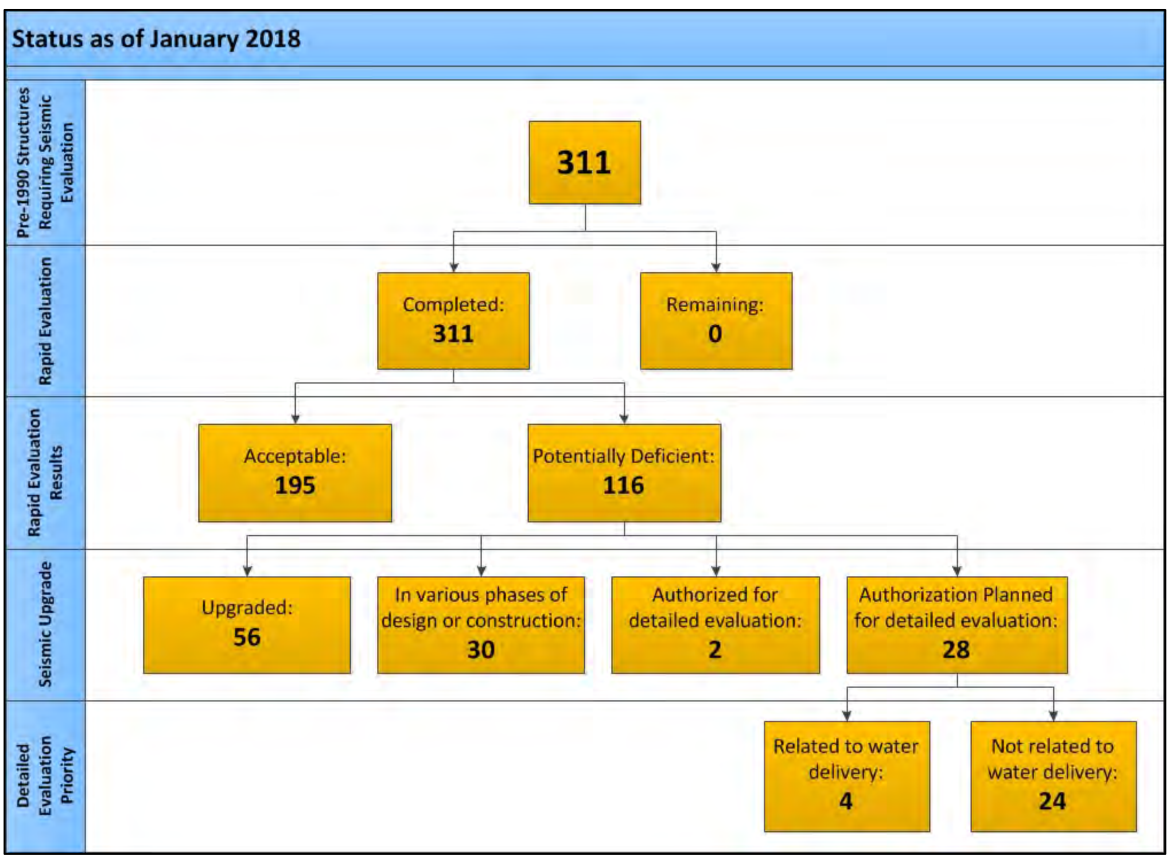

Figure 4-1: Status of Seismic Assessments and Upgrades of Pre-1990 Structures

As shown in the figure, of the 116 structures identified as potentially deficient, 56 have been upgraded and 32 are authorized for study, design or construction. The remaining 28 structures will proceed through Metropolitan's CIP evaluation process to obtain authorization for the detailed evaluations. Since 1998, Metropolitan has invested over $200M in seismic upgrades of its key structures.

Expanded Approach for Achieving Seismic Resilience of Structures

In 2017, the strategy for achieving the seismic resilience of structures was modified to further enhance the seismic resilience of the delivery system. The refined strategy moved beyond assessing only Pre-1990 above-ground structures to include the following:

- Fully and partially buried structures
- Seismic anchorage and bracing of non-structural components such as equipment, pipes, and ducts.
- Structures constructed between 1990 and 2000 (prior to the adoption of UBC1997)

For the first two items, it was recognized that fully and partially buried structures, while less vulnerable to seismic hazards than above-ground structures, are nevertheless important to maintaining system reliability. Similarly, the seismic resilience of non-structural components, such as equipment and piping, is also important for minimizing operational downtime after an earthquake.

The third item, relating to UBC1997, is included in the expanded effort since seismic design codes have been modified such that some structures designed and constructed after 1990 also warrant an assessment. Recorded ground motions in the 1994 Northridge Earthquake, for example, revealed that the design seismic force specified in building codes at the time were underestimated for sites located close to faults. This near-fault effect was incorporated into the subsequent code (UBC 1997). As a result, certain structures designed between 1990-2000 prior to the adoption of UBC 1997 may be vulnerable to a major earthquake.

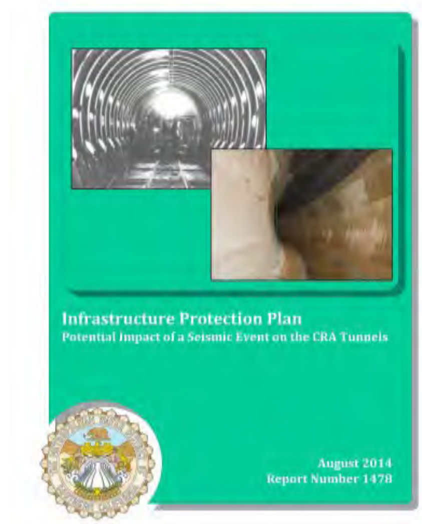
Moving forward, the near-term focus is to complete the detailed evaluations and seismic retrofit projects that have been authorized to date. Long-term goals include:

- Continue assessment of seismic design criteria to incorporate updated seismic resilience strategy
- Document a systematic approach to improve seismic resilience of non-structural components
- Conduct preliminary evaluations for critical fully or partially buried structures
- Conduct preliminary evaluation of post-1990 structures.

Special Seismic Assessments

Special seismic assessments are performed to complement the original seismic resilience of structures evaluations. These special assessments include seismic vulnerability evaluations, general reliability assessments, and system flexibility studies.

Seismic Vulnerability Evaluations. Seismic vulnerability evaluations identify potential impacts of credible earthquake scenarios on individual facilities and the system as a whole. For these studies, staff review current and readily available seismic hazard data from public, academic, state, and federal sources, as well as input from geotechnical consultants, to screen each facility or system (e.g., the CRA) for its level of exposure to seismic hazards (i.e., surface displacement, ground shaking, liquefaction, and landslides) during a major seismic event. Based on the potential level of exposure and the resulting damage to Metropolitan facilities, the time to restore service are estimated. These studies then evaluate the impact of the damage on Metropolitan's water delivery capability and identify areas with limited backup capability to provide water while the facility is out of service. Improvements that could reduce the loss of service, and/or reduce the time to restore service, are then identified and prioritized.



The 2014 Potential Impact of a Seismic Event on the CRA Tunnels validated historic assumptions regarding potential outage durations for the CRA tunnels.

Findings from these evaluations can lead to capital improvements to strengthen facilities, improve system flexibility, and/or provide input into Metropolitan's emergency response planning to improve the seismic resilience of the distribution system.

To date, Metropolitan has completed over ten seismic vulnerability studies. A few examples are listed below, while a complete list with a brief summary of each study is included in Appendix 7.

- *Seismic Risk Assessment of Local Water Production Facilities in the Service Area of Metropolitan Water District of Southern California,* January 14, 1991, Dames & Moore
- *Probable Maximum Loss Analysis for Metropolitan Water District of Southern California*, September 1998, EQE International
- 2009 Report No. 1335: *Effects of Southern California Seismic Events on Metropolitan Water District Deliveries*
- 2014 Report No. 1490: *Colorado River Aqueduct Seismic Vulnerability Investigations – Summary Report*
- 2017 Report No. 1533: *Seismic Risk Assessment – Conveyance and Distribution System Tunnels*

General Reliability Assessments. The vulnerability of Metropolitan's facilities to damage from major seismic events is also evaluated through general reliability assessments. The objective of these assessments is to examine the vulnerability of facilities to unplanned service interruptions from the following hazards and events:

Seismic activity	Fire
Hydraulic surge	Corrosion
Vehicle impact	Wind-blown projectiles
Equipment malfunction	Third-party construction
Erosion/Scour/Flooding	Vandalism

The assessments are based on compiling data collected from several sources and evaluating the information to identify vulnerabilities that may damage a facility and impact water deliveries. The sources of information include prior reliability studies conducted for the facility; the facility's piping and instrumentation diagrams, electrical single-line drawings and plant layout drawings; interviews with Water System Operations and Engineering Services staff; reviews of corrective maintenance reports, reviews of CIP projects; and field inspections of the facilities.

The general reliability assessments focus on the following when relating to seismic activities:

- Assessing the ability of individual equipment and piping within the facilities to withstand an earthquake
- Reviewing potential soil stability issues that might affect earthquake vulnerability with Metropolitan's geotechnical staff
- Reviewing the ability of existing critical structures (i.e., tanks, treatment basins and pump house buildings) to withstand a seismic event

After identifying potential vulnerabilities to specific hazards and events, staff categorize the vulnerabilities based on the potential service impacts and identify options to mitigate the vulnerability and improve reliability. Mitigation steps include conducting capital projects to rehabilitate, replace, or upgrade equipment and facilities; performing operation and maintenance (O&M) activities for minor equipment modifications; creating procedures for designing, operating or maintaining the facility; and refining Metropolitan's emergency response plan. These options are prioritized based on their potential impact on the operation of the facility and are considered for evaluation and action. The cost and benefit of options that involve capital projects are evaluated through the normal CIP evaluation process.

Metropolitan has completed a total of eight general reliability assessments to date, including assessments of the CRA, all five water treatment plants, the conveyance system, and portions of the distribution system. A few examples are listed below, while a complete list with a brief summary of each study is presented in Appendix 7. As the understanding of earthquake probability and seismic forces continues to increase, these studies will be periodically updated.

- 2006 Report No. 1227: *Distribution System Reliability Assessment*
- 2006 Report No. 1255: *Weymouth Water Treatment Plant Reliability Assessment*
- 2006 Report No. 1297: *Colorado River Aqueduct Reliability Assessment*

System Flexibility Studies. System flexibility studies identify:

1. The impacts of regional facility outages on water deliveries to member agencies
2. Areas with limited flexibility to serve water, which may impact deliveries during an outage
3. Options to improve system flexibility (e.g., interconnections with other agencies, local resource development, or isolation valves).

These studies postulate outages to Metropolitan and DWR facilities, assign a reasonable duration to the outage based on past experience, and then evaluate the impact of the assumed outage on water deliveries through the following steps:

1. Identify service connections affected by an outage
2. Evaluate Metropolitan options to deliver water to the affected service connections

3. Evaluate member agency backup options (e.g., wells, treatment plants, surface storage, interconnections with other agencies) to deliver water to affected service connections
4. Quantify the impact of each outage in terms of loss of retail service to affected service connections, and identify service connections and/or regions with limited or no backup capability
5. Identify options to mitigate the impact of the outage and improve system flexibility to respond to planned and unplanned outages

The results of these studies support member agencies' efforts to improve local system reliability in the event of a planned or unplanned outage of a Metropolitan facility; support joint efforts of Metropolitan and its member agencies in evaluating the reliability benefits of potential projects; and support Metropolitan's efforts to identify options to improve operational flexibility.

Two significant system flexibility studies have been completed to date:

- **System Reliability Study (2006).** This study evaluated the flexibility of Metropolitan's overall distribution system. The study examined the impact of single failures in the system to the ability to deliver water to member agencies and identified existing backup options to deliver water during the outage. Specific types of failures considered in the study included individual facility failures (e.g., the CRA, a treatment plant, a reservoir) and failures in each isolatable segment of the distribution system (e.g., pipelines). Over 250 different postulated events were considered, and the impact on delivery to each service connection was evaluated for each event. The study considered the capabilities both within Metropolitan's system as well as the member agencies' to mitigate impacts of an outage. The study did not, however, consider multiple failures that might be associated with an earthquake, due to the almost unlimited number of combinations of failures that would have to be considered. Metropolitan and member agency discussions regarding this study and local and regional obligations led to a clarification about Administrative Code 4503 "Suspension of Deliveries" that is included in Appendix 8.
- **Mills Water Supply Reliability Study (Report No. 1337).** One of the findings of the 2007 Integrated Area Study was that the supply of raw water to the Mills plant had a lesser degree of redundancy than Metropolitan's other water treatment plants. The Mills Water Supply Reliability Study was undertaken to evaluate conditions that could interrupt the normal raw water supply to the Mills plant, such as earthquakes, and develop options to improve the redundancy and flexibility of supply to the plant.

Seismic Resilience of Dams and Reservoirs

The seismic stability of Metropolitan's dams is safeguarded by a robust and proactive comprehensive dam safety strategy managed by the Safety of Dams Team. The core responsibilities of the Safety of Dams Team are to perform inspections, interpret and analyze collected surveillance and monitoring data, evaluate dam structures and appurtenant works, report the findings, and serve as Metropolitan's liaison with the California Department of Water Resources, Division of Safety of Dams (DSOD).

Metropolitan owns and operates 20 facilities that are under the jurisdiction of DSOD, as listed in Table 4-1. There are a total of 24 individual dams/reservoirs, as some of these facilities have multiple dams.

Table 4-1: Current Metropolitan Jurisdictional Dam and Reservoir Facilities

Dam/Reservoir Name	Dam Type
Cajalco Creek Detention Basin	Flood Control
Copper Basin Reservoir	Surface Water Reservoir
Diamond Valley Forebay	Hydraulic Structure
Diamond Valley Lake	Surface Water Reservoir
Diemer Mixing & Settling Basin No. 8	Hydraulic Structure
Diemer Ozone Contactor Basins	Hydraulic Structure
Diemer Treated Water Reservoir	Hydraulic Structure
Garvey Reservoir	Surface Water Reservoir
Gene Wash Reservoir	Surface Water Reservoir
Goodhart Canyon Detention Basin	Flood Control
Lake Mathews	Surface Water Reservoir
Lake Skinner	Surface Water Reservoir
Live Oak Reservoir	Surface Water Reservoir
Mills Reclamation Basin No. 14	Hydraulic Structure
Mills Treated Water Reservoir No. 1	Hydraulic Structure
Mills Treated Water Reservoir No. 2	Hydraulic Structure
Orange County Reservoir	Surface Water Reservoir
Palos Verdes Reservoir	Surface Water Reservoir
Skinner Treated Water Reservoir	Hydraulic Structure
Weymouth Treated Water Reservoir	Hydraulic Structure

Metropolitan's Comprehensive Dam Safety Management Program

Metropolitan's comprehensive dam safety strategy is comprised of six key elements:

1. Regular detailed inspections
2. Surveillance monitoring and performance reporting
3. Cyclical facility assessments
4. Emergency preparedness
5. Inundation map preparation
6. Execution of capital projects

Regular Detailed Inspections

Regular detailed inspections are essential to preserve the integrity of a dam and are necessary for early problem detection and remediation. All Metropolitan dams are regularly inspected by Metropolitan staff at specific intervals using a formal, multilayered process:

- Daily or weekly observations
- Monthly inspections of dam and reservoir facilities with the highest DSOD designated hazard classification, with at least semi-annual inspections of all other facilities
- Detailed mandatory annual inspections conducted in the presence of DSOD staff

Upon completion of the annual DSOD inspections, DSOD prepares and provides a summary inspection report that summarizes their findings and may identify recommended remedial work, which is cataloged as action items that are corrected promptly.

Surveillance Monitoring and Performance Reporting

All Metropolitan dams and reservoirs incorporate instrumentation that measures specific performance parameters such as dam or structural movement, water levels, and seepage, as well as other parameters such as shaking due to earthquakes. Collected data are retained as part of the required annual DSOD inspection report.

In terms of seismic resilience, data from surveillance monitoring and performance reporting contribute to the Cyclic Facility Assessments described below by identifying changes in specific parameters, such as dam or reservoir movement or increased seepage, that may indicate a condition that could affect the ability of the dam or reservoir to withstand an earthquake.

Cyclical Facility Assessments

Cyclic facility assessments were initiated at Metropolitan in 2004 and are generally repeated about every 10 years. These assessments use the most up-to-date data and evaluation criteria to identify potential vulnerabilities in dam embankments, dam structures, foundations, outlet facilities and spillways and develop mitigation options, if necessary. If a potential vulnerability or deficiency is identified, a rehabilitation or remediation project may be included in Metropolitan's CIP.

An example of a facility assessment that evolved into a project under Metropolitan's CIP is the Lake Mathews Outlet Tower. The outlet tower, which is critical for water deliveries to a large portion of Metropolitan's service area, was constructed in 1938 and modified in 1961 to increase its height by 30 feet. A facility assessment conducted in 1994 determined that the modified tower was vulnerable to significant damage from ground shaking. A project was authorized to evaluate and address this vulnerability, resulting in a new seismically resilient Outlet Tower being constructed in 2005.

New and Old Outlet Towers at Lake Mathews (2008)

Emergency Preparedness

Metropolitan has a comprehensive Emergency Action Plan (EAP) for each of its dam and reservoir facilities. The EAP identifies potential emergency conditions that could occur at a dam or reservoir facility and describes procedures to be implemented to minimize loss of life and property damage. EAPs serve to provide guidance to responders, local agencies, and stakeholders in evaluating potential hazards, determining the severity of the emergency, and establishing communication protocols. Required content of dam EAPs are provided in the Federal Emergency Management Agency's (FEMA) Federal Guidelines for Dam Safety, Emergency Action Planning for Dams (FEMA 64, July 2013).

Inundation Map Preparation

Inundation maps illustrate worst-case flooding that would result in the complete draining of a full reservoir. Inundation maps show lateral and longitudinal extent of flooding, flood wave arrival times, maximum flood wave depths, total flooding duration, and peak flood flow rates. Inundation maps are a required component of dam and reservoir EAPs and are used by local emergency response agencies for emergency planning purposes.

Metropolitan's current cycle of inundation mapping updates is planned to be completed by 2018 for all dam and reservoir facilities.

Execution of Capital Projects

Dam and reservoir facility vulnerabilities or deficiencies that are identified during detailed inspections or from cyclical assessments are proposed for rehabilitation or remediation through Metropolitan's CIP. Past examples of facility rehabilitation or remediation projects include the Lake Mathews Outlet Facilities, described earlier, and the Seismic Upgrade of the Diemer Finished Water Reservoir.

Currently, several dam and reservoir related capital projects are in progress, including the final design of the outlet valve replacements at Copper Basin and Gene Wash Reservoirs and the construction of the Palos Verdes Reservoir floating cover replacement and tower seismic upgrades. Planned future projects include floating cover replacements and facility upgrades for the Mills Finished Water Reservoir Nos. 1 and 2 and Garvey Reservoir.

Pipeline Seismic Resilience

Metropolitan's pipelines are exposed to a number of geohazards of varying risk, including fault zone crossings, permanent ground deformation from causes such as liquefaction or landslides, and ground shaking during seismic events. While Metropolitan's pipelines have always been constructed in conformance with standards of practice at the time of design, there haven't been code requirements to address seismic risk. In addition, until recently, there have not been mitigation options for large diameter pipelines.

The photograph on the left shows a pipe joint pullout due to liquefaction from 1995 in Kobe, Japan. (photo courtesy of D. Ballantyne, *Understanding the Seismic Vulnerability of Water Systems*, Regional Water Providers Consortium Board, October 2013)

The photograph on the right shows pipe damage at a fault crossing (photo courtesy of D. Ballantyne, *Understanding the Seismic Vulnerability of Water Systems*, Regional Water Providers Consortium Board, October 2013)

There are currently several seismic resistant pipeline options, such as earthquake resistant ductile iron pipelines with special seismic resistant joints (see **Figure 4-2**), that are becoming available in diameters suitable for use by Metropolitan.

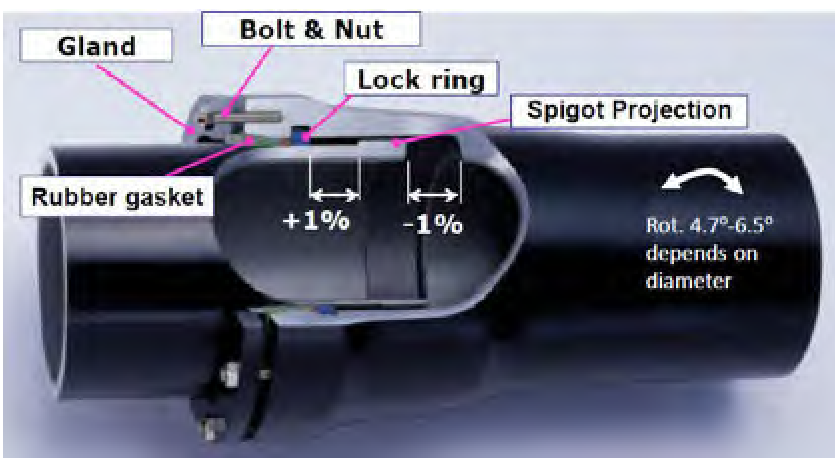


Figure 4-2: Example of Seismic Resistant Pipe (courtesy of Kubota Corp. and JFE)

As mentioned previously, Metropolitan is now formalizing a strategy to achieve significant improvements in seismic resistance of the distribution system over time. This approach takes advantage of up-to-date seismicity data, modern computer modeling techniques, recently developed seismic resistant products, extensive industry research, and updated codes.

The seismic resilience strategy for pipelines has three components:

1. Part 1 – Conducting vulnerability assessments of the existing distribution system
2. Part 2 – Identifying potential mitigation measures for existing pipelines
3. Part 3 – Establishing design and performance criteria for new pipelines and rehabilitation projects

Parts 1 and 2 are described below in more detail. Part 3 for new pipelines will be developed in conjunction with several new large-diameter pipeline projects that are planned over the next 5 to 10 years.

Part 1 –Vulnerability Assessment of Existing Pipelines: Due to the relatively good performance of large-diameter pipelines within Metropolitan's distribution system during previous earthquakes, Metropolitan is focusing on the most vulnerable existing pipelines to establish the need and priority of future mitigation work as well as integrating seismic mitigation into planned rehabilitation programs for aging pipelines. This approach is currently being followed for the PCCP Rehabilitation Program. It is anticipated that there will be relatively few cases where it would be considered cost-effective to upgrade a pipeline solely to enhance seismic resilience.

Vulnerability assessments of pipelines within the distribution system follow the same multi-step approach used for traditional risk assessments. The initial steps entail gathering available geologic, seismologic, and geodetic data, and then identifying seismic hazards along a pipeline route, such as fault zone crossings, liquefaction zones, and landslide hazards. Three simulated earthquake scenarios are considered in the evaluation: a frequent seismic event, moderate event, and a severe event. The hazard assessment provides a bounded solution that includes the expected probable and maximum probable damage for each earthquake scenario.

The resulting damage to the pipeline due to the three design seismic scenarios provides an insight into the corresponding consequences of disruption. These consequences include life-safety impacts, delivery impacts, and societal/environmental impacts.

Preliminary screening is then performed to identify the most vulnerable pipelines that warrant further analysis. Depending on the nature of the seismic hazard, Metropolitan may perform a preliminary assessment using a simplified analysis based on probable ground strain and pipeline material properties. However, in some cases, a more detailed finite element model is required to fully determine the behavior of the pipe and the surrounding support strata under seismic shaking. This comprehensive analysis includes soil-structure interaction, rupture modeling, and permanent pipeline deformation.

For any pipelines that do not meet the performance objectives, mitigation measures are considered. The order and timing of projects to mitigate risks as part of the overall rehabilitation strategy are evaluated and prioritized for inclusion in Metropolitan's CIP.

Part 2 – Mitigation Measures for Existing Pipelines: Where mitigation is recommended to minimize the consequences of service disruption, the general design goals are to design pipe segments and joints that can withstand projected vertical and horizontal movement. In most cases, a simplified analysis will provide sufficient insight into seismic performance; however, in some cases, it may be necessary to analyze the pipeline and connecting structures using a more comprehensive computer model.

Existing continuous welded steel pipe with adequate wall thickness and joint welds typically perform well under significant ground shaking. Where mitigation of existing pipelines is required to achieve acceptable seismic performance, Metropolitan may use specialized earthquake resistant joints as an option. Where these joints cannot achieve acceptable seismic performance, other options may include stiffening of the joints and pipe section; and enlarged vault sections to isolate the pipe from maximum ground deformation. Metropolitan may also evaluate alternate alignment options to relocate existing pipes, if feasible, to avoid areas of known fault crossings or expected permanent ground deformation that may result in significant disruption. Where these options are not feasible and seismic risk is not within acceptable limits, Metropolitan may consider installation of isolation valves or addition of a vault with a removable pipe spool to allow quick insertion of a bulkhead to facilitate shutdown and repair of the damaged section of pipe

Part 3 – Design Guidelines for New Pipelines: The guidelines for new pipelines will be similar in concept to existing pipelines and will be developed in conjunction with several new large-diameter pipeline projects that are planned over the next 5 to 10 years.

SECTION 5 OPERATIONS COMPONENT

Metropolitan is prepared to respond to all types of emergencies through its Emergency Management and Business Continuity Operating Policy A-06. Key elements of this policy include IT Disaster Recovery, Business Continuity and Emergency Response functions. This section focuses on the Emergency Response functions due to specific steps in this area that pertain to seismic resilience.

Emergency Response Organization

Metropolitan maintains a dedicated Emergency Operations Center (EOC) that can be activated at any time to manage Metropolitan's response to a large disaster, including seismic events. The EOC is equipped with multiple modes of communication and coordinates directly with Metropolitan's Operations Control Center (OCC) and Security Watch Center (SWC), as well as with numerous external agencies. For example, the EOC would coordinate with DWR and LADWP, as well as other related agencies, in the event of one or more aqueducts being damaged by an earthquake on the San Andreas Fault, as further explained in the next section.

Metropolitan also has Incident Command Centers (ICCs) located at various facilities. These ICCs can also be activated at any time to manage localized emergencies, and will coordinate directly with the EOC during a major disaster. Metropolitan also has Damage Assessment Teams (DATs) that that can be called upon by the ICCs to conduct investigations at incident sites. The DATs consist of engineers who can assess damage and initiate engineering responses, including recommendations for short-term repairs or work-arounds and potential designs for permanent, long-term repairs.

The Emergency Response Organization (ERO), illustrated in **Figure 5-1**, is comprised of over 200 pre-designated employees who work in the EOC, the ICCs, or in the field during emergencies. ERO staff has completed specialized training that meets State and Federal requirements.

Metropolitan's emergency response structure follows the National Incident Management System (NIMS) and the State of California's Standardized Emergency Management System (SEMS).

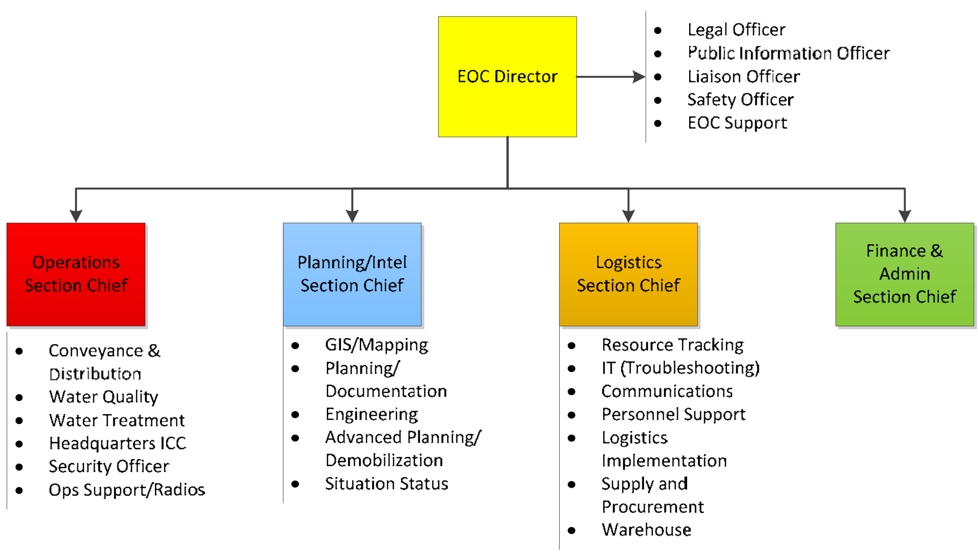

Figure 5-1: Metropolitan's Emergency Response Organization

Photographs from recent emergency exercises at the EOC

Emergency Response Training Exercises

In addition to training emergency response staff on NIMS procedures, Metropolitan regularly conducts emergency response training exercises which have often been based upon a postulated seismic event. Examples include:

- “Resilient Grid“ Functional Exercise, 19 Oct 2017
- “Can you hear me now?” Full Scale Communications Exercise, 08 Apr 2017
- “Desert Shake” Functional Exercise – 04 Nov 2015 (Metropolitan and seven other agencies)
- “Oh Susana!” Functional Exercise – 05 Nov, 2013 (Metropolitan and four other agencies)
- “Golden Guardian” Functional Exercise – 20 Jun 2012
- “California Rolling” Mini Functional Exercise – 08 Oct 2008
- “Hollywood Havoc” Functional Exercise – 04 April 2007
- “Mayhem at Mathews” Tabletop Exercise – 15 Mar 2006 (Metropolitan and four other agencies)

In 2017, Metropolitan completed a five-year exercise plan that allowed all of its member agencies to participate in at least one of Metropolitan’s annual emergency exercises during that period. Metropolitan also conducts approximately 50 tabletop and functional exercises each year. This includes three large-scale emergency exercises per year for the EOC and for each of the 12 ICCs. There are also monthly communication drills (includes Member Agency Response System (MARS) two-way radio, internal Metropolitan radio system, WebEOC updates, mass notification system, and satellite phones) with member agencies, ICCs, Treatment Plant Control Centers, and DWR facilities. These regular exercises, as well as monthly radio and communications tests with member agencies and other outside agencies, help Metropolitan to continually improve its readiness.

Emergency Response Construction Capabilities

Metropolitan maintains the capability to perform rapid repair of damaged facilities such as large pipelines for up to two simultaneous repairs. The machine, fabrication, coating, and valve shops at the La Verne

Shops are used extensively to support system-wide maintenance; to provide emergency services within Metropolitan, for member agencies, and for DWR; and to perform fee-for-service work that supports member agencies and the State Water Project. The fabrication shop can roll pipe on a 24-hour-per-day basis. In 2015, Metropolitan expanded the La Verne Shops to enable the fabrication of two pipe sections up to 12 feet (3.7 meters) in diameter simultaneously, and has been developing standardized pipeline repair drawings and shoring drawings to expedite repair operations.

Metropolitan also maintains stockpiles and materials on hand, and has its own construction equipment and crews ready to mobilize if necessary. Pre-selected urgent repair contractors can also provide additional construction support in case of an emergency. Maintaining these manufacturing and construction capabilities supports Metropolitan's efforts to efficiently operate and maintain its infrastructure and to quickly repair components or systems that may be damaged.

Pipe being rolled at Metropolitan's La Verne Shops

Metropolitan construction crews

42" x 30" adapter flange being drilled at Metropolitan's La Verne Shops

Stocks of steel plate allow Metropolitan to roll pipe of various diameters and wall thicknesses

SECTION 6 REPORTING COMPONENT

The reporting component of Metropolitan's seismic resilience strategy focuses on the following areas:

1. Record Keeping: Tracking progress and maintaining a record of expenditures
2. Annual Updates: Providing annual updates to Metropolitan's Board of Directors
3. Formal Reporting: Preparing a formal Seismic Resilience Biennial Report

Record Keeping

The Record Keeping component involves tracking progress on key seismic activities and maintaining a detailed record of all investments and expenditures related to seismic upgrade projects.

Key seismic resilience activities include the planning, engineering, operations, and Task Force component near-term goals identified in Section 8. Specific activities include:

- Special planning studies related to seismic resilience
- Seismic evaluations of structures, facilities, and regions
- Designs for seismically upgrading structures/systems and related construction activities
- Emergency response training exercises
- Development of new seismic performance objectives
- Joint efforts with external agencies through the Task Force

For each of these activities, progress will be tracked and reported on at regular intervals. In addition, the cumulative cost of capital investments in seismic upgrade projects will be tracked and reported on annually.

Annual Updates

Staff will update Metropolitan's Board of Directors on an annual basis. The annual update will focus on current seismic resilience issues, recent Metropolitan and Task Force accomplishments, and near-term goals.

Formal Reporting

The biennial report will summarize seismic resilience objectives, goals, and accomplishments; consolidate key reference material; and provide a high-level summary of the various activities related to seismic resilience throughout Metropolitan. Specific areas of emphasis will include:

- Knowledge Transfer: The biennial report will provide a convenient, comprehensive source for seismic resilience information. The report will contain key information for all seismic resilience efforts throughout Metropolitan, and will include a list of all formal Metropolitan reports on seismic issues. Individuals can use this information to familiarize themselves with Metropolitan's seismic resilience history, issues, and goals, which will make them more effective in supporting seismic resilience efforts.

- Accountability: Through annual reporting to the Board, seismic resilience programs will maintain a higher degree of visibility, focus and momentum on projects and studies that will help Metropolitan meet target goals.
- Transparency: The sharing of seismic resilience studies, projects, and performance objectives will benefit the facility planning efforts of member agencies. Seismic risk, mitigation, and projected duration of outages are complex issues that deserve adequate discussions between Metropolitan and member agencies to facilitate decisions and investments that best serve the public.

This summary report will be updated every two years.

SECTION 7 SEISMIC RESILIENCE WATER SUPPLY TASK FORCE

The City of Los Angeles has recently increased its focus on seismic risks and public safety. In December 2014, the city released the report, "Resilience by Design," which highlighted Los Angeles' earthquake vulnerabilities and laid out strategies to protect lives; improve the capacity of the city to respond to earthquakes; prepare the city to recover quickly from earthquakes; and protect the economy of Los Angeles and all of Southern California.

A concern noted in "Resilience by Design" is the importance of water infrastructure and the unique dependence of the region upon imported water supplies, all of which cross the San Andreas Fault. The report included a recommendation to fortify the imported water aqueducts by creating a Seismic Resilience Water Supply Task Force (Task Force) with the LADWP, Metropolitan, and DWR.

In August 2015, the three agencies formed the Task Force for the purpose of collaborating on studies and mitigation measures to improve the seismic resilience of imported water supplies to Southern California. The Task Force is comprised of managers and staff from the planning, engineering, and operations functional groups of each agency, and includes executive management on a steering committee. The Task Force also coordinates with other agencies and utilities.

The Task Force created a structure (**Figure 7-1**) that includes functional sub-teams that will focus on aqueduct assessments and mitigation, emergency response, and public relations in the near-term. The Task Force also recognized the benefit of long-term collaboration regarding 'non-aqueduct' assessments and mitigation, and agreed to discuss such issues as they arise.

The initial Task Force goals include:

- Establishing a common understanding about individual agency aqueduct seismic vulnerability assessments, projected damage scenarios, and planning assumptions
- Revisiting historical assumptions regarding potential aqueduct outages due to seismic events
- Discussing opportunities for improving the seismic resiliency of Southern California's imported water supplies through multi-agency cooperation

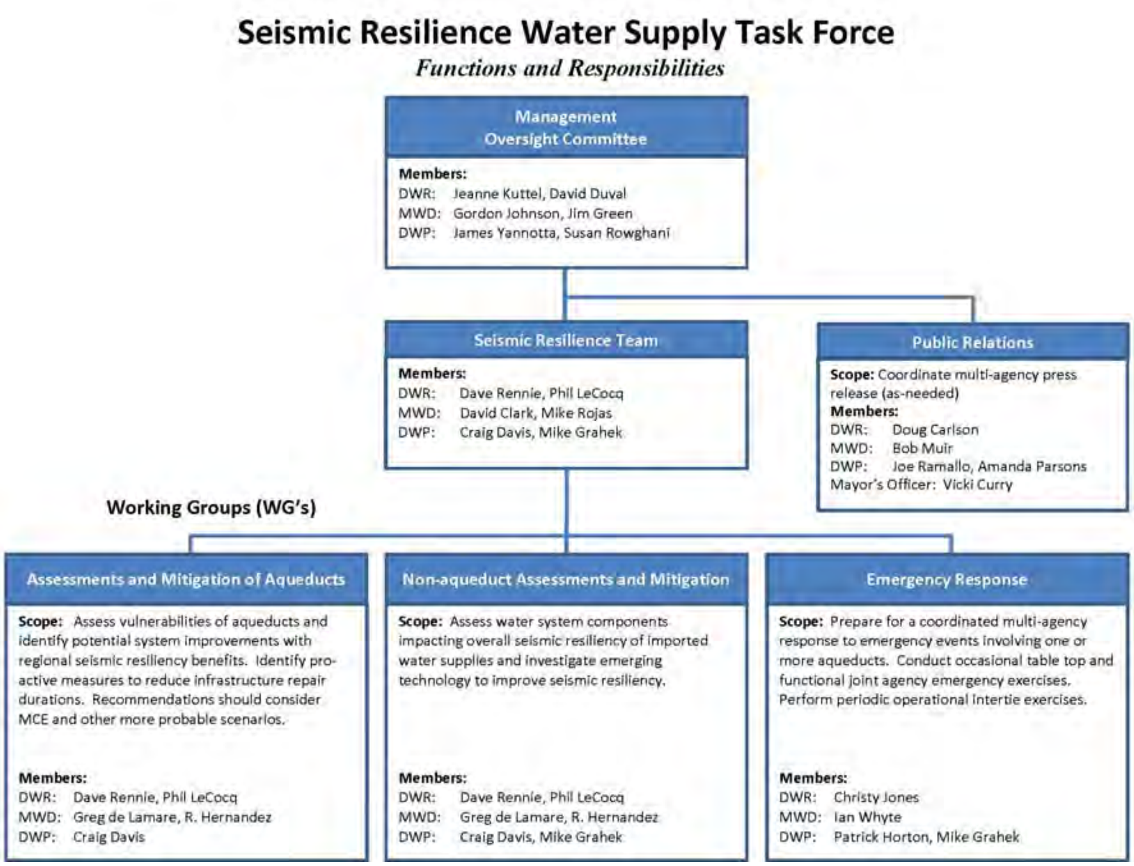

Figure 7-1: Seismic Resilience Water Supply Task Force

One of the initial activities for the Task Force was to conduct a workshop that would allow the three agencies to establish a common understanding about each agency's seismic vulnerabilities; revisit historical planning assumptions; and identify action items that would lead to increased seismic resilience moving forward. The workshop is summarized below.

2016 Aqueduct Workshop

On March 30, 2016, the Task Force held an Aqueduct Workshop at Metropolitan's Headquarters Building in Los Angeles. The purpose of this workshop was to discuss potential damage to Southern California's imported water aqueducts from a major seismic event on the San Andreas Fault. The discussion focused specifically on the Great Southern California ShakeOut Scenario (ShakeOut) of a M7.8 earthquake, developed by the U.S. Geological Survey (USGS) and many partners. The workshop format allowed for a candid exchange of information and ideas between staff from the three agencies, along with LADWP's Seismic Resilience and Sustainability Program's Expert Panel that included experts from industry and academia.

Participants were asked to consider preparations for, and response to, the ShakeOut Scenario from a regional perspective. Specifically, participants were asked, "If all aqueducts were owned and operated by a single agency, then what steps should be taken now to mitigate potential damage, and what would the priority of repairs be following a major seismic event to most rapidly restore imported water deliveries to the region?" This focus on actions that would best serve the region led to productive discussions and practical recommendations for the three agencies to improve the resilience of imported water supplies.

The assembled team concluded that for a M7.8 ShakeOut Scenario event on the southern portion of the San Andreas Fault, the recovery times would exceed historic planning assumptions:

- Restoration of full aqueduct capacities could take more than six months
- Restoration of partial aqueduct flows could take at least two months

The March 30, 2016 Task Force Workshop at Metropolitan's Headquarters Building

When considering this specific scenario from a regional perspective, the participants concluded that residents within Metropolitan's service area would be best served if the three agencies:

- Implement recently identified mitigation projects on the Colorado River Aqueduct and Los Angeles Aqueduct
- Prioritize known vulnerabilities on the Colorado River Aqueduct, Los Angeles Aqueduct, and the State Water Project
- Execute an agreement to allow for a coordinated response to emergency events
- Share resources when responding to emergency events
- Focus initial repair efforts on the State Water Project's West Branch and the Colorado River Aqueduct*

(*This is based on a ShakeOut-type event; it is recognized DWR will also have a priority to serve other customers on the East Branch)

LADWP's Seismic Resilience and Sustainability Program's Expert Panel noted the significance of the nation's largest municipal utility, largest water wholesaler, and largest state-owned water agency joining together to address a major hazard for the first time, and encouraged the Task Force to continue working together long into the future. The assembled team agreed that Southern California could become better prepared for seismic events and that the Task Force should continue to facilitate coordinated vulnerability assessments, evaluate mitigation options, and develop agreements that allow coordinated emergency responses to major seismic events. It was clear that common issues could be studied more efficiently together and there was a consensus for the Task Force to continue to maintain the momentum achieved through this workshop. Although the regional challenge of achieving a greater level of seismic resiliency is significant, the consensus was that it would be achievable through the continued, dedicated efforts of the Task Force.

Future Task Force Activities

To continue the momentum built during the collaborative workshop, the Task Force agreed to conduct conference calls every two months and to initiate a repeating 5-year cycle of planning, executing, and reporting on collaborative goals, activities and accomplishments. This approach is aimed at providing effective management of long-range actions and ensuring task force stability.

The first cycle has included preparation of a detailed report that summarized the 2016 Workshop and identified goals for the period between April 2017 and March 2022. The second cycle will report on progress achieved between 2017 and 2022, and will identify goals for the period between 2022 to 2027.

The high-level goals for 2018 to 2019 are included in Section 8 of this report.

SECTION 8 SEISMIC RESILIENCE PERFORMANCE OBJECTIVES AND NEAR-TERM GOALS

This section summarizes Metropolitan's established performance objectives for the various components of seismic resilience, along with corresponding near-term goals. The goals listed are those that are anticipated to be completed in calendar years 2018 and 2019.

Established Performance Objectives and Near-Term Goals:

- System Level
- Facility Level
- Emergency Response
- Task Force

Other Near-term Goals:

- Establish Additional Performance Objectives
- Develop a Standard Approach for Evaluating Non-Structural Elements
- Enhance Member Agency Planning Efforts
- Seek Funding for Identified Projects
- Support California WaterFix

Established Performance Objectives and Near-Term Goals

Seismic resilience performance objectives are summarized in this section along with the corresponding near-term goals.

System Level

System-level seismic resilience performance objectives and near-term goals focus on two areas: System Flexibility and Regional Supply Interruption/Emergency Storage.

System Flexibility

There are two primary components of system flexibility that contribute to seismic resilience:

1. Operational flexibility - the ability to accommodate short-term changes in regional supply, water quality, or member agency demands, and
2. Delivery flexibility - the ability to maintain deliveries to member agencies during single regional facility planned or unplanned outages.

Metropolitan will continue to develop a demand-driven, flexible regional system aimed at meeting demands, while reducing the impacts of regional infrastructure outages. Regional delivery flexibility improvements will be achieved through demand-driven projects.

System Flexibility Goal	
2019 Goal:	Conduct Rialto Pipeline Alternative Supply Needs study
This study will identify potential near-term and long-term options to meet municipal and industrial (M&I) demands supplied exclusively from the Rialto Pipeline system in the event of a disruption of supplies from the California Aqueduct, East Branch.	

Emergency Storage

Performance Objectives: Metropolitan's objectives for emergency storage include maintaining a six-month supply of water to account for interruption of imported water supplies (assuming a 25% reduction at the retail level).

Emergency Storage Goals	
2019 Goal:	Complete a re-evaluation of Metropolitan's emergency storage needs
This study will re-evaluate Metropolitan's emergency storage requirement based on updated assumptions on potential outage durations for the State Water Project and the Los Angeles Aqueduct. The latest projections for the worst case scenario are that Metropolitan's Colorado River Aqueduct can be repaired within 6 months, LADWP's Los Angeles Aqueduct within about 18 months, the West Branch of the SWP within 6-12 months and the East Branch of the SWP within 12-24 months.	
2019 Goal:	Complete a comprehensive evaluation of Metropolitan's storage programs
This comprehensive evaluation will review all existing storage programs within Metropolitan	

Facility Level

Facility-level seismic resilience performance objectives and near-term goals are categorized based on functionality of facilities: essential facilities related to water delivery; supporting facilities with permanent staff, such as administration buildings; and supporting facilities without permanent staff, such as warehouse facilities.

Essential Facilities (related to water delivery)

Performance Objectives: Performance objectives for essential facilities include maintaining operation with minimum interruption after design-level events and controlling structural damage to facilitate recovery after extreme events.

Essential Facility Goals	
Goal 1:	Complete construction of approved seismic upgrade projects
• Carbon Creek Pressure Control Structure (2018) • Ten Control Structures along the Allen McColloch Pipeline (2018) • Diemer Administration (Control) Building (2019) • Five CRA Pumping Plant Switch Houses (2019)	
Goal 2:	Conduct studies, and complete design of approved upgrade projects
• Define the scope and approach for assessing potential seismic-induced damage to Metropolitan's water conveyance and distribution pipelines (2018) - The purpose of the damage assessment is to estimate the number and severity of pipeline breaks and leaks during major earthquakes, and identify pipelines with the greatest risk for seismic damage. The results of the study will provide input into Metropolitan's emergency response planning activities, and will help prioritize future pipeline seismic resilience enhancements. • Design of seismic upgrade for Weymouth West Wash Water Tank (2018) • Design of seismic upgrade for Diemer West Filter Building (2018) • Complete evaluation of options, design, and award of construction contract to strengthen the CRA Whitewater Tunnel No. 2 (2019) - This work will include strengthening shallow tunnel sections near the portals, improving tunnel access at the west portal, prequalifying tunnel repair contractors, stockpiling steel sets, and pre-designing tunnel repair elements. • Investigate options to improve emergency raw water bypass capabilities at Skinner, Weymouth, Jensen and Mills Water Treatment plants (2019) • Vulnerability study of CRA electric transmission and distribution systems (2019) • Design of seismic upgrade for the original portion of the Water Quality Lab in La Verne and the Weymouth Administration Building (2019)	

Supporting Facilities with Permanent Staff

Performance Objectives: Performance objectives for support facilities with permanently assigned staff include controlling structural damage to prevent casualties and severe injuries under design-level events and maintaining structural stability to prevent catastrophic collapse under extreme events.

Supporting Facilities (with permanent staff) Goals	
Goal 1:	Expedite construction of approved seismic upgrade projects
• Headquarters Building seismic upgrades (award construction contract in 2018)	
Goal 2:	Complete approved studies and seismic upgrade designs
• Seismic upgrade to Field Engineering Building at La Verne (2019)	

Supporting Facilities without Permanent Staff

Objectives: Performance objectives for support facilities without permanently assigned staff include controlling structural damage to facilitate recovery after design-level events and maintaining structural stability to prevent catastrophic collapse under extreme events.

Goals: Metropolitan's near-term goal for improving the seismic resilience of support facilities without permanently assigned staff is to continue exploring opportunities of integrating seismic upgrade work of these relatively minor structures with future capital projects at the facility. At this time, no specific goals have been identified in this area.

Emergency Response

Objectives: Metropolitan's objective is to maintain an effective emergency response organization and support facilities to ensure Metropolitan is prepared to respond to significant earthquakes. Regular training is conducted to ensure staff is prepared for actual events. Metropolitan maintains shop and construction crew capabilities to complete the repair of two simultaneous large diameter pipeline breaks within seven days. This capability is augmented by Metropolitan's ability to re-deploy its contractors and to call upon other agreements to repair four additional large diameter pipe breaks simultaneously within seven days (as well as repair other facility damages). These capabilities ensure Metropolitan is prepared to respond to significant earthquakes.

Emergency Response Goals	
Goal 1:	Prepare and conduct emergency exercises
• Conduct a joint agency workshop to prepare a draft Joint Agency Response Plan (2018) • Conduct high-level training for DWR, LADWP, and MWD staff on the Joint Agency Response Plan (2019) • Run a functional exercise on the Joint Agency Response Plan (2019)	
Goal 2:	Execute a MOU to allow for a coordinated emergency response
• Prepare draft MOU and submit for review (2018) • Secure LADWP, Metropolitan, and DWR approval for the MOU (2019)	

Task Force

Task Force Goals	
2018 Goals:	Collaborative LADWP, Metropolitan, and DWR Goals
• Discuss the applicability of lessons learned from seismic events in Japan, Chile, New Zealand, and Mexico • Compare each agency's approach to conducting seismic assessments • Meet with Southern California Edison (SCE) and Southern California Gas Co. to discuss the potential vulnerabilities of aqueduct power systems • Conduct workshop to explore potential aqueduct interties	
2019 Goals:	Collaborative LADWP, Metropolitan, and DWR Goals
• Establish a leadership structure for a coordinated response to major events • Finalize a three-agency database of available emergency response resources • Conduct a three-agency table top emergency exercise • Develop a ShakeOut Scenario Response and Restoration Plan • Conduct a second three-agency functional emergency exercise that includes energy utilities	

Other Near-Term Goals

Additional seismic resilience goals Metropolitan plans on achieving during 2018 and 2019 include:

1. **Develop a Standard Approach for Evaluating Non-Structural Elements (2019)**

   The Seismic Upgrade Program was expanded from its focus on pre-1990 above-ground structures to include post-1990 structures, partially buried structures, and non-structural components in essential facilities. The existing approach to evaluating pre-1990 structures is also applicable to the post-1990 and partially buried structures. However, a standard approach needs to be developed for evaluating the non-structural components within existing facilities, which involves equipment anchorages and bracing for piping, ducts, and cable trays.

2. **Establish Additional Performance Objectives (2019)**

   Metropolitan intends to establish seismic resilience performance objectives in the following areas:

   a) New pipelines

   b) Retrofit of existing Metropolitan pipelines, typically concurrent with rehabilitation projects

   c) New and existing tunnels

   Metropolitan is now in the process of developing a more comprehensive strategy for incorporating seismic mitigation into the design of its pipelines and tunnels. Although it is possible to clearly define performance objectives for above-ground structures, this process is more complicated for pipelines and tunnels for two reasons: 1) The performance of a pipeline or tunnel subjected to seismic forces is less well-defined than with structures, and 2) The performance needs of specific pipelines, pipeline segments, or tunnels vary widely due to Metropolitan's supply flexibility and the varied reliance on imported water by member agencies. Metropolitan will explore these issues in greater detail as it moves ahead with major capital programs, including the PCCP Rehabilitation Program. It is expected that by December 2019, Metropolitan will have established an approach for addressing seismic vulnerabilities during pipeline and tunnel rehabilitation projects, and for new pipeline and tunnel design efforts.

3. **Investigate the Potential for Developing a Model to Prioritize Pipeline Rehabilitation (2019)**

   The prioritization model will seek to optimize the sequence of pipeline repairs to achieve the greatest risk reduction for every dollar invested. The prioritization model would take into account multiple risk factors including seismic risk exposure, pipeline condition, consequence of failure in terms of damage to key facilities (e.g., hospital), difficulty of repairs, system flexibility, and cost of repairs.

4. **Enhance Member Agency Planning Efforts (2019)**

   Development of the following documents will support member agency planning efforts regarding new facilities and emergency response programs:

   a) Summary of seismic performance objectives by facility class; examples of recent seismic upgrade projects; and identification of open items

   b) Summary of projected outage durations for Metropolitan facilities under "Operational", "Design", and "MCE" earthquake scenarios

5. **Seek Approval for Detailed Seismic Studies (Ongoing)**

   Under the ongoing Seismic Upgrade Program, Metropolitan will assess the options for seismic upgrades to 28 structures identified as seismically deficient. These projects will be considered for inclusion in Metropolitan's Capital Investment Plan.

6. **Support California Water Fix (Ongoing)**

   Metropolitan will continue supporting the California WaterFix to increase seismic resilience of the Bay-Delta portion of the State Water Project.

Appendix 1

Key Seismic Resilience Achievements

This page intentionally blank.

Metropolitan has made significant improvements in the overall seismic resilience of its water system over the past few decades. These achievements include:

1971	Earthquake Committee formed to assess damage and recommend improvements
1976	Metropolitan's Emergency Response Plan formally adopted
1983	Member Agency Response System (MARS) established
1993	Incident Command Centers (ICCs) established at each treatment plant and a formal engineering response chart adopted for the Damage Assessment Teams (DATs)
1995	Formal Business Resumption Plan developed
1996	Seismic upgrade of CRA Pump Houses completed
1999	Construction of Diamond Valley Lake completed
2004	South slope stability improvements completed at Diemer
2005	Construction of new Lake Mathews Tower completed
2010	Jensen Administration Building seismic upgrade completed
2010	Construction of the Inland Feeder completed
2011	Seismic upgrade of Mills Electrical Buildings 1 & 2 completed
2013	Seismic upgrade of Diemer Finish Water Reservoir completed
2013	Diemer East Wash Water Tank seismic upgrade completed
2014	Seismic upgrade of Weymouth Filter Buildings 1 and 2 completed
2014	CRA seismic assessment confirmed historical assumptions for duration of worst-case outage of the CRA
2015	Seismic upgrade of Jensen Washwater Tanks 1 & 2 completed
2015	Seismic upgrade of Weymouth East Wash Water Tank completed
2015	Task Force formed to enhance seismic resilience of imported water supplies
2017	Seismic upgrade of Diemer East Filter Building completed

Note: Metropolitan has invested over $250M in seismic upgrade projects since 1998.

The California Department of Water Resources has also taken steps to improve the seismic resilience of Southern California's imported water systems, including:

1997	Construction of new Outlet Tower at Silverwood Lake completed
2018	Lake Perris Dam improvements completed

This page intentionally blank.

Appendix 2

Modern Era Earthquakes over M6.3 Within or Near Metropolitan's Primary Service Area

This page intentionally blank.

Southern California has experienced at least six earthquakes within or near Metropolitan's service area and with magnitudes greater than M6.3 during the past hundred years.

Date	**Event Location**	**Fault**	**Magnitude**
April 21, 1918	San Jacinto	San Jacinto	6.7
Mar. 10, 1933	Long Beach	Newport-Inglewood	6.4
Feb. 9, 1971	San Fernando	Sierra Madre	6.5
June 28, 1992	Landers	San Andreas	7.3
Jan. 17, 1994	Northridge	Northridge Thrust	6.7
Oct, 16, 1999	Hector Mine	Lavic Lake Fault	7.1

MWD
METROPOLITAN WATER DISTRICT OF SOUTHERN CALIFORNIA

COLORADO RIVER AQUEDUCT

TECTONIC ALLOWANCE ORIGINAL INTENTION INVESTIGATION

1 March 2016

Purpose and Objective

Historic documents have mentioned that the designers of the Colorado River Aqueduct (CRA) incorporated "measures in their engineering designs to minimize the impacts on the flow through the CRA due to future vertical displacements across the key fault traces mapped at that time. **The measures included an additional 0.8 m (2.5 ft) of drop beyond that required by siphon losses at… three fault crossings**" (Report 1484). "In each siphon [Big Morongo and San Andreas] approximately 2.5 feet of additional grade was allowed to provide for adjustment in slope if future movement should occur" (Contract Number 149).

Figure 1 shows the location of each of the siphons in question.

The question was raised regarding the specifics of how this was accomplished. This document will describe investigation into whether this allowance was incorporated, the mechanism by which this allowance was included, summarize historical records suggesting such an allowance, and recommend field investigations which can confirm this analysis.

Figure 1
Overview Map

Observances of Tectonic Allowance

Record drawings for the Colorado River Aqueduct were explored to identify any occurrences or explanation for design Hydraulic Grade Line (HGL) at the Big Morongo Siphon, San Andreas Siphon and Casa Loma Siphon. The first observance of the allowance is found in the hydraulic profiles prepared as a part of the original record drawings of the Colorado River Aqueduct in 1935. Selected copies are included at the end of this document.

A discontinuity is observed in the HGL, dropping by a notated 2.5 feet at the beginning of the Big Morongo Siphon, San Andreas Siphon, and Casa Loma Siphon. The HGL is highlighted in red on Figure 1, with the 2.5-foot drop circled.

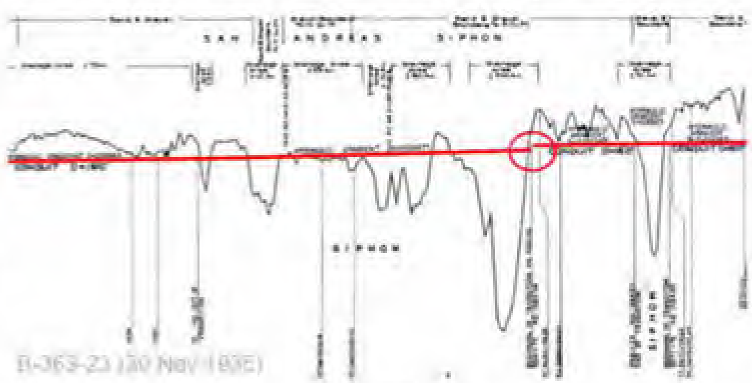

Figure 1
Original 1935 San Andreas Siphon Plan and Profile

A second observance of the allowance is found in the record drawings associated with the late 1950's construction of the second barrel for the CRA siphons (Specification Numbers 504 and 509). As before, selected copies are included at the end of this document. The plan and profiles found in the second barrel siphon record drawings show two parameters corresponding to hydraulic grade at the downstream transition structures, as follows:

- "HG. El.", assumed to be an acronym for Hydraulic Grade Elevation, and assumed to refer to the pressure head at design flow
- "WS El.", assumed to be an acronym for Water Surface Elevation, and assumed to refer to the water surface under free-surface flow conditions at design flow

In the siphon, the HGL is observed to be above the soffit of the pipeline, indicating the pipeline is designed to be under pressurized flow. Upon entering the transition structure, the HGL is below the top of the transition structure walls as free surface flow is designed for.

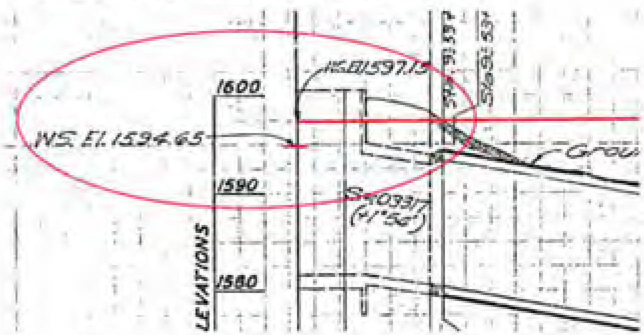

Figure 2
Big Morongo Siphon Second Barrel Plan and Profile

As shown on Figure 2, the Water Surface Elevation line in the outlet transition structure is depicted 2.5 feet below the Hydraulic Grade Elevation line, as circled in red. For other transition structures, the Hydraulic Grade Elevation line meets the Water Surface Elevation line, as shown on Figure 3 for Thousand Palms Siphon.

A second barrel was not constructed at Casa Loma Siphon according to the original plans, so no corresponding record drawing was identified.

Staff from the Hydraulics team confirmed via calculation that the headloss depicted by the HGL is consistent with the major and minor losses shown in the record drawings for the design flows.

A third observation of the allowance is found in the hydraulic profiles. While not called out numerically as on the previous two sources, the hydraulic profiles depict a slope offset at the Big Morongo and San Andreas Siphons of a much greater magnitude than those observed for other siphons. This is depicted in two figures on the following page.

It is understood that the design philosophy for each siphon was to size the losses across each siphon to maintain the free surface flow HGL across the siphon. This can be graphically observed in Figure 4 as shown by the red dashed line highlighting the HGL matching the canal or conduit slope upstream and downstream of the siphon.

At Big Morongo and San Andreas siphons, an offset of 2.5 feet is observed between the slope upstream of the siphon and the slope downstream of the siphon. Figure 5 highlights this in blue for Big Morongo Siphon.

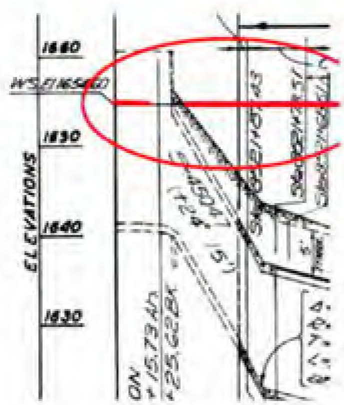

Figure 3
Thousand Palms Siphon Second Barrel Plan and Profile

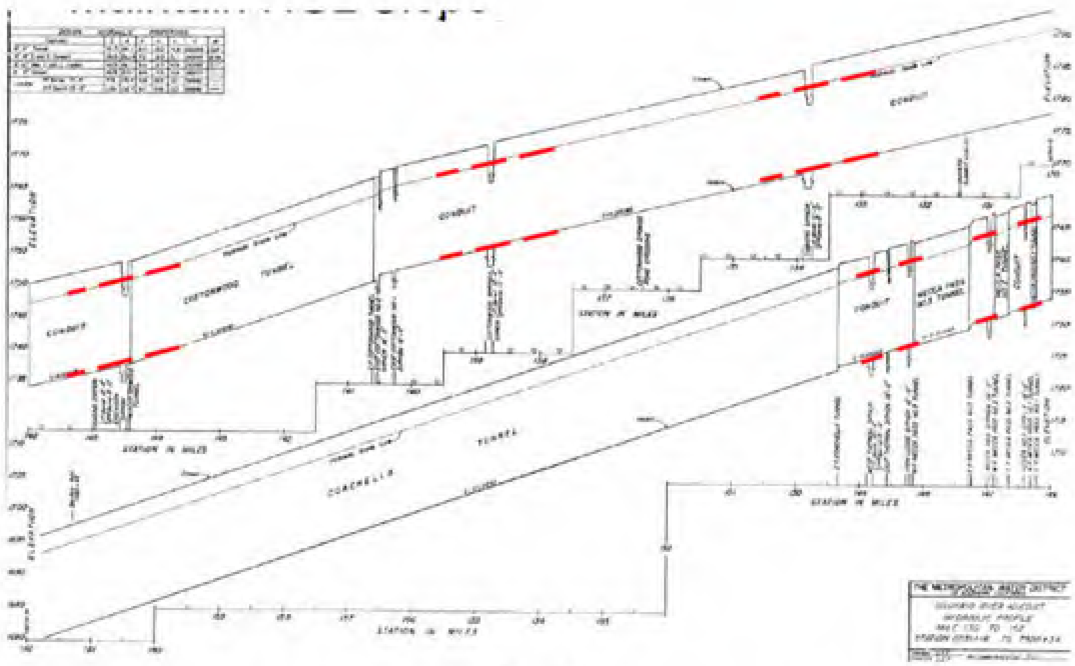

Figure 4
Siphon HGL Slope Consistent with Aqueduct Slope

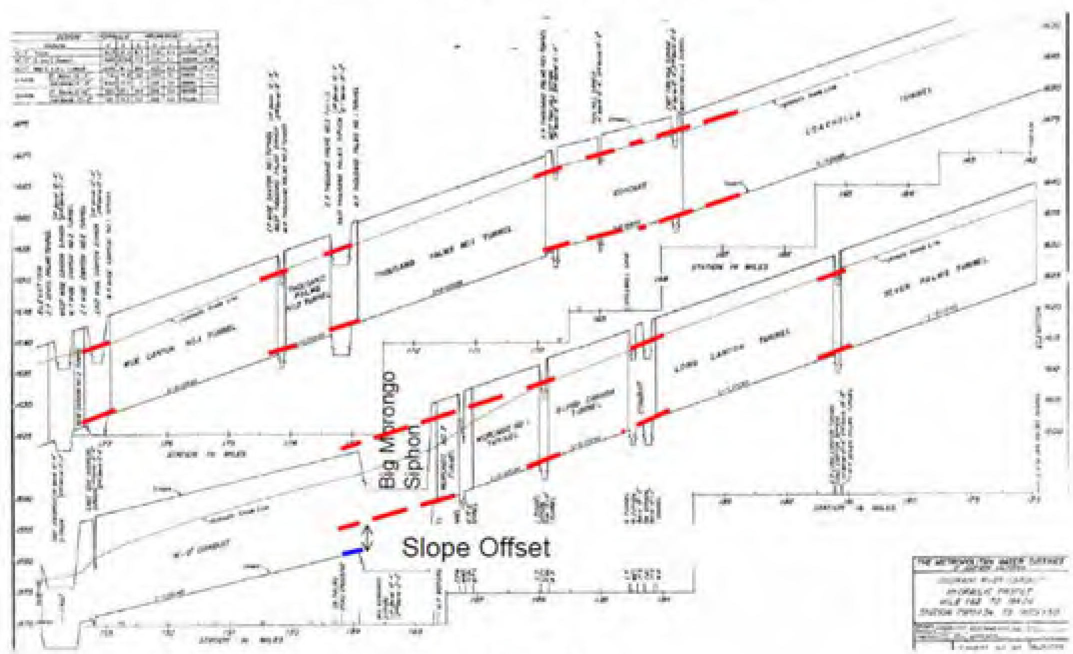

Figure 5
Siphon HGL Slope at Big Morongo Siphon

March 2016 3 CRA Tectonic Uplift Allowance

This last set of observances of the 2.5-foot allowance may provide a suggestion of the designer's thoughts on the effect of the allowance. The Hydraulic Grade Line observed on the profiles gradually drops relative to the invert elevation though the Morongo Number 1 Tunnel and the Morongo Number 2 Tunnel, and in the conduit immediately upstream of the San Andreas Siphon. While dimensions nor elevations are called out on this profile, the depth at the outlet to the Morongo Number 2 Tunnel can be measured on the drawing as 8.9 feet, and the depth at the entrance to the San Andreas Siphon can be measured on the drawing as 7.8 feet.

Previous Surveys

Based on the contract document, construction on Big Morongo Siphon and San Andreas Siphon was started on 5 Feb 1935 and concluded on 16 Sep 1936, with work activities completed by May 1936.

In February and March 1935, a construction staking survey was conducted. Included in the survey notes are an adjustment to the slopes consistent with the markups included in the contract documents (Contract 149). This timing is consistent with the start of construction.

In August 1937, after construction of the CRA, the as-built survey was conducted to set brass caps on the transition structure as permanent benchmarks. Benchmarks established include:

- a manhole at Station 9316+46
- the outlet transition structure for Big Morongo Siphon at Station 9353+15
- the outlet transition structure for East San Andreas Siphon at Station 9581+25 (referred to as "Outlet Siphon" in survey notes)
- the inlet transition structure for San Andreas Siphon at Station 9591+75
- a manhole at Station 9595+00
- the outlet transition structure for San Andreas Siphon at Station 9625+75
- the outlet transition structure for West San Andreas Siphon at Station 9651+75 (referred to as "small siphon" in survey notes)

These are recorded in Field Book 2740. No mention is made within the survey notes of any measurement of invert elevations of the pipeline or transition structure, so any inferences made to the invert elevation require the assumption that the transition structure dimensions are consistent with the planned dimensions appearing on the construction plans (19.17 feet for the Big Morongo Siphon outlet transition structure 18.96 feet for the Big Morongo Siphon inlet transition structure and both San Andreas Siphon transition structures).

In 1998, the Casa Loma Siphon first barrel was surveyed as a part of an as-built survey prepared for construction of concrete encasement between Stations 11073+45 and 11073+93 related to work on the Inland Feeder. The survey notes mention replacement of the pipeline, but do not appear to include any survey of invert elevations.

In 2008, the San Jacinto Diversion Structure, which originated as the inlet transition structure to the Casa Loma Siphon first barrel, was surveyed as a part of establishing NAVD 1988 elevations in the area. While the survey notes do not include invert elevations, they do include the weir elevation, which can be used to estimate the invert elevation based on the record drawings.

In 2014, a settlement study was conducted by Survey at San Andreas Siphon and Big Morongo Siphon to determine the difference in elevation between the inlet and outlet transition structures. The survey only measured the relative difference between the benchmarks set on the inlet and outlet transition structures of each siphon in the August 1937 survey. The difference in elevation between the inlet and outlet structure benchmarks is presented in the table below, suggesting no changes in relative ground movement in the intervening eight decades.

Table 1 1934 and 2014 Survey Comparison

Siphon	May 2014 Survey (feet)	August 1935 Survey (feet)	Difference (feet)
Big Morongo	7.90	7.90	0.00
San Andreas	6.64	6.68	-0.04

Source: Survey Field Book 2740 and Survey Note 1001-29 042

As with the previous surveys, no measurement was made of the invert elevations, so it is not possible to verify that the slope of the canal includes the 2.5-foot slope offset upstream of the siphon directly from survey measurements.

However, using the derived measurements developed as a part of IMDC (ultimately from the design drawings), the slope offset can be calculated. If the difference in elevation between the invert elevations at the inlet and outlet transition structures is 2.5 feet greater than that calculated based on the design slope for the siphon, then the survey data would confirm the tectonic allowance is included in the slope offset. Based on the notes included in the contract document and the slopes appearing on the hydraulic profiles, a slope of 0.00077 was used for design of the lengths of the CRA siphons. The table below presents the calculation, including several other siphons for comparison.

Table 2 Slope Offset Calculation

Siphon Name	Transition Structure Invert Elevation: Upstream (ft-msl '88)	Transition Structure Invert Elevation: Downstream (ft-msl '88)	Drop per Survey (feet)	Drop per Slope (feet)	Slope Offset (feet)
Cottonwood Spring Siphon	1,759.21	1,758.60	0.61	0.46	0.15
End Wash Siphon	1,740.23	1,740.12	0.11	0.45	-0.34
Iron Ledge Siphon	1,729.36	1,728.93	0.43	0.23	0.20
East Thermal Siphon	1,728.27	1,727.90	0.37	0.14	0.23
West Fan Hill Siphon	1,657.67	1,657.03	0.64	0.42	0.22
Thousand Palms Siphon	1,645.53	1,643.93	1.60	1.46	0.14
Whitehouse Canyon Siphon	1,593.82	1,593.27	0.55	0.40	0.15
Big Morongo Siphon	1,591.85	1,584.31	7.54	4.94	2.60
East San Andreas Siphon	1,574.16	1,573.69	0.47	0.27	0.20
San Andreas Siphon	1,573.22	1,566.84	6.38	2.62	3.76

Notes:
(1) Design slope of 0.00077 does not appear on most siphons on most hydraulic profiles, but was checked on the individual plan and profiles for all of the siphons listed in this table

As shown in Table 2, most of the siphons exhibit a deviation in surveyed slope from the design slope of between 0.1 and 0.2 feet. Big Morongo Siphon and San Andreas Siphon slope offsets of more than 2.5 feet each, showing that the slope across each of these siphons is greater than that required to meet the design slope for the siphon of 0.00077. It should be noted that the slope offset for San Andreas Siphon is calculated as 3.76 feet, 1.26 feet greater than the 2.5 feet suggested by the allowance. This may suggest the suggested mechanism for accomplishing the allowance is incorrect, or there may be other factors at play here.

While survey data has not explicitly measured the invert elevations at any point following the construction of these siphons, this calculation is based on the assumption that the siphon transition structures were constructed consistent with the construction plans. If the internal height of the transition structures is in doubt, survey of the invert elevations of the transition structures could be of value.

Field Observations

Given the lack of level sensors along the CRA, Water Supply Operations (WSO) staff have conducted several field investigations of depths along the CRA during periods of constant flow. These field investigations generally consist of one or two staff recording single measurements of depth at several manholes and transition structures between Hinds Pumping Plant and San Jacinto Tunnel.

Under the design flow of 1,605 cfs, the normal depth is designed as 12.96 feet in the most frequently used cut and cover conduit cross-sections, and 13.17 feet in the most frequently used tunnel sections. Figure 1 presents results from the field investigation conducted on 20 March 2013, with flow conditions near design flows.

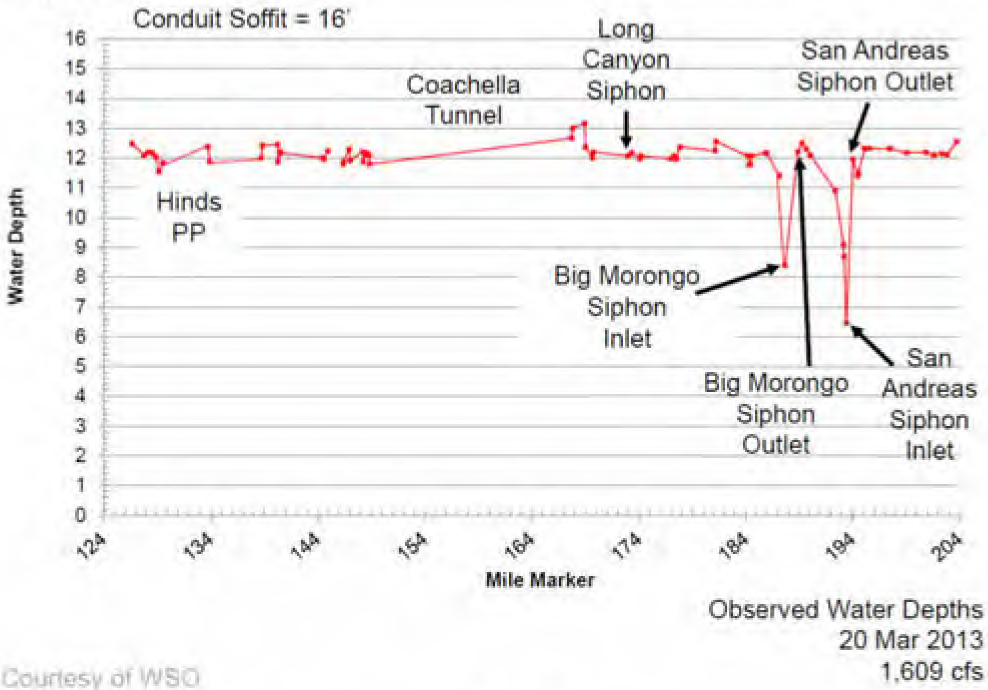

Figure 1
Observed Water Depths at Design Flow

The depth at the San Andreas Siphon and Big Morongo Siphon transition structures consistently stand out with observed water depth lower than the other siphons, dropping to less than 7 feet and less than 9 feet, respectively. These depths are fairly consistent with the depths of 7.8 feet and 8.9 feet observed in the design hydraulic profile discussed at the end of Section 0.

Mechanism

Some possible ideas that could have been incorporated include sizing the diameter of these siphons larger (reducing the headloss across the siphon) or including some type of weir structure.

It is surmised that the mechanism used for incorporating the additional head was to build the inlet transition structure 2.5 feet above the elevation at which the structure would have been constructed without the slope offset. Given that the pressurized pipeline within the siphon can change slope without impacting the hydraulics beyond minor losses, the slope of one of the stretches of pipeline could be raised to achieve a 2.5-foot elevation increase. The contract document suggests this -"The slope given in the hydraulic properties [0.00077] does not include the additional grade allowed to provide for adjustment if future earth movement should take place." (Contract 149)

An exaggerated demonstration of this mechanism is shown in Figure 1. The existing profile of the aqueduct, including the 2.5 foot allowance, is shown in black. A red line, lower at the upstream end of the siphon has been added to shown the 2.5-foot lower starting invert without the allowance. The blue line shows what the initial slope in the siphon would have been in the first pipeline segment without the allowance.

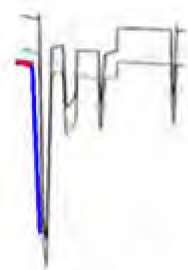

Figure 1
Surmised Design Mechanism

Further, exploring the different versions of the drawings prepared prior to construction suggests the addition of the grade as a slope change. Eight different record drawings are present in EDMS between August and December 1934 (the notice for bids was released 5 December 1934.) These partially correspond to four different construction methodologies and material choices prepared prior to the bid notice (jointed cast-in-place concrete, pre-cast concrete, above ground steel pipe, and buried steel pipe). Ultimately, jointed cast-in-place concrete was selected at the time of the bid notice. The upstream invert elevations of the transition structure in some of the drawings prepared in November 1934 have been raised by 2.5 feet from the August 1934 drawings, with differing slopes (however, each of the differing construction methodologies uses different slopes), with the height of the transition structures maintained between the different drawings. It should also be noted that the 2.5 foot allowance is observed on drawings dating back to 1933, so the allowance was likely planned for prior to 1934.

Assuming the head constraints on the design of the CRA would have been established first at the downstream end (either at the tunnels or of the elevation of Lake Mathews), this would suggest that if the allowance had not been included at each siphon, the CRA upstream of all three upstream siphons could have been designed 7.5 feet lower in elevation, with the lift at Hinds Pumping Plant reduced by 7.5 feet.

Conclusions

In review of record drawings and contract documents associated with the CRA, a tectonic allowance of 2.5 feet of HGL has been included in the design of Big Morongo Siphon, San Andreas Siphon, and the Casa Loma Siphon. Based on the above investigation into this allowance, it is believed that the mechanism for accomplishing the allowance is a slope offset in the invert elevation slope, accomplished by an increased slope in the pressurized pipeline segments within these siphons.

Based on available records, invert elevations have never been surveyed at Big Morongo Siphon, San Andreas Siphon, and the first barrel of the Casa Loma Siphon. Having invert elevation survey data will not prove the mechanism any further than currently shown on record drawings. However, if the internal height of the transition structures is in doubt, survey of the invert elevations of the transition structures could be of value.

In addition, internal inspection of the cast-in-place concrete pipeline and associated joints, as well as internal survey to determine any localized movement, may be desired for non-hydraulic reasons.

Differential survey between the inlet and outlet transition structures would likely be of little value beyond that already provided in 2014. Two additional levels of survey could be conducted—a survey of just the invert elevations of the transition structures, requiring minimal de-watering, and a survey and inspection of the entirety of the siphons, requiring full dewatering.

Estimates of effort for survey of the invert elevations in just the transition structures would be 24 staff hours plus minimal dewatering, and effort for the full siphon survey of the entire length of the two siphons would be 200 staff hours, plus staff for full dewatering.

References and List of Record Drawings

The following table lists record drawings and documents used in preparation of this analysis.

Appendix 4

Summary of Damage to Metropolitan Infrastructure from Past Earthquakes

This page intentionally blank.

Metropolitan experienced a significant amount of damage to its infrastructure during both the 1971 San Fernando and 1994 Northridge earthquakes. Both of these seismic events primarily impacted the Jensen Water Treatment Plant. Engineering prepared summary reports for both events. The information below represents a convenient summary of what may be found in "Report of Structural Damage to Joseph Jensen Filtration Plant, Earthquake of February 9, 1971" (Report No. 891C), "Historical Documentation of the Jensen Plant Earthquake Disaster of February 9, 1971" (Report No. 909), and "Damage and Repair Report for Joseph Jensen Filtration Plant, Northridge Earthquake of January 17, 1994 (October 1994).

1971 SAN FERNANDO EARTHQUAKE

The San Fernando earthquake struck the greater Los Angeles region in the early morning of February 9, 1971. The thrust earthquake, which had a moment magnitude between 6.5 and 6.7, caused severe damage in the northern San Fernando Valley, with extensive surface faulting to the south of the epicenter. The epicenter was approximately 6.8 miles from the Jensen Plant.

Metropolitan experienced widespread damage at the Jensen Plant. This included a severe break to a 72" Influent Conduit and damage to various structures including the Administration Building, Finished Water Reservoir, Access Tunnel, Mixing and Settling Basins, and Filters.

Following is a summary of the damage to these facilities.

INFLUENT CONDUIT

- Transverse cracks up to ½-in on concrete encasement
- Three joints in the ¼-inch thick steel cylinder separated
- Joint failed and opened up to ¾-inch at the soffit
- Fracture continued thru the top half of the joint
- Much spalling of the mortar lining about 8-inches on each side of the joint
- About 113-feet south of the 72-inch outlet, 75% of the joint failed
- Joint opened up about ¾-inch near the invert and the lining was damaged for about thirty inches each side of the joint
- Entire joint was pulled apart
- Mortar lining was damaged for about 24-inches on each side of the joint
- Considerable spalling and cracking of the lining was evident around the 72-inch outlet
- Lining suffered spalling and cracking approximately 15-feet downstream of the tunnel portal
- Several additional cracks, up to 1/16-inch wide, were observed in the lining
- Two 84-inch and 72-inch welded steel pipelines suffered only minor damage and consisted of cracking of the lining
- Minor cracking at the junction of the 72-inch pipelines and the 12-foot, 6-inch square reinforced concrete box conduit

- The 12-foot wide by 12-foot high reinforced concrete box extending northerly from the main control building had three transverse cracks in the walls and slabs located between Station 5+60 and 6+00;
- Cracks varied in width from 1/32-inch to 1/16 inch;
- 5 Transverse expansion joints in this portion of the influent conduit had separations varying from ½ -inch to 2-inches horizontally, and from ¼-inch to 1-inch vertically.

EFFLUENT CONDUIT

- Severe damage toward the southerly end;
- Differential displacement;
- Complete fracture or shearing.

MAIN CONTROL BUILDING

- Considerable horizontal and vertical displacement throughout; led to multiple non-structural damaged areas throughout building
- Building moved approximately 5-inches to the south and approximately 6-3/4-inches to the east
- There was settlement of 2-inches on the south side of the building causing a slight southeasterly tilt.

BALBOA INLET TUNNEL

- Concrete tunnel lining badly spalled and cracked at a distance approximately 100 feet near the Olive View Fault crossing;

CONNECTING CONDUITS

- Significant damage occurred at expansion joints, intersection of east-west and north-south galleries, and by punching of an embedded pipe into a wall
- Several portions of the structure between expansion joints moved as separated structures, on the three axes of movement, and also moved with twisting (torsional) action on each of the three planes
- In some cases, the joint filler and sealant was compressed and squeezed out of the joint
- Individual working of the structurally separated portions of the structure caused them to pound against each other, thereby resulting in spalling of concrete adjacent to the edges of the expansion joints
- Considerable cracking and some spalling occurred at the intersection of the east-west and north-south 25-foot wide influent conduit and pipe gallery, all were repairable
- Cracks in slabs and walls occurred at the intersection of pipe galleries Nos. 1 and 2 in the north-south influent conduit and pipe gallery, but all were repairable

- The southern end of the east-west pipe that was cast into the west wall of the north-south influent conduit pipe gallery pounded and caused the wall to shatter
- Large amount of movement took place in the overhead piping at the intersection of the east-west and north-south influent conduit pipe galleries
- Movement was in several directions, with pipe having been displaced.

MIXING AND SETTLING BASINS

- Significant damage occurred at expansion joints, and the intersection of the east-west and north-south galleries
- Several portions of the structure between expansion joints moved as separate structures on the three axes of movement
- Some cases, the joint filler and sealant was compressed and squeezed out of the joint;
- The individual working of the structurally separated portions of the structure caused them to pound against each other, thereby resulting in spalling of concrete adjacent to the edges of the expansion joint
- Cracking and some spalling occurred at the intersection of the east-west and north-south influent conduit and pipe gallery
- Cracks in slabs and walls occurred at the intersection of pipe galleries Nos. 1 and 2 in the north-south influent conduit and pipe gallery

FILTERS

- Some vertical and lateral displacement occurred between adjacent beds at some expansion joint locations
- Compressive loads forced expansion joint material out of some joints
- Minor spalling occurred adjacent to some expansion joints
- An apparent lateral thrust from the west caused the wash troughs to pull partly out of the insets
- Wash troughs acting as struts transferred the thrust to the gullet wall, which had not been completely poured, causing the wall to split at the east line of reinforcing bars
- Cracking and spalling in other filter beds occurred at the wash troughs but were minor in nature
- Minor spalling occurred where 16-inch spray header line passes through the wall filter beds
- The west end of the conduit was damaged
- Connection between the used washwater conduit and the 48-inch diameter conduit pulled apart
- Top walkway grid slab cracked diagonally across the northeast corner of filter bed
- Filter control building No. 2 separated from the walkway at the top of the filter beds expansion joint
- Separation varied from ½-inch to 1 ¼-inch at the expansion joint between Filter Control Building No. 2 and the valve and meter structure

- Valve and meter structure settled 1” lower than Filter Control Building No. 2
- Lining on north side of the return washwater line had a spalled area.

CHEMICAL BUILDING

- Severe lateral and vertical motion
- Column anchor bolts either stretched or pulled out of the footing concrete at all six columns
- Column in south wall buckled
- Column at northeast corner bowed out of line
- Diagonal bracing system in exterior walls failed
- Diagonals failed in tension or damaged in compression
- Upper concrete floors and roof were pierced by the diagonal bracing and columns
- Considerable cracking or spalling of slab concrete
- Building frame racked out of plumb, being tilted toward the east
- Metal door and window frames in north wall were racked out of square
- Several siding panels on the north wall broke loose from the framing
- Siding fasteners snapped off or pulled out
- All anchor bolts for the four chemical tanks failed by being sheared, bent or pulled out
- Tanks were not damaged by second floor slab; although marks on tank indicate that 6 to 8 inches of vertical movement took place
- Columns supporting exterior stairway were bent.

BRIDGE AND BOX CULVERT FOR RAILROAD SPUR TRACK

- Vertical crack at the juncture between the north abutment and the wing wall on the west side
- Wall and abutment became offset.

WASHWATER TANK

- Vertical movement of the tank
- Movement caused anchor bolts to either pull out or fail in tension
- Tank slammed down upon the ring wall, resulting in buckling in the upper courses of the tank skin
- Damage to stairway.

FINISHED WATER RESERVOIR

- North Wall:
    - Did not rupture but had 3 continuous horizontal cracks
    - Cracks varied in width from hairline to 1/32 inch and were spaced
    - There were many random vertical and diagonal hairline or large cracks.

- South Wall:
  - Easterly half of the south wall had several vertical and diagonal random cracks
  - Wall between column lines 'B' and 'C' was severely shattered
  - Some earth backfill entered the reservoir thru the wall and roof rupture
  - Random vertical and diagonal wall cracks occurred in the westerly half of the south wall
  - Fracturing and spalling occurred at other locations along the south wall on both the interior and exterior surfaces
  - Lateral offset at crack, particularly where it crossed the wall corbels.
- East Wall:
  - Portion of east wall, north of outlet received extensive damage
  - Bowed inward between the floor and roof slabs
  - Series of continuous horizontal cracks
  - Extensive lengths of spalls and cracks with some fractures occurred at the base of the wall
  - Large vertical crack occurred in the east wall
  - Overflow weir wall was also damaged and laterally offset at a vertical construction joint in the same area
  - East wall, south of the outlet structure, showed some offset and spalling at the floor line
  - Random and vertical cracks occurred at about mid-height
  - East wall of the finished water reservoir was severely fractured and spalled.
- West Wall:
  - Fractured and shattered above the floor slab line;
  - Horizontal displacement of the bottom of this wall occurred at the fracture;
  - Wall shattered for its full height between column 24 and 25.
- Roof
  - Failure plane occurred in the roof slab between column lines B and C
  - Extensive damage to the roof slab occurred adjacent to the drop panel connections;
  - Fracture at the drop panel line was apparent only in the north half of the reservoir
  - Continuous east-west failure occurred in line with the south edge of the roof slab drop panels
  - Roof slab south of this line had a vertical offset approximately 12 inches lower than the roof slab on the north side
  - From column line "0", east to column line "V", spalling was evident only at the west faces of the drop panels
  - Roof slab fractured between column lines "B" and "C"
  - Continuous east-west lines of failure occurred between column lines 3 and 4, 7 and 8, and 24 and 25. These breaks or spalls exposed the reinforcement for the full length of the reservoir roof slab.

- The width of spalling at the construction joint between column lines 24 and 25 varied between 4 feet and 6 feet. During the quake, this joint opened up, allowing for considerable quantities of gravel backfill to fall through from above.
- The roof slab was also severely spalled, shattered and offset vertically at the west edge of the drop panel line adjacent to the east wall
- Spalling also occurred at the west face of the drop panels at line "B" from column line 22, to a point midway between column lines 24 and 25.

RESERVOIR FLOOR

- While floor slab damage was general throughout the structure it was most apparent in the southeast quadrant
- Spalled strip running east-west between column 2 and 3, from a point midway between lines B and C to the east wall
- Spalled strip at the center of the structure, between lines 13 and 14. These spalled strips averaged about 2 feet wide and many of them had vertical offsets upward from the general floor level.
- There were additional spalled construction joints in the north-south direction; however, none of these were as long as the two east-west spalls previously described
- Spalling occurred at the drainage gutters for almost the entire length in both the north-south and east-west directions
- Continuous spalls occurred throughout and between various lines
- Floor cracking occurred midway between lines 14 and 15 in the east-west direction; the south exterior wall drop panels at M-1, N-1 and U-1 spalled in the east-west direction;
- Floor slab cracks located were located as follows:
  - North-south between lines Y and Z; from midway between lines 5 and 6 to a point midway between lines 17 and 18
  - North-south between lines between Z and AA, from a point midway between lines 2 and 3 to a point midway between lines 19 and 20; diagonally across the southeast corner of drop panel W-18
  - North-south between lines P and Q; from a point midway between lines 13 and 14; to column line 15
  - East-west between lines 14 and 15, from a point midway between lines D and E, to a point midway between lines E and F.

BAFFLE WALLS AND COLUMNS

- Damage to the baffle walls consisted of two principal types; cracking or fracturing of the vertical beams and dislodgement and fracturing of the corrugated asbestos cement panels, only one vertical concrete beam collapsed
- The other beams remained standing but were tilted out of plumb
- Many of the other vertical beams were fractured or cracked near the base or in the region slightly above the base
- There were a number of spalls in the cast-in-place concrete projections forming the panel slots on the sides of the circular roof columns
- A large number of the corrugated asbestos cement panels were damaged or completely destroyed. Some of them fell to the floor and were shattered, while others that remained in place were damaged less severely.
- Approximately 73 baffle walls vertical beams sustained cracks, fractures, spilling, etc.
- Damage to the reservoir roof columns varied widely, from hairline cracks to complete fractures
- The damage to any individual column appeared generally to be the same at the top as at the bottom
- The majority of columns were spalled, or otherwise damaged on the east and west sides
- There were two notable exceptions: The first row of columns south of the north wall and the first row of columns north of the south. In these two rows, major damage occurred on the north and south sides
- In all cases, damage to the circular columns appeared to be primarily due to flexure and not to vertical load
- A number of the columns, notably those in the first row east of the west wall, were visibly out of plumb
- The tops of these columns were displaced east. Damage to drop panels and column capitals were generally limited to minor spalls and some cracks, except for several bottom capitals located in the northeasterly quadrant of the reservoir that were fractured or shattered.

RESERVOIR OUTLET STRUCTURE

- Severe and extensive damage;
- Fractures throughout the entire structure.

RESERVOIR INLET STRUCTURE

- Moderate damage;
- Spalled concrete exposing reinforcement.

1994 NORTHRIDGE EARTHQUAKE

In 1994, the Northridge earthquake occurred on January 17, at 4:30 a.m. It had a duration of approximately 10–20 seconds. The blind thrust earthquake had a moment magnitude (M_w) of 6.7. The death toll was 57, with more than 8,700 injured. In addition, property damage was estimated to be between $13 and $50 billion, making it one of the costliest natural disasters in U.S. history. LADWP reported a total of 1,405 pipe repairs and that water pressure had dropped to zero in some areas. The epicenter was approximately 7.3 miles from the Jensen Plant.

Metropolitan had damage at the Jensen Plant and adjacent facilities. Following is a summary of the damage to these facilities:

MAJOR DAMAGE

- Jensen Plant Balboa Influent Conduit
  - 84-in influent pipeline severed approximately 3-in horizontally and 1-in vertically near venturi structure
- East Valley Feeder
  - Pipeline breaks occurred between Odessa and Rinaldi Streets (976+86.70) and Woodley Avenue and Rinaldi Street (957+66.50)
  - Sectionalizing valve damage caused damage to all electrical equipment
  - Street asphalt damage as result of pipe breaks/leaks
- West Valley Feeder No. 1
  - Crack at cut-off wall at Station 1219+10
  - Sectionalizing valve structure damaged, causing damage to all electrical equipment
- Main Electrical Center
- Service Connection CLWA-1T
  - Service connection structure settled and drifted laterally
  - Misalignment of valve assemblies
- Service Connection LA-25
  - Extensive damage at ten pipe joints in the 97-in diameter pipeline and 60-in diameter overflow pipeline; pipe joints spread 1/8” to 3/4”
  - Reinforced box conduit suffered a break and 2” separation; a 6-1/2” separation occurred at the joint where the double box conduit meets the discharge structure
  - Turnout structure moved 6 to 8 inches east
  - Double box conduit moved 3 inches to the east

- Service Connection LA-35T
  - Damage to valve structure and pipe bridge due to differential displacement
- Newhall Tunnel
  - Buckling of steel liner
  - Concrete construction joints opened and closed resulting in sand and water infiltration
  - Bulge on steel liner split at circumferential joint resulting in oil and water infiltration

Appendix 5

Metropolitan Water Storage Capacity

This page intentionally blank.

Over the past two decades, Metropolitan has developed a large regional storage portfolio that includes both dry year and emergency storage capacity. Storage generally takes two forms: surface reservoirs and groundwater basin storage. Heading into the most recent drought cycle, Metropolitan had developed over 5.5 million acre-feet of storage capacity and had successfully stored over 2.7 million acre-feet. This is a more than 13 times the storage capacity compared to the 1980s, with record quantities of water in reserve. This increase in storage capacity is shown in Figure 5-1.

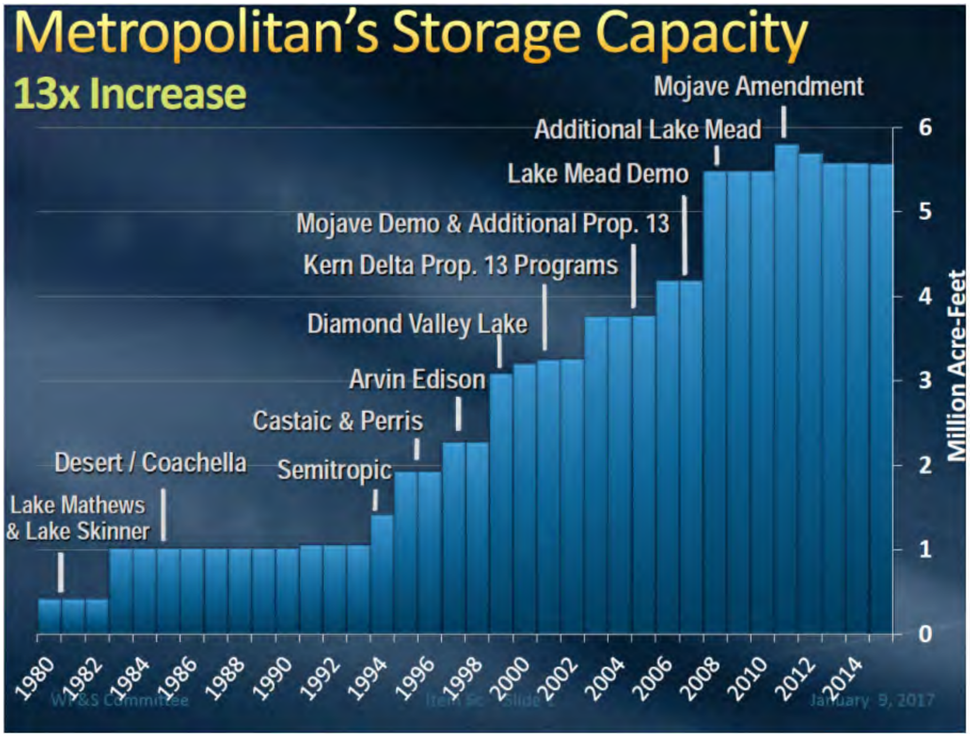

Figure 5-1. Summary of Metropolitan's Storage Capacity Over Time

Some examples of storage resources that have been developed since 1990 include:

- Surface Water Reservoirs:
  - Diamond Valley Lake (810,000 acre-feet)
  - SWP Article 56 Carryover Storage (up to 200,000 acre-feet)
  - Flexible Storage in Castaic Lake and Lake Perris (219,000 acre-feet)
  - Intentionally Created Surplus in Lake Mead (1.5 million acre-feet)
- Groundwater Storage:
  - Member Agency Conjunctive Use Programs (210,000 acre-feet)
  - Semitropic Storage Program (350,000 acre-feet)
  - Arvin-Edison Storage Program (350,000 acre-feet)
  - San Bernardino Municipal Water District Storage Program (50,000 acre-feet)
  - Kern Delta Water District Storage Program (250,000 acre-feet)
  - Mojave Storage Program (390,000 acre-feet)

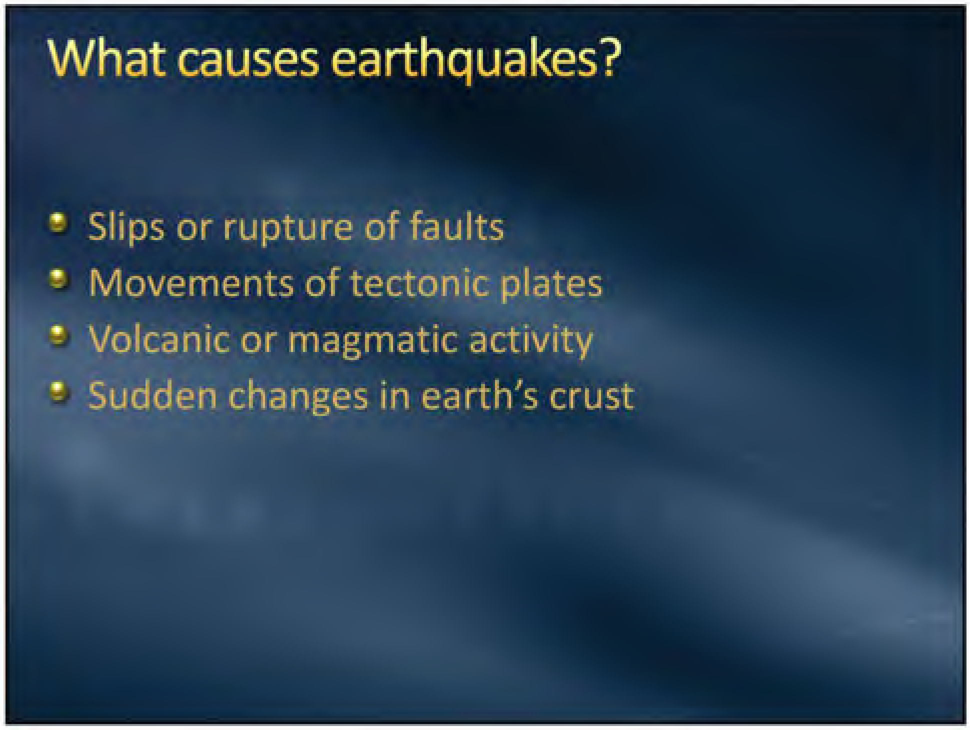
Seismic Design FAQs

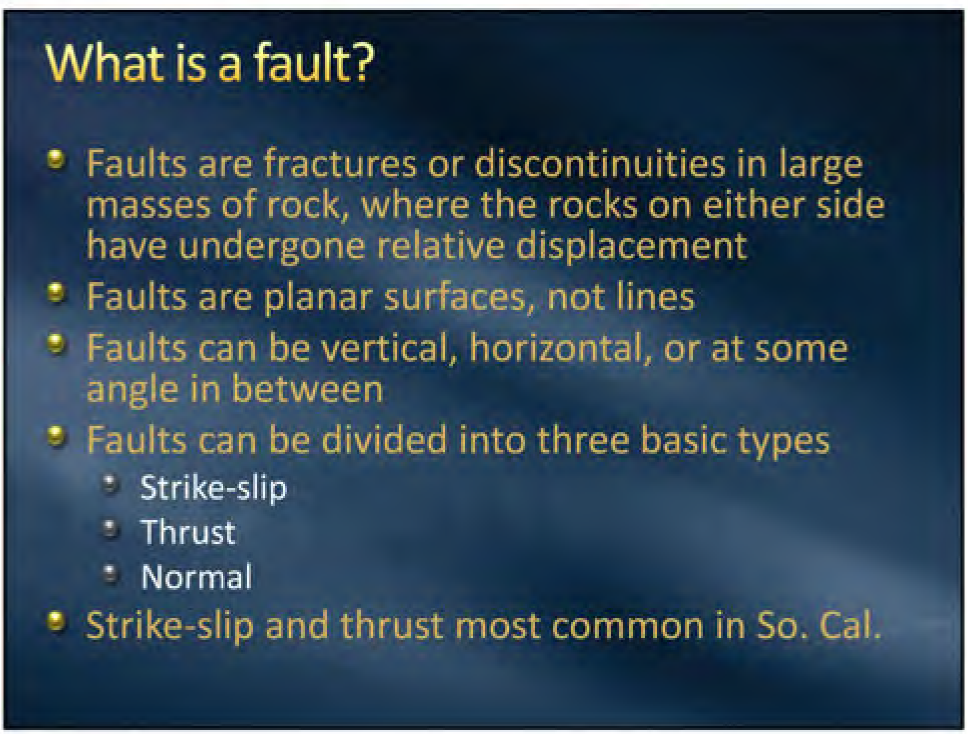
September 2017

What are the effects of earthquakes?

- Ground shaking
- Ground rupture
- Liquefaction
- Landslides and avalanches
- Tsunamis



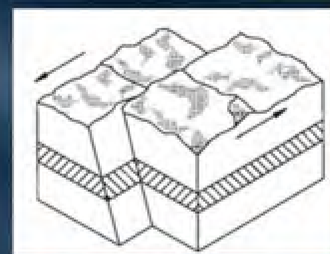
What causes earthquakes?
Slips or rupture of faults
Movements of tectonic plates
Volcanic or magmatic activity
Sudden changes in earth's crust



What is a fault?
Faults are fractures or discontinuities in large masses of rock, where the rocks on either side have undergone relative displacement
Faults are planar surfaces, not lines
Faults can be vertical, horizontal, or at some angle in between
Faults can be divided into three basic types
Strike-slip
Thrust
Normal
Strike-slip and thrust most common in So. Cal.

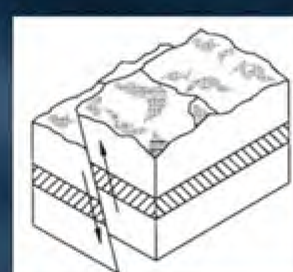
Strike-Slip Faults

- Faults are primarily vertical or near-vertical
- Movement occurs primarily laterally - one side slides by the other
- Primary examples are the San Andreas and San Jacinto Faults



Thrust Faults

- Faults occur at an angle to the surface
- Movement occurs primarily vertically - one side slides up over the other
- Primary examples are the Santa Susana and Bunker Hill Faults



Major Earthquake Faults in So. Cal.

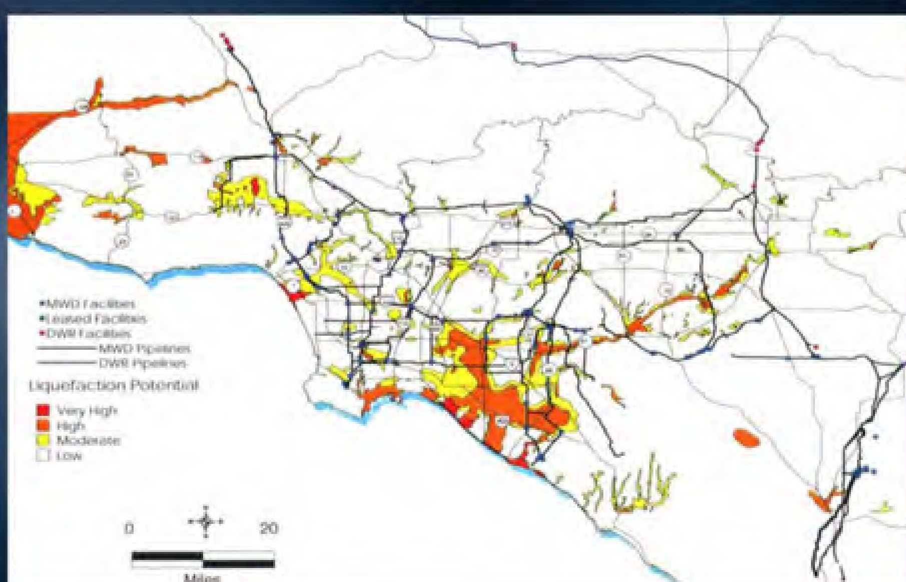
San Andreas Fault

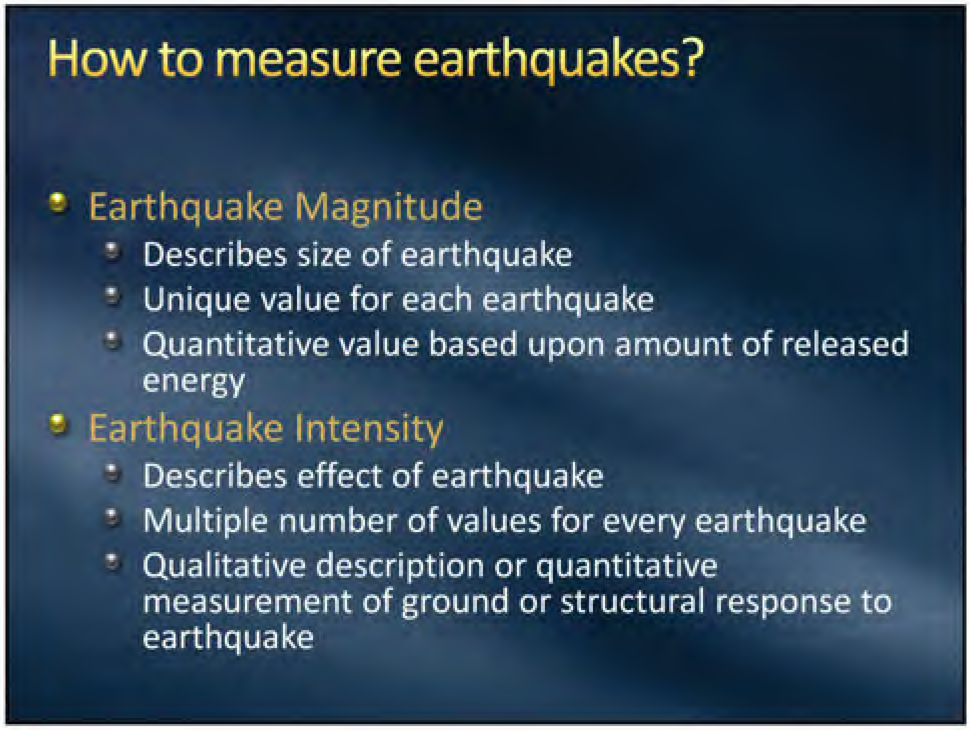
- Fault with the highest probability of generating a major earthquake in So. Cal.
- Potential impact on MWD operation
  - CRA
  - Hinds and Eagle Mountain Pumping Plants
  - Rialto and Inland Feeders
  - East Branch of State Water Project
  - DWR's Santa Ana Pipeline

Liquefaction

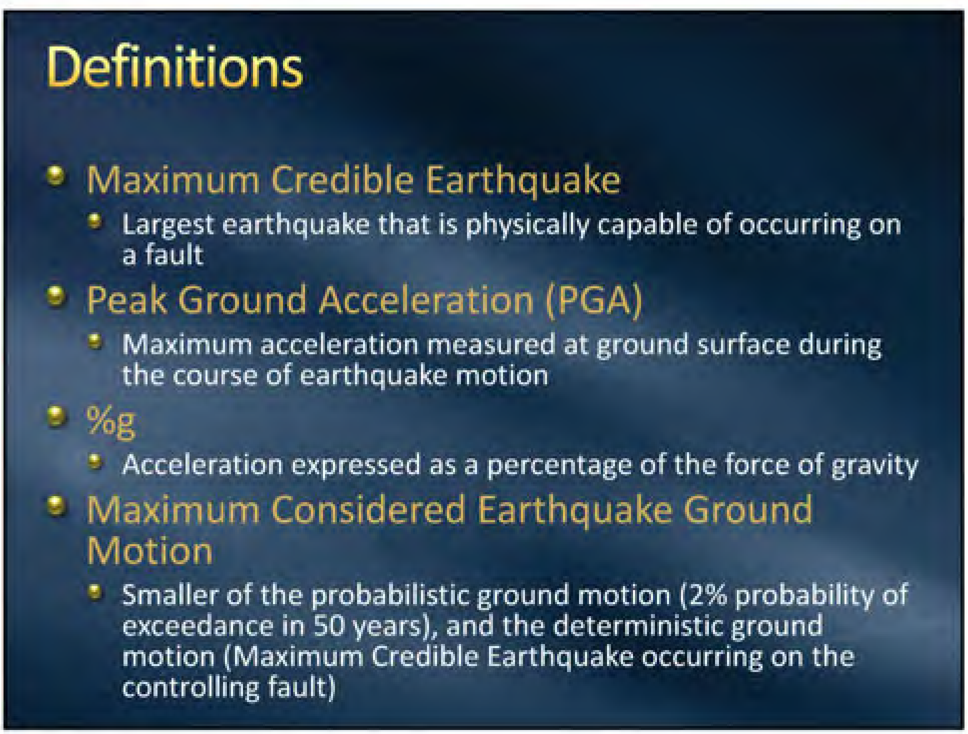
- What is liquefaction?
  - A process by which water-saturated soils temporarily lose strength and act like liquid
- Factors needed for liquefaction
  - Loose or low density sandy soils
  - Shallow ground water
  - Strong ground shaking

Liquefaction Susceptible Zones in So. Cal.

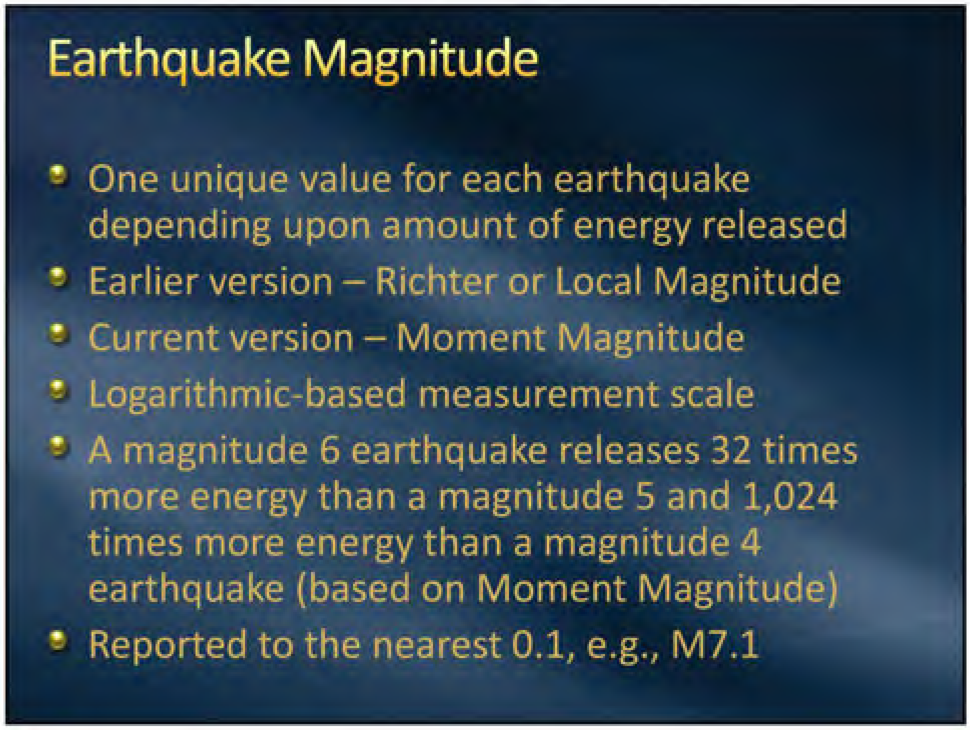




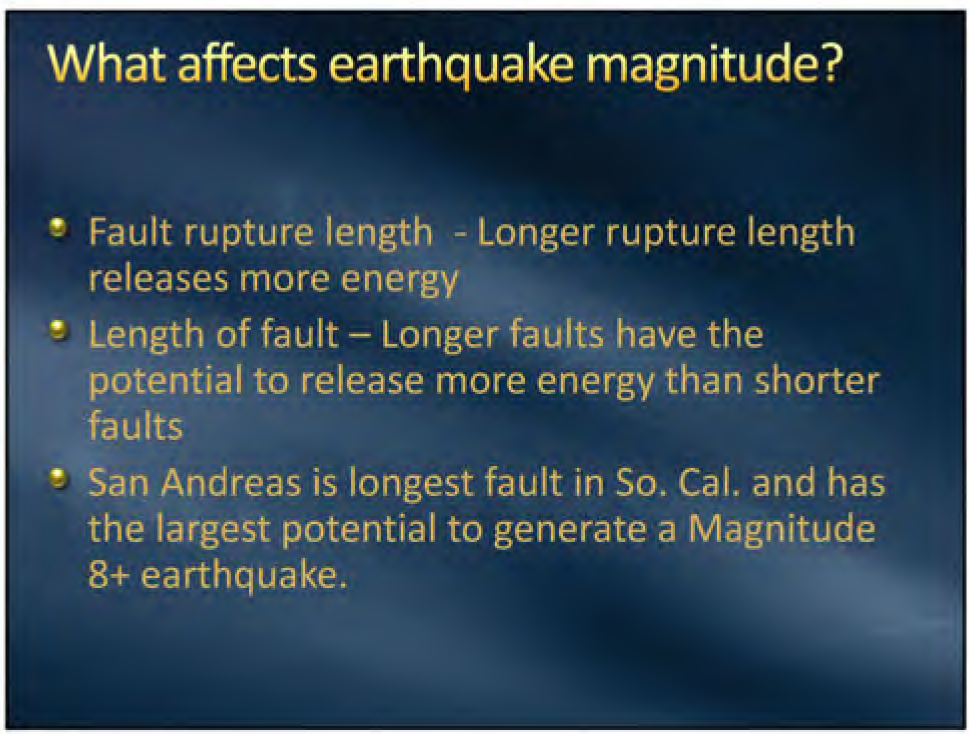
How to measure earthquakes?
Earthquake Magnitude
Describes size of earthquake
Unique value for each earthquake
Quantitative value based upon amount of released energy
Earthquake Intensity
Describes effect of earthquake
Multiple number of values for every earthquake
Qualitative description or quantitative measurement of ground or structural response to earthquake



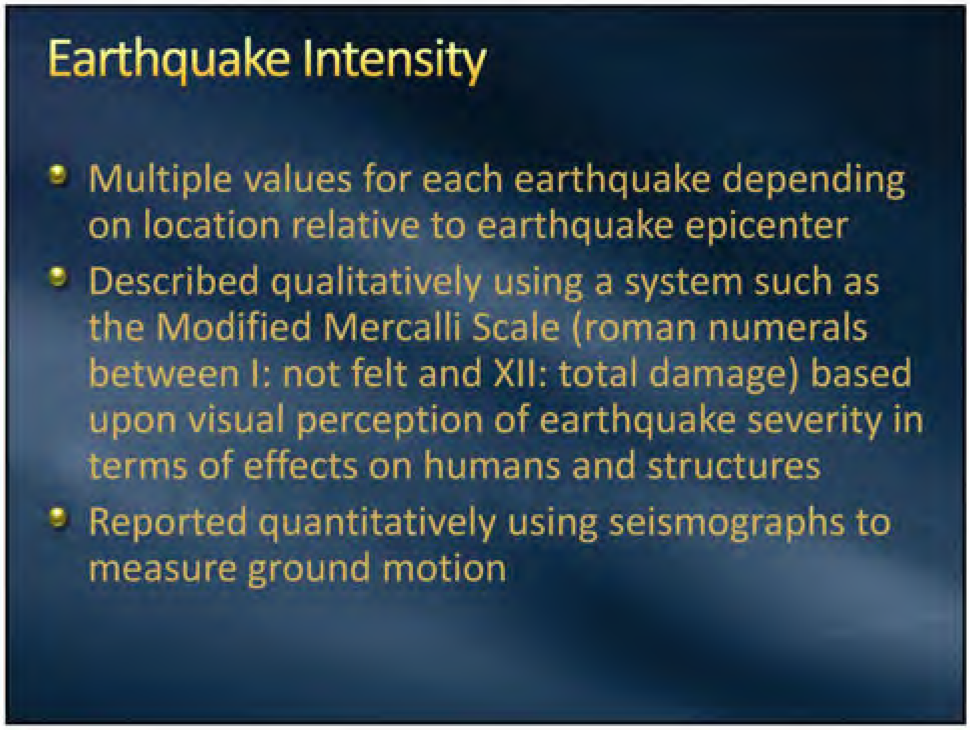
Definitions
Maximum Credible Earthquake
Largest earthquake that is physically capable of occurring on a fault
Peak Ground Acceleration (PGA)
Maximum acceleration measured at ground surface during the course of earthquake motion
%g
Acceleration expressed as a percentage of the force of gravity
Maximum Considered Earthquake Ground Motion
Smaller of the probabilistic ground motion (2% probability of exceedance in 50 years), and the deterministic ground motion (Maximum Credible Earthquake occurring on the controlling fault)



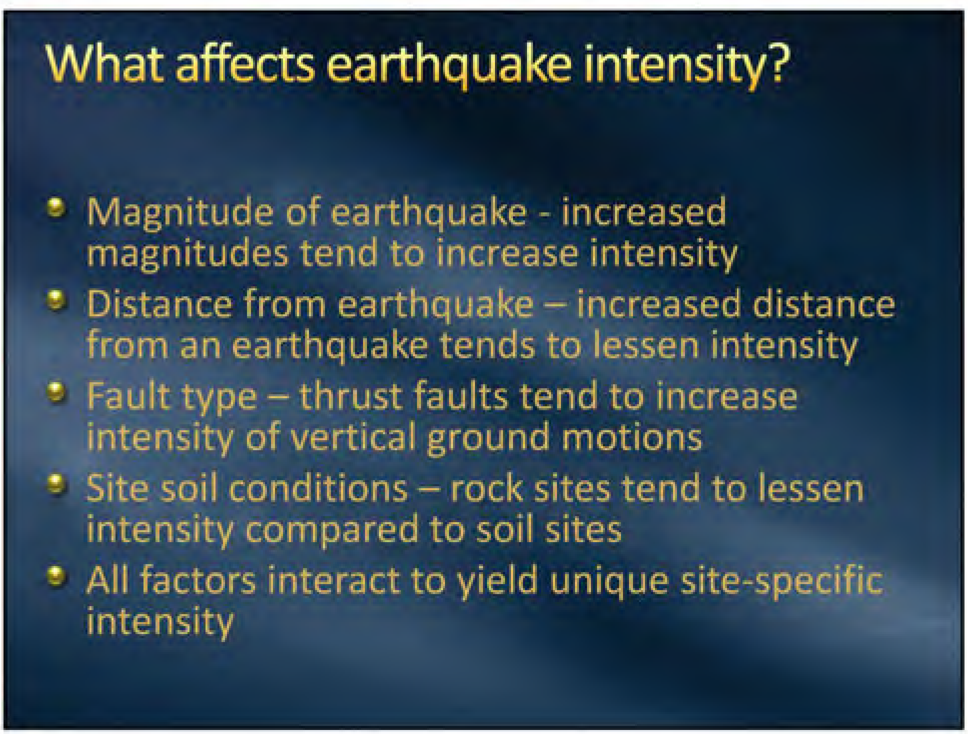
Earthquake Magnitude
One unique value for each earthquake depending upon amount of energy released
Earlier version – Richter or Local Magnitude
Current version – Moment Magnitude
Logarithmic-based measurement scale
A magnitude 6 earthquake releases 32 times more energy than a magnitude 5 and 1,024 times more energy than a magnitude 4 earthquake (based on Moment Magnitude)
Reported to the nearest 0.1, e.g., M7.1



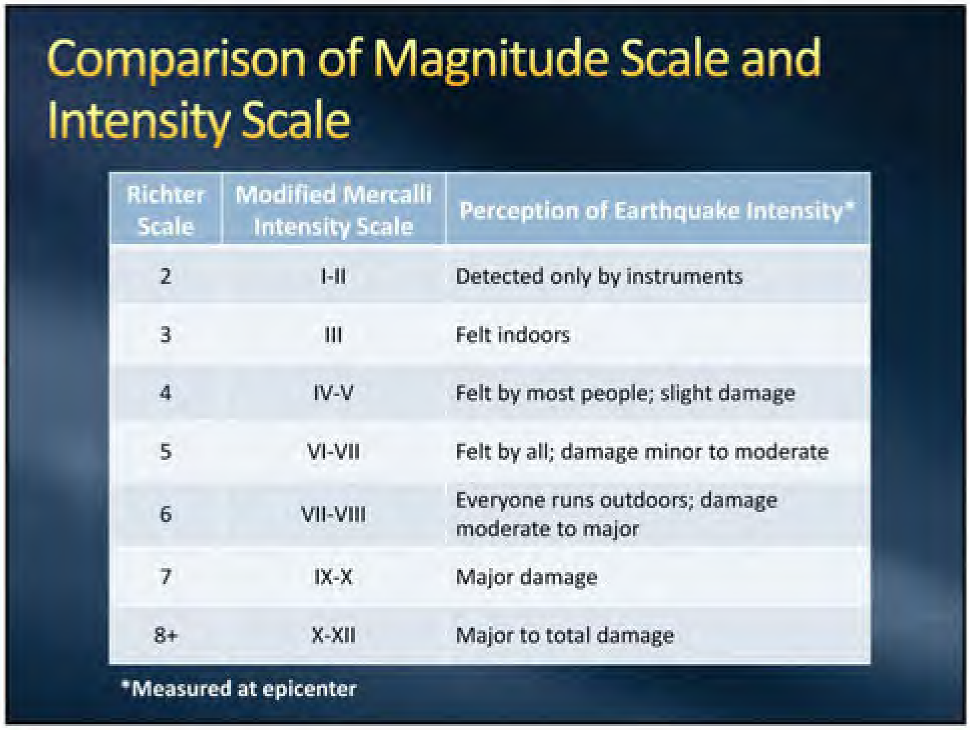
What affects earthquake magnitude?
Fault rupture length - Longer rupture length releases more energy
Length of fault – Longer faults have the potential to release more energy than shorter faults
San Andreas is longest fault in So. Cal. and has the largest potential to generate a Magnitude 8+ earthquake.



Earthquake Intensity
Multiple values for each earthquake depending on location relative to earthquake epicenter
Described qualitatively using a system such as the Modified Mercalli Scale (roman numerals between I: not felt and XII: total damage) based upon visual perception of earthquake severity in terms of effects on humans and structures
Reported quantitatively using seismographs to measure ground motion



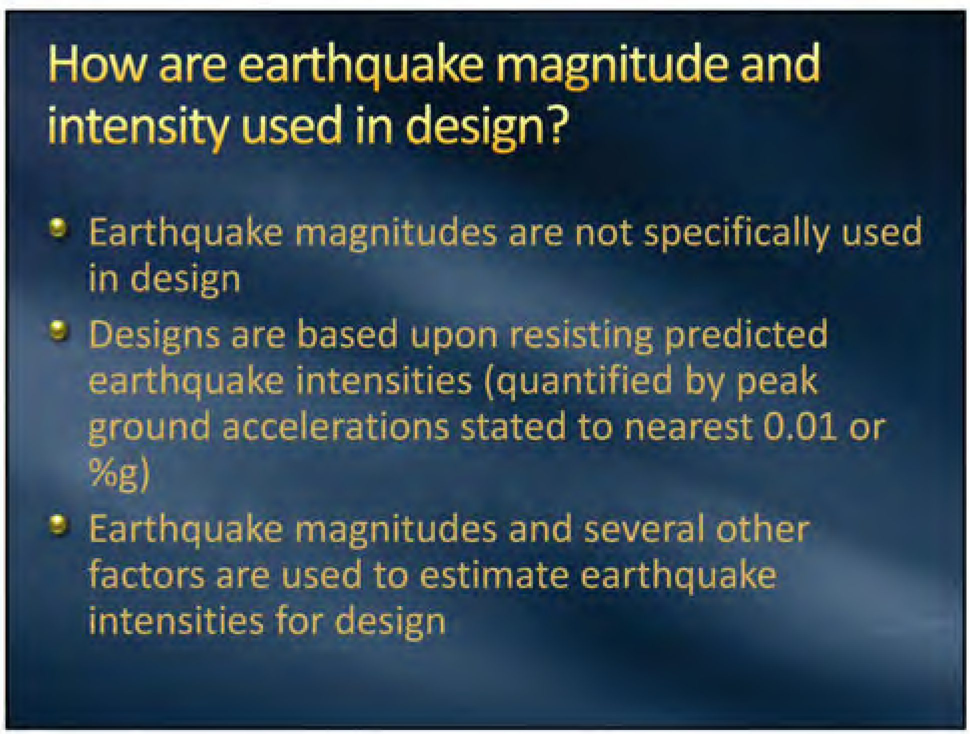
What affects earthquake intensity?
Magnitude of earthquake - increased magnitudes tend to increase intensity
Distance from earthquake – increased distance from an earthquake tends to lessen intensity
Fault type – thrust faults tend to increase intensity of vertical ground motions
Site soil conditions – rock sites tend to lessen intensity compared to soil sites
All factors interact to yield unique site-specific intensity



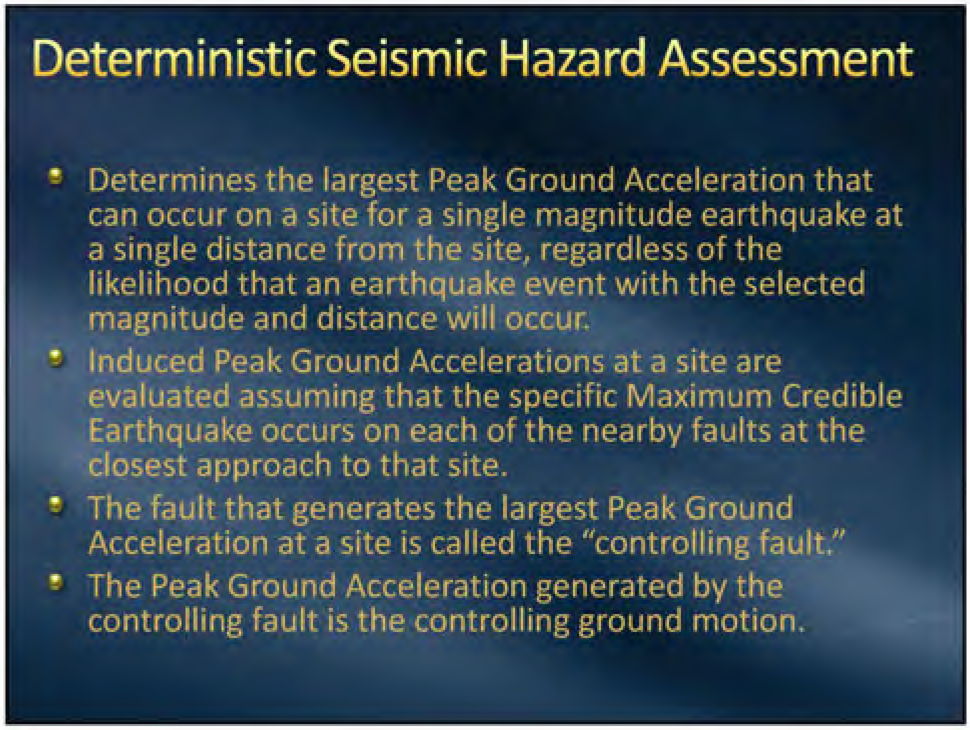
Comparison of Magnitude Scale and Intensity Scale

Richter Scale	Modified Mercalli Intensity Scale	Perception of Earthquake Intensity*
2	I-II	Detected only by instruments
3	III	Felt indoors
4	IV-V	Felt by most people; slight damage
5	VI-VII	Felt by all; damage minor to moderate
6	VII-VIII	Everyone runs outdoors; damage moderate to major
7	IX-X	Major damage
8+	X-XII	Major to total damage

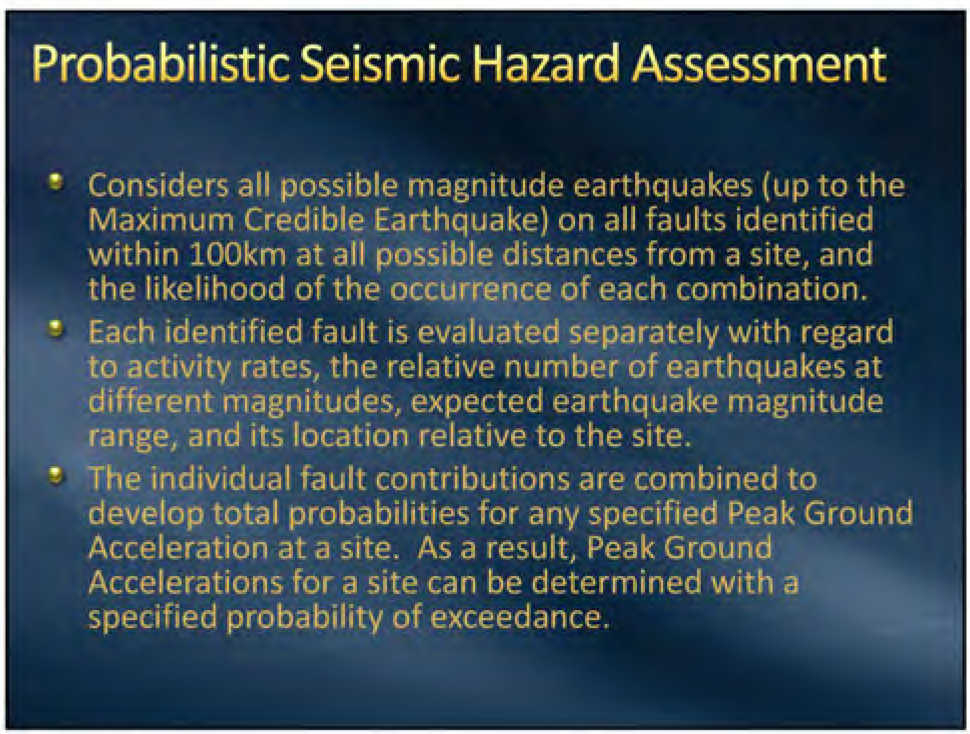
*Measured at epicenter



How are earthquake magnitude and intensity used in design?
Earthquake magnitudes are not specifically used in design
Designs are based upon resisting predicted earthquake intensities (quantified by peak ground accelerations stated to nearest 0.01 or %g)
Earthquake magnitudes and several other factors are used to estimate earthquake intensities for design



Deterministic Seismic Hazard Assessment
Determines the largest Peak Ground Acceleration that can occur on a site for a single magnitude earthquake at a single distance from the site, regardless of the likelihood that an earthquake event with the selected magnitude and distance will occur.
Induced Peak Ground Accelerations at a site are evaluated assuming that the specific Maximum Credible Earthquake occurs on each of the nearby faults at the closest approach to that site.
The fault that generates the largest Peak Ground Acceleration at a site is called the "controlling fault."
The Peak Ground Acceleration generated by the controlling fault is the controlling ground motion.



Probabilistic Seismic Hazard Assessment
Considers all possible magnitude earthquakes (up to the Maximum Credible Earthquake) on all faults identified within 100km at all possible distances from a site, and the likelihood of the occurrence of each combination.
Each identified fault is evaluated separately with regard to activity rates, the relative number of earthquakes at different magnitudes, expected earthquake magnitude range, and its location relative to the site.
The individual fault contributions are combined to develop total probabilities for any specified Peak Ground Acceleration at a site. As a result, Peak Ground Accelerations for a site can be determined with a specified probability of exceedance.

Current Building Code Seismic Design Requirements

- Maximum Considered Earthquake (MCE) Ground Motion
  - Probabilistic: Ground motion with 2% probability of exceedance in 50 years
  - Deterministic: Ground motion generated by Maximum Credible Earthquake occurring on the controlling fault(s)
  - Smaller ground motion determined by these two methods governs design
  - Deterministic approach usually governs in So. Cal.
- A Regular Facility is designed for 2/3 of MCE Ground Motion to achieve Life Safety performance
- An Essential Facility is design for a higher performance
  - Building codes establish the minimum seismic design criteria, and building owners can choose to design for a higher performance
- Building codes do not apply to facilities under Cal. Division of Safety of Dams (DSOD) jurisdiction

Examples of Regular and Essential Facilities

Facilities	Description	Examples
Regular	Normal occupancy	•Commercial buildings •Residential buildings •Manufacturing facilities
Essential	High occupancy/Special occupancy	•Schools •Hospitals •Jails, detention facilities •Public utility facilities •Hazardous material storage facilities • Fire and police stations • Emergency shelters • Aviation facilities

Based on IBC 2009, ASCE 7-05

Examples of Design Peak Ground Acceleration in Recent Codes

Codes	Year in Effect in Cal.	Design Peak Ground Acceleration (PGA)[+]		
		Weymouth	USHQ	Skinner
UBC 1994	1995	0.4g	0.4g	0.4g
1994 Northridge Earthquake - Resulted in codification of the near-source effect*				
UBC 1997	1998	0.52g	0.4g	0.4g
Seismic hazard map updated to reflect the adoption of Maximum Considered Earthquake Ground Motion as the basis of structural design				
IBC 2009	2010	0.71g	0.59g	0.4g

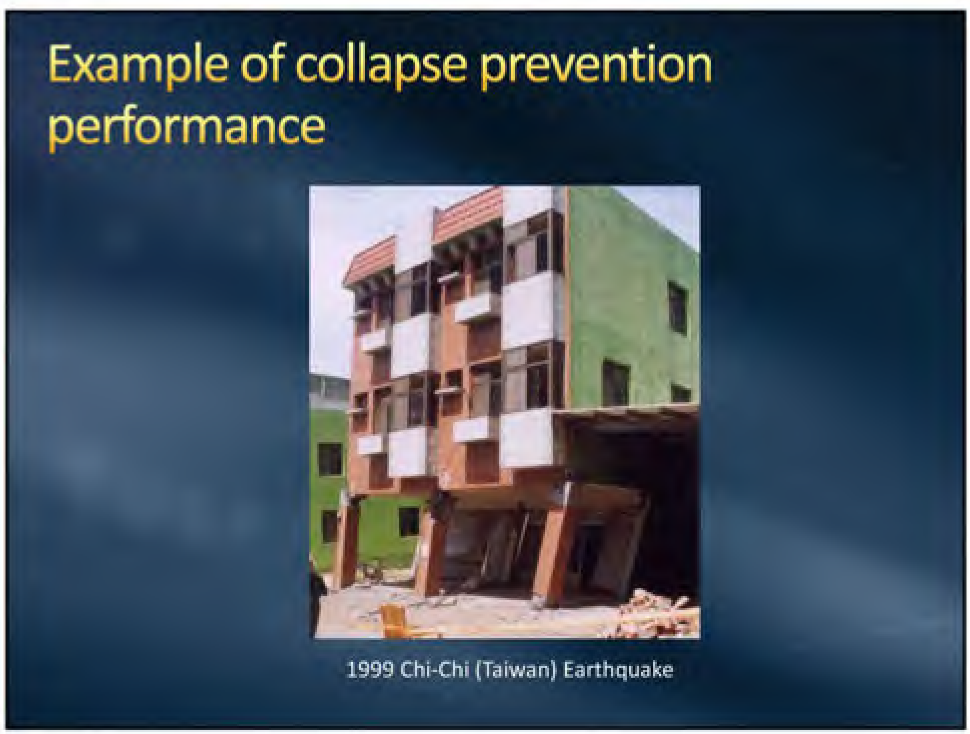
[+]The listed PGA values are based on generic seismic hazard maps included in the codes. A site-specific analysis may result in different values.
*Other factors such as frequency contents and shaking duration will result in adverse effect on structures that cannot be captured by PGA along. The effect is more pronounced when the site is close to earthquake epicenter, and accounted for by amplifying PGA.

How to define seismic performance of structures?

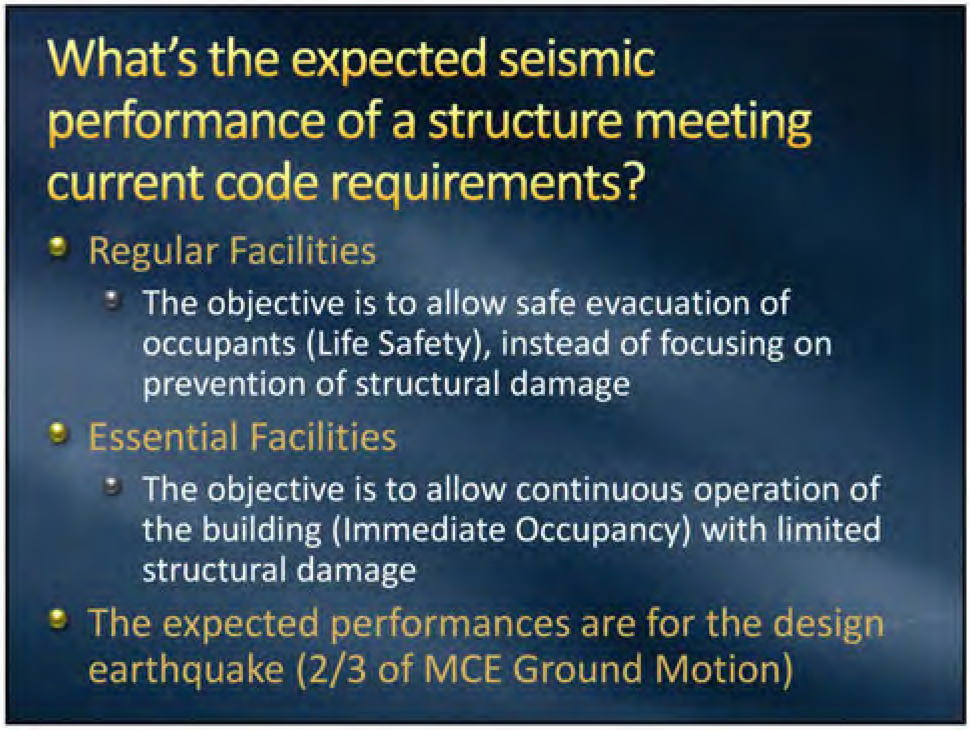
Structural Performance Level*	Expected Performance	Post-Earthquake Assessment
Immediate Occupancy	• Limited structural damage • Safe to occupy immediately after earthquake with minor repair	Green
Life Safety	• Significant structural damage; no imminent risk of collapse • Occupants would safely evacuate from the building • Not safe to occupy w/o major repair. Repair may be economically impractical.	Yellow or Red
Collapse Prevention	• Extensive structural damage and on verge of partial or total collapse • Building is likely damaged beyond repair both technically and economically	Red

*As defined in ASCE 41-06 Seismic Rehabilitation of Existing Buildings

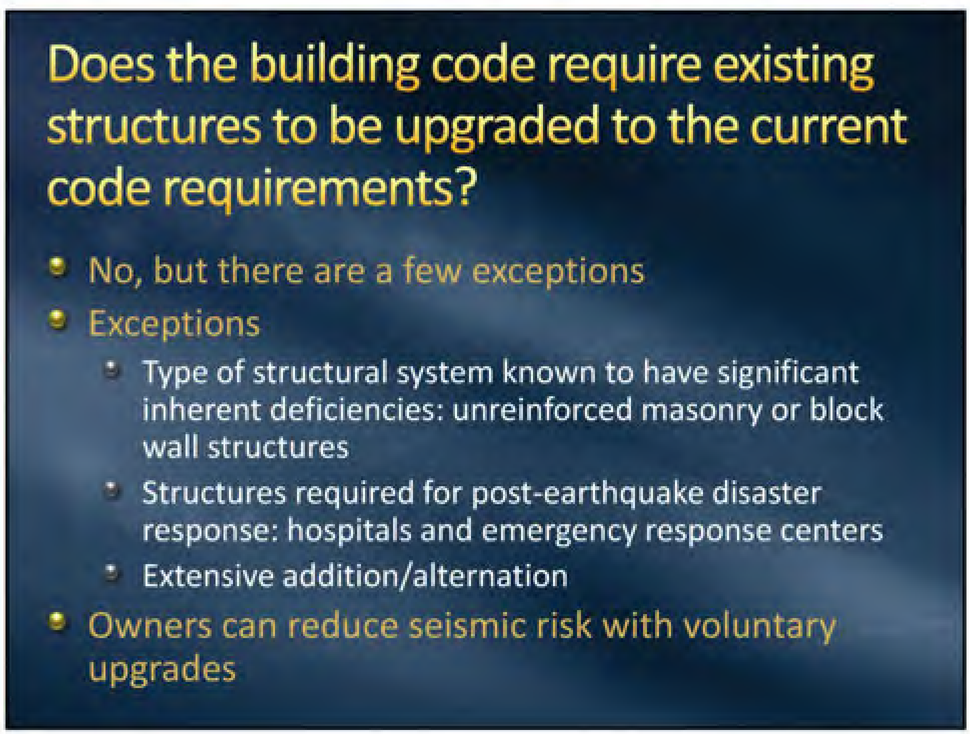
Example of life safety performance
1999 Chi-Chi (Taiwan) Earthquake



Example of collapse prevention performance
1999 Chi-Chi (Taiwan) Earthquake



What's the expected seismic performance of a structure meeting current code requirements?
Regular Facilities
The objective is to allow safe evacuation of occupants (Life Safety), instead of focusing on prevention of structural damage
Essential Facilities
The objective is to allow continuous operation of the building (Immediate Occupancy) with limited structural damage
The expected performances are for the design earthquake (2/3 of MCE Ground Motion)



Does the building code require existing structures to be upgraded to the current code requirements?
No, but there are a few exceptions
Exceptions
Type of structural system known to have significant inherent deficiencies: unreinforced masonry or block wall structures
Structures required for post-earthquake disaster response: hospitals and emergency response centers
Extensive addition/alternation
Owners can reduce seismic risk with voluntary upgrades

What's the acceptable seismic performance level for an existing structure, as it may not meet the current code requirements?

- Depending on post-earthquake functions of the building, the owner may choose the desired performance level
  - Immediate Occupancy
  - Life Safety
  - Collapse Prevention
- Non-building structures (reservoirs, tanks...) are designed based on consensus standards and guidelines (e.g. ASCE, ASME, AWWA...)
  - Operational
  - Prevention of uncontrolled release of contents

What seismic performance are specified in MWD's seismic design criteria?

Building Type Structures				
Importance Designation	**Essential Facilities**		**Regular Facilities**	
	New	**Existing**	**New**	**Existing**
Building Code and Industry Standards	CBC ASCE 7	CBC ASCE 41	CBC ASCE 7	CBC ASCE 41
Design Intent Per Code/ Standard Language	Provide a larger margin against collapse in MCE and remain operational in Design Earthquake (2/3 MCE)	Enhanced performance against life safety in Design Earthquake	Collapse prevention in MCE and prevent life threatening damage in Design Earthquake	To achieve life safety in Design Earthquake
Metropolitan Seismic Design Objective	To remain operational following a major seismic event	Intended to maintain occupancy immediately following a major seismic event	May experience significant damage, but would prevent life threatening injury or casualty following a major seismic event	May experience significant damage, but would prevent life threatening injury or casualty following a major seismic event

What seismic performance are specified in MWD's seismic design criteria? (Cont.)

Water Containing Structures				
Importance Designation	**Essential Facilities (Related to Water Delivery)**		**Regular Facilities (Not Related to Water Delivery)**	
	New	**Existing**	**New**	**Existing**
Building Code and Industry Standards	CBC ASCE 7 ACI350 AWWA D100 API 650	CBC ASCE 41 ACI350 AWWA D100 API 650	CBC ASCE 7 ACI350 AWWA D100 API 650	CBC ASCE 41 ACI350 AWWA D100 API 650
Design Intent Per Code/ Standard Language	Provide a larger margin against failure in MCE and require a higher level of liquid tightness to maintain serviceability in Design Earthquake (2/3 MCE)	Not differentiated.	Prevent catastrophic failure in MCE and prevent uncontrolled release of liquid in Design Earthquake	Not differentiated.
Metropolitan Seismic Design Objective	To remain operational following a major seismic event	To remain operational or can be restored quickly following a major seismic event	May experience significant leak and require dewatering to repair, but would prevent uncontrolled release of liquid following a major seismic event	May experience significant leak and require dewatering to repair, but would prevent uncontrolled release of liquid following a major seismic event

How do the design and performance for a new facility and retrofit of an existing facility compare?

Appendix 7

Summary of Previous Metropolitan Seismically Induced Damage Studies

This page intentionally blank.

The impact of earthquakes on Southern California and on Metropolitan's system has been the subject of several previous internal and external assessments:

Seismic Risk Assessment of Local Water Production Facilities in the Service Area of Metropolitan Water District of Southern California, **January 14, 1991, Dames & Moore.** This is a comprehensive report on the effects of a major earthquake on the Southern San Andreas Fault. The report has various models for estimating damage and concludes that there could be hundreds of local water pipelines damaged, loss of power, etc. Metropolitan feeders that are vulnerable to damage were identified, and the report estimates that Metropolitan service will be lost for 6 months or less. The report also predicts significant damage to ground water wells.

***Probable Maximum Loss Analysis for Metropolitan Water District of Southern California*. September 1998, EQE International.** This report was prepared to assess the potential monetary loss associated with several earthquake scenarios. This report highlighted the potential for widespread damage resulting from an earthquake. The study did not address the impact on deliveries or system recovery.

Assessment of Frequency of Recovery Plan and Extreme Events within the Metropolitan Water District Service Area, **December 2001, Geomatrix Consultants.** This report was prepared to aid in the evaluation of hazards under the System Reliability Plan (see next report). This report evaluated the probability of earthquakes of two levels of severity within Metropolitan's service area. The first was a moderate (strong) earthquake similar to the Northridge earthquake (M6.7) and the second was an extreme event, on the order of M7.5. The report provided information on the probability of these earthquakes both within each of Metropolitan's operating regions and within the service area as a whole. The scope of the report did not include evaluating the impact on service or time for recovery.

Distribution System Reliability Assessment, (Report No. 1227), **December 2006, Metropolitan Facility Planning staff.** This report evaluated the reliability of the distribution system. In addition, a separate section of the report dealt with the vulnerability of Metropolitan's facilities to various initiating events. The report addressed the probability of failures in the system due to various random causes including earthquakes. It utilized information from the Geomatrix study to estimate the probability of seismically induced failures. Estimates for the recovery time from the various events were provided.

Facility Reliability Assessments, **2006, Metropolitan Facility Planning staff.** Reliability assessments were conducted by Metropolitan of the five treatment plants and the Colorado River Aqueduct. These assessments evaluated the susceptibility of individual facilities to a series of hazards such as fire, flooding, and earthquakes. Earthquakes were identified as one of the highest risk hazards because of the potential to cause numerous simultaneous failures. The reliability assessments identified structures that had not been updated to the latest seismic criteria. As part of the Seismic Upgrade Program, these structures have been evaluated. Where necessary, capital projects were initiated to upgrade the facilities to the most recent building codes. Completed Facility Reliability Assessments are listed below:

- *Diemer Water Treatment Plant Reliability Assessment, (Report No. 1225),* 2006
- *Skinner Water Treatment Plant Reliability Assessment, (Report No. 1246),* 2006
- *Weymouth Water Treatment Plant Reliability Assessment, (Report No. 1255),* 2006

- *Mills Water Treatment Plant Reliability Assessment, Report No. 1269,* 2006
- *Jensen Water Treatment Plant Reliability Assessment, Report No. 1280,* 2006
- *Colorado River Aqueduct Reliability Assessment, Report No. 1297,* 2006

***System Reliability Study,* 2007, Metropolitan Facility Planning staff.** This study evaluated the reliability of the entire system. This study examined the impact of single failures within the system on the ability to deliver water to member agencies and identified existing backup options. The failures considered included individual facilities as a unit (e.g., a treatment plant or a reservoir). For pipelines, the study considered a failure in each isolatable segment of the line. The impact on deliveries to each service connection was identified and over 250 different events were studied. The study considered capabilities within Metropolitan's system, as well as the member agencies', to mitigate the failures. This study did not consider multiple failures that might be associated with an earthquake due to the almost unlimited number of combinations of failures that would have to be considered.

Golden Guardian 2008. In November 2008, under the auspices of the USGS, Caltech and Earthquake Research Associates, a major disaster drill was conducted in Southern California. The drill was based on a magnitude 7.8 earthquake on the San Andreas Fault (Golden Guardian Exercise). The preliminary studies conducted as part of the exercise indicated that major damage is expected. The impact on water systems was one of the areas of focus for the drill and the related studies. The studies concluded that in areas impacted heavily, water service could be lost for six months.

***Potential Effects of Southern California Seismic Events on Metropolitan Water Deliveries (Report No. 1335)*, January 2009, Metropolitan Facility Planning staff.** This report provided a perspective on the magnitude of damage that could result from moderate and extreme earthquakes, the corresponding potential impacts on Metropolitan water deliveries, and estimated time frames for restoring service. The report also offered recommendations for reducing the potential impacts of certain significant seismic events.

***Mills Water Supply Reliability Study (Report No. 1337),* Metropolitan Facility Planning staff.** The Mills study was prepared in response to findings of the Integrated Area Study, which identified risks to the raw water supply to the Mills plant. The study evaluated alternatives to improve the reliability and redundancy of the raw water supply to Mills. A capital project has been initiated to implement one of the options.

***Potential Impact of a Seismic Event on the CRA Tunnels (Report No.* 1478), August 2014, Metropolitan Facility Planning staff.** This is the first report of a comprehensive study of the seismic vulnerability of the CRA. Five companion reports (Metropolitan Report Numbers 1470, 1484, 1485, 1490 1558) are described below. This study evaluated the vulnerability of CRA tunnels to damage from a major seismic event, provided a perspective of the level, extent and type of seismic damage that could be imposed on CRA tunnels, and estimated the time frame to restore service. The results of the study showed that most of the CRA tunnels are expected to perform well following a large seismic event. Of all the CRA tunnels, only the area near the west portal of the San Jacinto tunnel would be subject to liquefaction, but this area would be easily accessible. The area above the west portal of the San Jacinto tunnel could also be subject to seismically induced landslides, but a project was completed in 1998 to mitigate the potential damage from a landslide at the portal. For the remainder of the tunnels, the potential to experience heavy damage from landslide or rockfalls is negligible. Despite traversing a highly seismic area, there are only three instances of the CRA tunnels crossing a known active fault: Whitewater Tunnel No. 2, Thousand Palms Tunnel No. 2, and Wide Canyon Tunnel No. 2. Of these three tunnels, Whitewater Tunnel No. 2 would likely experience the most significant displacement from a fault rupture.

For ground shaking, while a number of the tunnels could experience high levels of shaking based on estimated Peak Ground Acceleration (PGA), most of these tunnels are deep and constructed in hard rock, which is beneficial for their performance during an earthquake. However, approximately 4.2 miles of tunnel were identified as having a high potential of experiencing heavy damage from the Maximum Considered Earthquake (MCE). These are areas that have shallow cover (e.g. near portals) and experience high PGA values. It should be noted that the entire 4.2 miles would not be expected to be damaged from a single earthquake, but rather there would be isolated areas of damage with those identified tunnel sections. A CIP has been submitted to further investigate the vulnerability of these tunnel sections and to identify options to mitigate the risk.

The Whitewater Tunnel No. 2 was identified as having the greatest cumulative seismic risk. The tunnel is crossed by the Garnett Hills segment of the San Andreas Fault which, from the San Gorgonio Pass Seismic Event Vulnerability Study (Report No. 1484; 2014), could experience up to a 12 foot horizontal and 3 foot vertical offset from a rupture of the San Andreas Fault approximating the MCE. The tunnel could also experience very high levels of shaking from the MCE, and was constructed in compacted sands and gravels, which could negatively impact the performance against the shaking.

For the purpose of estimating repair times, a worst-case damage scenario was developed for the Whitewater Tunnel No. 2, and a tunnel repair workshop was conducted to get a realistic understanding of repair methods and repair times (reference Report No. 1485).

***Colorado River Aqueduct – San Gorgonio Pass Seismic Event Vulnerability Study (Report No. 1484),* July 2014, GeoPentech.** This study evaluated the potential for horizontal and vertical deformation following a large seismic event within the San Gorgonio Pass area. To assist in the study, a team of geoscientists experienced in assessing the potential for fault displacements along the southern San Andreas Fault System in the area of the San Gorgonio Pass was assembled under GeoPentech, Inc. The study incorporated the most recent information available regarding the seismicity of the area including: geology, geodesy, seismicity, paleoseismology, and tectonics.

The information gathered during the course of the study was used to develop a 3-dimensional deformation model of the San Gorgonio Pass area using Coulomb 3.3 (San Gorgonio Pass Model). The model was developed to estimate the surface fault displacement and deformation that would occur along and near the CRA within the San Gorgonio Pass as a result of future seismic events. The results of the San Gorgonio Pass Model were compared to current geologic and geomorphic data, which showed a reasonable reflection of the natural conditions of the area, validating the results of the model.

The MCE for the southern San Andreas Fault would be a rupture originating near the Salton Sea around Bombay Beach and extending through the San Gorgonio Pass up to between Wrightwood and Three

Points. Based on available geologic data, the most likely event on the San Andreas Fault to rupture in on the Garnett Hills Fault, which is a strand of the San Andreas Fault system located in the San Gorgonio Pass. Results from the San Gorgonio Pass Model indicate that an earthquake approximating the MCE for the Southern San Andreas Fault System could result in a horizontal offset of approximately 12 feet and a vertical deformation of approximately 3 feet at the Garnett Hills Fault crossing of the CRA. The vertical deformation would extend over the CRA for approximately 60 miles.

The seismic event would result in uplift along the longitudinal profile of the CRA with three separate peaks, with the last peak occurring at or near the Whitewater Tunnel No. 2 and resulting in a cumulative upward deformation of approximately 3 feet. This upward deformation of the CRA would reduce the flow carrying capacity of the aqueduct. An accompanying probabilistic rupture hazard analysis of the San Gorgonio Pass (Report No. 1470) showed that the above deformation occurring at the CRA crossing has a return period of approximately 750 years.

The Colorado River Aqueduct San Gorgonio Pass Seismic Event Vulnerability Study – Hydraulic Analysis, (Report No. 1558), **September 2014, Metropolitan Facility Planning and Hydraulics staff.** This study documents a detailed hydraulics analysis that evaluated the impact of a seismically induced vertical uplift of the CRA alignment over a length of approximately 60 miles, based on the uplift profile from the San Gorgonio Pass Seismic Event Vulnerability Study (Report No. 1484). The analysis showed that despite the uplift, Metropolitan would be able to continue flowing approximately 1300 cubic feet per second, approximately 80 percent of design flow, through the aqueduct after initial rapid repairs are completed. The analysis assumed free surface flow with a 3-foot minimum freeboard, the same as the current aqueduct design. Minor pressurization of the system could allow for some additional flow if required. The analysis also assumed that repairs to the CRA following the earthquake maintained the design cross sections and friction of the non-damaged CRA sections, and that no repairs were done to reestablish the grade.

Probabilistic Rupture Hazard Analysis of CRA at San Gorgonio Pass (Report No. 1470), **October 2014, Metropolitan staff.** This report is a supplemental report to Report No. 1484, "Colorado River Aqueduct – San Gorgonio Pass Seismic Event Vulnerability Study." The report documents the results of a probabilistic rupture hazard analysis of the CRA where it crosses the Garnett Hills segment of the Southern San Andreas Fault in the San Gorgonio Pass. The analysis showed that the projected 3-foot vertical and 12-foot horizontal surface deformation at the CRA crossing in the San Gorgonio Pass has a return period of approximately 750 years.

Colorado River Aqueduct Seismic Vulnerability Investigations – Summary Report (Report No. 1490)**, December 2014, Metropolitan Facility Planning staff.** This report briefly summarizes the results of the CRA seismic vulnerability studies (Reports 1478, 1484, 1485 and 1558).

Seismic Risk Assessment – Conveyance and Distribution System Tunnels (Report No. 1533), **March 2016, GeoPentech and Metropolitan Facility Planning staff.** This study evaluated the seismic risk of the 41 tunnels within Metropolitan's Conveyance and Distribution System to heavy damage during a future maximum considered earthquake (MCE) event that would adversely impact water deliveries to member agencies while the tunnel is out of service for repairs. The study was completed through a two part process. Part 1 screened each of the 41 tunnels and identified tunnels that were vulnerable to one or more seismic hazard, and could result in a loss of service to the member agencies (i.e., no backup capability) if flow through the tunnel is disrupted. Tunnels that met both criteria in Part 1 were deemed a potential seismic risk to Metropolitan's water delivery reliability and were pushed through to Part 2 of the process. Part 2 further evaluated each of the potential high-risk tunnels identified in Part 1 and numerically ranked each tunnels degree of seismic risk in order to identify which tunnel(s) may pose the greatest risk to Metropolitan's water delivery capability.

Appendix 8

Administrative Code Section 4503 "Suspension of Deliveries" and 9/21/06 IAS Clarification

This page intentionally blank.

§ 4503. Suspension of Deliveries.

(a) Whenever repairs or maintenance of the District's system, in the opinion of the Chief Executive Officer of the District, shall require suspension of delivery of water at any point or points, such delivery may be suspended without liability on the part of the District; provided, that except in cases of emergency, as determined by the Chief Executive Officer, notice of such suspension of service shall be given to the affected member public agency in advance of such suspension. Metropolitan will make a concerted effort to notify and work with member public agencies regarding all scheduled interruptions. The District will schedule non-emergency interruptions for the low demand months of the year, typically October through April, in coordination with the member public agencies.

(b) Each member agency shall have sufficient resources such as local reservoir storage, groundwater production capacity, system interconnections or alternate supply source to sustain a seven-day interruption in Metropolitan deliveries based on annual average demands. If a member public agency has been provided with a sixty (60) day notice of when an interruption in service is to occur, the member public agency shall be responsible for and reimburse direct costs, excluding labor costs, incurred by Metropolitan in the event that a scheduled non-emergency interruption of up to seven days is postponed or cancelled at the request of the member public agency as a result of insufficient local resources, and the District agrees to such cancellation or postponement. Direct costs shall be determined by Metropolitan's Chief Executive Officer, in consultation with the affected member agency. These direct costs shall be applied to the member public agency's water invoice following cancellation or postponement of the shutdown.

(c) Except in cases of emergency, the District, working with the member agencies, will produce a shutdown schedule each September for the annual shutdown season from October through April. The District will also develop a three-year shutdown schedule, which will give notice of the proposed shutdowns greater than seven days at least one-year in advance.

(d) Replenishment Service certifications will be adjusted for the reduction of credits that are accrued due to shutdowns that are greater than seven days. No adjustments will be made for shutdowns seven days or less unless the member agency provides a service to the District by serving another member agency in-lieu of District deliveries during a shutdown even if the shutdown is seven days or less.

Section 322.4 based on Res. 7260 – May 12, 1970, amending Res. 3896 – August 18, 1950; amended by M.I. 33642 – March 10, 1981. Section 322.4 repealed and Section 4503 adopted by M.I. 36464 – January 13, 1987, effective April 1, 1987; amended by M.I. 42278 - February 11, 1997; paragraph amended by M. I. 44812 - March 12, 2002; paragraph amended by M. I. 45943 – October 12, 2004; paragraphs assigned (a), (b), (c), & (d) designations and amended by M. I. 45988 – November 9, 2004.

2007 Integrated Area Study (IAS) Clarification

1. Original intent
    a. Communicated that MWD's system is interruptible
    b. Protected MWD from liability claims for required shutdowns
    c. Illustrated commitment to minimizing impacts
        i. Advanced notice & coordination
        ii. Non-emergency outages only during low flow months
    d. Required member agencies to make provisions for outages
        i. 7-day supply of average annual demands
        ii. No enforcement – no penalty

2. Updated text & interpretation
    a. Recognized changing conditions
        i. Increased member agency dependence upon MWD
        ii. Many agencies in non-compliance
        iii. Increased difficulty in storing treated water
    b. Revised requirement for member agency outage provisions
        i. Capability to sustain 7-day interruption (not limited to supply)
        ii. Penalty added for cancellation or postponement of outage

3. IAS clarification
    a. MWD planned outages are required to maintain long-term reliability
    b. Unplanned MWD outages may also occur
    c. Intent of 4503 was to encourage agency provisions for planned and unplanned outages
    d. Compliance not enforced (beyond interference with planned outages)
    e. Member agencies responsible for decisions regarding provisions for unplanned outages
    f. Regional flexibility improvements achieved through demand-driven LRP & IAS projects

EXECUTIVE SUMMARY

In February 2018, the Metropolitan Water District of Southern California (Metropolitan) published *Report No. 1551, Seismic Resilience First Biennial Report*, which defined Metropolitan's Seismic Resilience Strategy and identified a number of near-term goals to improve Metropolitan's seismic resilience. The *2020 Seismic Resilience Report Update* is a supplement to the *Seismic Resilience First Biennial Report* (2018 Report). The purpose of the update is to document revisions to Metropolitan's Seismic Resilience Strategy, document seismic-resilience-related studies completed since publication of the 2018 Report, list the achievements related to the seismic performance objectives and near-term goals identified in the 2018 Report, and communicate new performance objectives and goals that will further increase the seismic resilience of Metropolitan's system.

Since the publication of the 2018 Report, Metropolitan has initiated multiple studies that will improve planning for earthquake response. Completed studies include an evaluation of Metropolitan's emergency storage requirements and an evaluation of the susceptibility of the conveyance and distribution pipelines to liquefaction. Staff is also nearing completion of an assessment of the potential damage to the conveyance and distribution pipelines from different earthquake events.

In the last two years, Metropolitan has also completed construction for seismic upgrades to 17 structures. Additionally, Metropolitan substantially completed the initial round of seismic evaluations for above-ground structures constructed pre-1990, which in general pose an elevated seismic risk. Evaluation of above-ground structures built post-1990 has been initiated as well as evaluation of hydraulic structures (e.g., reservoir outlet towers) to assess their seismic risk when compared to current design practices.

Finally, Metropolitan conducted over 100 emergency response exercises, workshops, and seminars since February 2018, including two large functional exercises. These exercises help to ensure that Metropolitan staff is prepared for when an eventual earthquake occurs. Metropolitan also started a new five-year exercise plan in 2019 that will allow all of its member agencies to participate in at least one of Metropolitan's annual emergency exercises during the next five years.

Overall, Metropolitan has achieved many of the near-term goals that were proposed in the 2018 Report and is continuing the efforts to complete the few items that are still outstanding. The strategy outlined in the 2018 Report to develop the seismic resilience of the system is an ongoing process that will continue to evolve and adapt as new information becomes available.

Staff recommends changing the frequency of written update reports from its current two-year cycle to a frequency of a written report every five years, with the next written report to the Board in 2025. Staff will continue to provide annual oral updates on Metropolitan's Seismic Resiliency Strategy to the Board.

This Page Intentionally Left Blank

SECTION 1 PURPOSE

The Metropolitan Water District of Southern California (Metropolitan) owns and operates a complex conveyance, storage, treatment, and distribution system that serves a 5,200-square-mile service area within an active seismic region. Over its approximate 90-year history, Metropolitan has been proactive in mitigating seismic risk posed to the system, as well as improving its ability to maintain or quickly restore water deliveries following a major earthquake.

In February 2018, Metropolitan published *Report No. 1551, Seismic Resilience First Biennial Report* (2018 Report), which summarized Metropolitan's historical approach to mitigating seismic risk and defined the organization's current Seismic Resilience Strategy and the core components of that strategy. The report also identified performance objectives and near-term goals of the Seismic Resiliency Strategy. The 2018 Report is available on Metropolitan's website using the link below:

http://mwdh2o.com/PDF_About_Your_Water/SRS%20Report%201551_Final_030518A_Submit_Reduced.pdf

The *2020 Seismic Resilience Report Update* is a supplement to the 2018 *Seismic Resilience First Biennial Report*. The purpose of the update is to document recent revisions to Metropolitan's Seismic Resilience Strategy regarding emergency storage requirements, document seismic-resilience-related studies completed since publication of the 2018 Report, and list the achievements related to Metropolitan's Seismic Resilience of Structures Program, emergency response planning, and the seismic performance objectives and near-term goals identified in the 2018 Report. The report also identifies new performance objectives and goals that will further increase the seismic resilience of Metropolitan's system.

This Page Intentionally Left Blank

SECTION 2 BACKGROUND

Seismic Risk

Southern California is crossed by numerous faults of varying levels of activity that are capable of generating large earthquakes and causing widespread damage. The 2018 Report listed six earthquakes that occurred within or near Metropolitan's service area in southern California since 1900 - four strong earthquake events (M6.0 – 6.9) and two major earthquake events (M7.0 to M7.9).

In 2019, two significant earthquakes events occurred in the region. On July 4, 2019, a M6.4 earthquake occurred near Ridgecrest, approximately 122 miles north/northeast of Los Angeles. Then on July 5th, a M7.1 earthquake occurred in the same vicinity. While the earthquakes caused major damage to Ridgecrest and the surrounding communities, the earthquakes only caused mild shaking in the Los Angeles region due to the distance from the epicenter. However, these earthquakes are a reminder that earthquake risk is always present and that the region must take steps to prepare and respond.

A map showing significant (M6.3 and greater) earthquakes that have occurred in the southern California region since 1900 is provided in Appendix A.

Seismic Resilience Strategy

Metropolitan's Seismic Resilience Strategy is comprised of four components that encompass the various functions that promote the organization's seismic resilience objectives.

> **Planning** – Developing and maintaining a diversified water portfolio, system flexibility, and emergency storage supplies
>
> **Engineering** – Evaluation and mitigation of seismic risks of infrastructure and the water system as a whole
>
> **Operations** – Maintain effective emergency planning and response capabilities
>
> **Reporting** – Increase accountability and transparency of seismic resilience programs

Metropolitan's Seismic Resilience Strategy was described in detail in the 2018 Report, and the overall structure of the strategy is unchanged. A detailed breakdown of Metropolitan's Seismic Resilience Strategy is provided in Figure 2-1. The figure provides an overview of the comprehensive actions taken to mitigate impacts from large earthquakes, to quickly respond following an earthquake event, and to provide transparency regarding seismic risk and preparedness.

As shown in Figure 2-1, in addition to the activities conducted under the Planning, Engineering, Operations, and Reporting components of the Seismic Resilience Strategy, Metropolitan has continued its involvement with the Seismic Resilient Water Supply Task Force. The Seismic Resilient Water Supply Task Force is a collaboration between Metropolitan, the Department of Water Resources (DWR), and the Los Angeles Department of Water and Power (LADWP) to improve the seismic resilience of the imported water supply aqueducts.

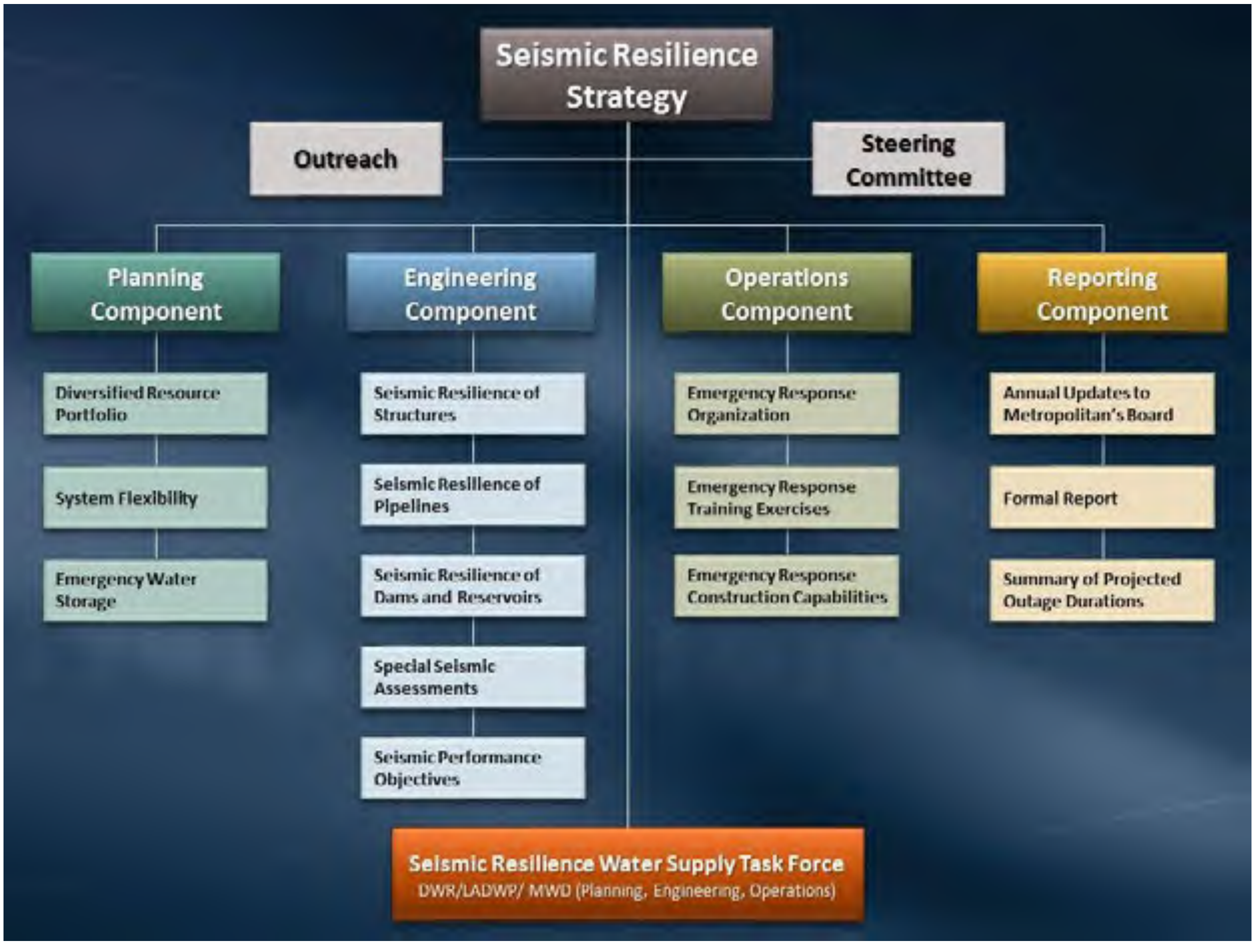

Figure 2-1: Detailed Breakdown of Metropolitan's Seismic Resilience Strategy

SECTION 3 SEISMIC RESILIENCE STRATEGY UPDATES/REVISIONS

Planning Component

Emergency Storage

Beginning in February 2018, Metropolitan and its member agencies convened a workgroup to evaluate regional storage, including the size and management of Metropolitan's emergency storage program. The goal of the emergency storage program evaluation was to update the emergency criteria and develop a revised methodology to determine emergency storage needs. The methodology and recommendation of the workgroup were described in a draft white paper, "2018 Evaluation of Regional Storage Portfolio: Draft Evaluation of Metropolitan's Emergency Storage Objective," and presented to Metropolitan's Board in May 2019[1].

The update of the emergency criteria was based on 1) newly revised potential outage durations for the region's imported water supplies – the Colorado River Aqueduct (CRA), the Los Angeles Aqueduct, and the State Water Project east and west branches – following a seismic event, and 2) a revisit of retail water demand and locally available supplies within the service area. The revised outages were developed as part of the Seismic Resilience Water Supply Task Force. The workgroup took into account the capabilities of member agencies when identifying reduction of retail water demand and local production during an emergency outage of imported supplies. This is a critical change in that the previous storage calculation assumed 100 percent local production during the outage period.

Diamond Valley Lake

The new emergency storage criteria considered various combinations of local demand reduction and supply production to develop an envelope of scenarios designed to prevent a shortage during an outage. Based on the range of potential scenarios, the workgroup recommended 750,000 acre-feet for the emergency storage program target, an increase from the previous planning target of 630,000 acre-feet.

The emergency storage is assumed to be distributed among the available capacities of existing Department of Water Resources and Metropolitan surface reservoirs located on the coastal side of the San Andreas Fault. Since member agency demands for supplemental water will be met through deliveries of supplies from storage, evaluation of spatial distribution of storage and most effective operation of the

[1] The Metropolitan Water District of Southern California, Water Planning and Stewardship Committee, Board Item 9-3, "Update of Metropolitan's Emergency Storage Objective," May 2019. http://www.mwdh2o.com/WhoWeAre/Board/Board-Meeting/Board%20Archives/2019/05-May/Letters/064883968.pdf

distribution system will be accomplished as part of Metropolitan's continued efforts and coordination within Metropolitan's storage portfolio evaluation or other regional planning processes.

System Flexibility

In July 2019, Metropolitan's Board of Directors authorized an amendment to the Administrative Code to enable delivery of member agency water supplies in Metropolitan's system in an emergency subject to the General Manager's approval[2]. The amendment is an effort to enhance water delivery reliability after a serious emergency in which 1) Metropolitan is unable to make deliveries to a member agency due to physical damage to Metropolitan's system resulting from a natural disaster or other emergency and 2) there are no alternate means for Metropolitan or the member agency to provide service to an area without the use of a portion of Metropolitan's system. The Administrative Code change clarifies the conditions of these emergency deliveries in a proactive way, instead of a reactive way in response to damaged infrastructure following a natural disaster or serious emergency.

Engineering Component

Seismic Resilience of Structures

Metropolitan has developed an ongoing program for evaluating and upgrading its above-ground facilities with the goal of protecting life safety and critical infrastructure to minimize water delivery interruptions following a seismic event. The initial round of evaluations focused on structures that were deemed likely to be more susceptible to damage from earthquakes – buildings constructed prior to 1990. Structures built after 1990 were constructed in accordance with the 1988 or later versions of the Uniform Building Code, which provides reasonable assurance of withstanding a design-level earthquake without catastrophic failure. The program procedure for the seismic resilience of Metropolitan's above-ground structures was described in the *Seismic Resilience First Biennial Report* and the program status as of January 2018 was provided. Since publication of that report, an additional 17 seismic upgrades have been completed. Figure 3-1 provides the overall status for the pre-1990 structures as of November 2019. Of the 311 pre-1990 structures identified, 63 percent were found to be acceptable and 37 percent (116 structures) potentially deficient following the rapid evaluation process. Of the 116 structures, 85 have either been seismically upgraded or are in design or construction. The remaining are largely structures that are not related to water delivery.

The program for seismically upgrading the above-ground structures is meant to be a continuous program, with the intent of reevaluating structures periodically. Structures found to be acceptable during the initial evaluation round may undergo a reevaluation, if warranted by new information such as a significant increase in seismic design force or displacement due to code revisions or newly discovered ground conditions, damage of structural components, severe material deterioration, and/or changes of occupancy.

[2] The Metropolitan Water District of Southern California, Engineering and Operations Committee, Board Item 8-4 "Authorize Amendments to the Administrative Code Regarding Deliveries of Member Agency Supplies in Metropolitan's System in an Emergency; the General Manager has determined that the Proposed Action is Exempt or Otherwise Not Subject to CEQA", July 2019. http://www.mwdh2o.com/WhoWeAre/Board/Board-Meeting/Board%20Archives/2019/07-July/Letters/07092019%20BOD%208-4%20B-L.pdf

As shown in Figure 3-1, evaluation of the pre-1990 structures related to water delivery has been substantially complete and the deficient structures are being addressed. Following the 1994 Northridge earthquake, and subsequent earthquakes in Taiwan, Japan, and New Zealand, substantial research in seismic design and code revisions has taken place. Post-1990 structures may or may not meet the current seismic performance standards, which has prompted Metropolitan to expand the seismic evaluation to post-1990 structures, a process which was initiated in early 2019 to further improve its seismic resilience. Twenty-six structures have been identified as part of the post-1990 structure list. Rapid evaluations have been completed on six structures, and none have been identified as seismically deficient.

As Metropolitan begins its evaluation of the post-1990 above-grade structures, staff is also initiating a process to identify and systematically evaluate below-ground structures such as vaults and manholes. Similar to the evaluation of above-ground structures, the prioritization of these facilities will consider potential impacts to water delivery and potential for loss of life.

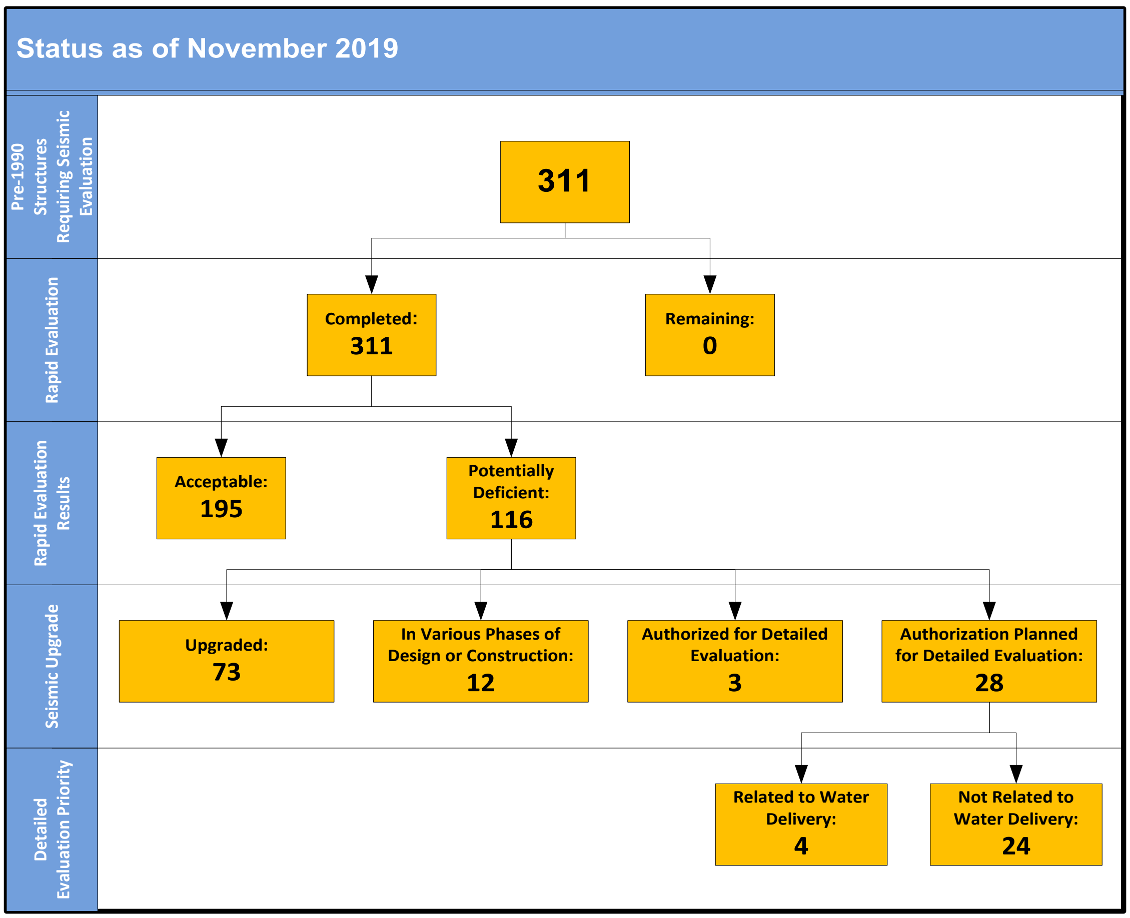

Figure 3-1: Status of Seismic Assessment and Upgrades of Pre-1990 Structures

Seismic Resilience of Pipelines

Metropolitan's pipelines have been constructed in conformance with standards of practice at the time of design. Historically, there have been very few prescriptive code requirements for seismic design of pipelines. Only recently have there been developments in mitigation options for large diameter pipelines, including improved techniques to analyze the response of structures and pipelines within the ground from shaking, increased post-earthquake data collection of ground motions and damage observations, and demonstrated performance of earthquake-resistant pipeline products.

In keeping with the goals of the Seismic Resilience Strategy, Metropolitan is developing seismic design criteria for new pipelines based on current state of practice, geotechnical and seismicity criteria, operating conditions, and asset management strategies. The planned design approach for new pipelines will be to establish performance criteria, identify seismicity and ground conditions along the alignment, and design the pipeline to resist damage from ground shaking and deformation. Specialized pipe joints and sections can be designed to accommodate ground deformation from fault displacement or liquefaction. For existing pipelines, seismic resilience will be incorporated as a component of pipeline rehabilitation projects. Metropolitan will evaluate each upgrade individually to balance risk, performance, and cost. See the Seismic Performance Objectives in this section for more information on the pipeline seismic design.

Metropolitan is in the early years of a 20-year program to rehabilitate its prestressed concrete cylinder pipelines (PCCP), which, at 163 miles, makes up approximately 20 percent of Metropolitan's conveyance and distribution system. The initial phase of the program will focus on the Second Lower Feeder, which will be upgraded with an interior steel liner. The new steel lining and the welded joints are designed to improve the seismic performance of the pipeline. For Reach 9 of the Second Lower Feeder, Metropolitan is investigating alternatives for realigning the portion of the pipeline that crosses the Newport-Inglewood Fault. One alternative being evaluated is to use specialized large-diameter earthquake-resistant steel pipe to accommodate fault displacement while maintaining structural integrity of the pipe for water conveyance.

Following this strategy, Metropolitan is completing the final design for rehabilitation of the Casa Loma Siphon Barrel No. 1 on the CRA in 2020. The Casa Loma Siphon Barrel No. 1 crosses the San Jacinto Fault Zone and is subject to long-term subsidence-induced deformation from groundwater pumping. The project will replace 800 feet of the existing 148-inch diameter concrete pipeline with two parallel barrels of 104-inch diameter earthquake resistant ductile iron pipe (ERDIP). The ERDIP joints are designed to accommodate ground displacements without failure, which will allow for uninterrupted service following a major earthquake.

Earthquake-Resistant Pipe

Seismic Resilience of Dams and Reservoirs

Metropolitan's ongoing strategy for managing the safety of its 24 dams includes five major components: (1) Detailed Inspections; (2) Monitoring & Reporting; (3) Facility Assessments; (4) Emergency Action Plans, including Inundation Maps; and (5) Capital Projects for dam improvements and upgrades.

Consistent with the goals of the Seismic Resilience Strategy, Metropolitan performs cyclical assessments of its facilities that include: 1) developing dam seismic performance criteria based on current state of practice, geotechnical and seismicity criteria, and operating conditions, 2) selecting design or safety evaluation earthquakes, 3) characterizing ground motions, 4) analyzing seismic performance of the dams and foundations, and 5) evaluating structural adequacy of dam appurtenant structures for earthquake loading.

Finally, Metropolitan has an ongoing Dam Safety Initiatives Program that has initiated several plans to improve Metropolitan's dam seismic safety and earthquake readiness. These initiatives are being coordinated with the California Division of Safety of Dams (DSOD) and Office of Emergency Services and include the following:

- Ongoing preparation of Emergency Action Plans, including inundation maps
- Performing training exercises at the dam site to test processes during a seismic event
- Providing training and guidance on overall dam safety
- Reviewing operation and maintenance methods for reservoir drawdown and operations after a seismic event
- Updating guidelines and procedures on protection against seismic risk
- Establishing a strong communications system on seismic information
- Performing structural strengthening of dams, including rehabilitation and improvement of spillways and inlet/outlet towers such as Lake Skinner Outlet Tower
- Improving dam safety instrumentation, monitoring, and reporting capabilities

Special Seismic Assessments

Metropolitan conducts studies to further the organization’s understanding of the vulnerability of the system to seismic hazards. The studies support emergency response training and planning for future earthquake events by estimating the magnitude of damage that may occur from various seismic events. Recently completed and ongoing studies are described below.

Completed Study:

> ***Report 1625 - Liquefaction Susceptibility Mapping for the Metropolitan Water District of Southern California’s Feeder System*** **(Carollo Engineers, Inc., 2019)**. The liquefaction susceptibility mapping study provides a relative scale of liquefaction susceptibility of deposits along Metropolitan’s conveyance and distribution system, given sufficient earthquake ground motions. Existing liquefaction maps available from the California Geological Survey provide a conservative overview of potentially liquefiable areas without any delineation for relative susceptibility. Areas are marked as either liquefiable or not liquefiable. The study utilized available geologic mapping data as well as publicly available groundwater data to map the relative liquefaction susceptibility of Metropolitan’s conveyance and distribution pipelines for historical high and modern (1999 to 2019) groundwater depths providing five levels of relative scaling of susceptibility from very high to very low. The results of the study will be used to identify specific locations that may be targeted for future site-specific detailed liquefaction analyses, help prioritize pipeline replacement projects, and assess alternative pipeline alignments.

Studies currently underway:

> ***Earthquake Damage Assessment of Metropolitan Water District Conveyance and Distribution Feeder System* (ABS Consulting, Inc.).** The study utilizes proprietary modeling software to estimate the potential number of pipeline breaks that may occur from various extreme earthquakes such as a Magnitude 7.8 earthquake on the South San Andreas Fault. The damage assessment model takes into account pipeline material and joint type, distance from earthquake source, and regional geologic conditions when developing the damage estimate. The results of the study will provide input into Metropolitan's earthquake emergency response planning and training activities, and help prioritize future pipeline seismic resilience enhancements. Anticipated completion is March 2020.

Seminars and Workshops

Metropolitan has recognized the importance of providing awareness of the seismic hazards and risks to Metropolitan, its member agencies, and sub-agencies and encouraging a transfer of knowledge of assessment and mitigation strategies to reduce seismic risk. Metropolitan ensures that risk awareness and knowledge transfer are promoted through active participation at various workshops.

In October 2019, Metropolitan co-hosted with LADWP the 11th Water System Seismic Conference. The conference is a bi-annual event that brings together utility, consulting, and academic professionals from the United States, Japan, and Taiwan to share knowledge in research, design practices, and construction technologies to prepare for and respond to seismic events. Conference topics included emerging design techniques, innovative construction practices, seismic damage assessments, seismic mitigation measures, and emergency response and recovery. In addition to co-hosting the conference, Metropolitan staff delivered four presentations on the organization's seismic resilience efforts. The papers and authors are listed in Appendix B.

Metropolitan Chief Engineer Providing Opening Remarks at 11th Water System Seismic Conference

In December 2019, Metropolitan co-sponsored the Earthquake Resilience Workshop for Water and Wastewater Utilities in Southern California. The workshop was a partnership with the United States Environmental Protection Agency and local utility and emergency management organizations to provide guidance and information to drinking water and waste water utilities to enhance their ability to enhance their resilience approach.

Staff also presented Metropolitan's seismic strategy and goals at the Member Agency Managers Meeting in August 2019. Staff described the various activities that Metropolitan conducts to understand the seismic risk and improve the overall resilience of the system. They also used the opportunity to promote the defense-in-depth approach to seismic resilience for the member agencies. This approach is a layered strategy of system hardening, emergency water supply diversification, and increased system flexibility, including potential interties between member agencies.

Seismic Performance Objectives

Structures

Metropolitan's facilities are categorized as either an essential facility or regular facility, depending on performance requirements of the structure in accordance with code requirements. The structures are then designed or rehabilitated to meet the design criteria specified in the applicable seismic codes.

Essential facilities are those that are required for Metropolitan's core business-water delivery. All structures that are directly or indirectly related to water conveyance, storage, treatment and distribution are considered essential. Additionally, structures that contribute to Metropolitan's business continuity are also considered essential. The performance objective for an essential facility is to allow for continuous operation of the structure with limited damage after a maximum considered seismic event. These essential facilities are designed or improved to allow for immediate occupancy or continuous operation after a major seismic event. As an owner/operator of essential lifeline facilities, Metropolitan's water-related facilities will remain functional for disaster relief and fire suppression following a seismic event.

For regular facilities, the objective is to allow safe evacuation of occupants with possible structural and non-structural damage. The performance objective is to ensure life safety and prevent collapse of the structure. A facility designed as a regular facility may require significant repair following a major seismic event.

Pipelines

Metropolitan's conveyance and distribution pipelines are considered essential pipelines that are required for post-earthquake response and recovery. The pipelines are intended to remain functional and operational during and following a maximum considered earthquake. No uncontrolled release of a substantial amount of water is permitted under this design scenario.

Metropolitan continuously improves its techniques to analyze the response of pipelines to a seismic event to improve its assessment and prediction of earthquake damage to these facilities. Post-earthquake data of ground motion and damage information are used to improve earthquake resilience design methodologies. The data collected is used in advanced seismic pipeline analysis that relies on finite element techniques for soil-structure 3d modeling. Innovation in the development of earthquake-resistant pipeline products contributes to better seismic performance.

For new pipeline seismic design, the performance objective is to ensure the pipeline, pipe joints, and pipe-to-structure connections are capable of resisting the seismic shaking resulting from earthquake wave propagation without permanent damage. As the pipeline crosses known earthquake faults, the system will be designed to accommodate the maximum anticipated ground movement from fault displacement using specialized joints or pipe sections. Automatic shutoff valves may be added on either side of the fault to increase system flexibility.

For existing pipeline seismic design, a comprehensive risk assessment of the system using the latest seismicity and pipeline fragility data will be performed. The vulnerabilities of each pipeline segment will be used to determine the priority and schedule of seismic rehabilitation. Seismic resilient design to resist shaking and accommodate fault displacement will be incorporated as components of the rehabilitation program. Each upgrade will be evaluated individually to balance risk, consequence, performance, and cost to define an economical long-term approach.

Operations Component

Emergency Response Training Exercises

In addition to training emergency response staff on National Incident Management System procedures, Metropolitan regularly conducts emergency response training exercises which have often been based upon a postulated seismic event.

Recent examples include:

- “ShakeOut“ Full-Scale Emergency Operations Center (EOC)/Incident Command Post (ICP) Exercise, October 17, 2019
- “Joint Infrastructure Security Exercise”- Tabletop Exercise with various Federal, State, and Local emergency management partner agencies- April 10, 2019
- “Operation Nomad”- Functional EOC/ICP and member agencies, November 14, 2018

In 2019, Metropolitan started a new five-year emergency exercise plan that will allow all of its member agencies to participate in at least one of Metropolitan’s annual emergency exercises. The first of these exercises was a tabletop exercise for the Orange County member agencies on August 29, 2019, which focused on a hypothetical incident at the Diemer Water Treatment Plant.

Metropolitan has conducted over 100 exercises since February 2018. This included two large functional emergency exercises for the EOC and multiple tabletop exercises, workshops, and seminars for the 12 Incident Command Posts located at the water treatment plants, conveyance and distribution facilities, and other strategic locations in Metropolitan’s service area.

The Metropolitan EOC also conducts monthly communication tests, which include Metropolitan’s emergency two-way radio system, on-line WebEOC system, Met-Alert mass notification system, and satellite phones. These monthly tests reach out to the member agencies, Treatment Plant Control Centers, ICPs, Metropolitan management, and the Department of Water Resources. These regular exercises help prepare Metropolitan and its member agencies to respond to future emergencies.

Emergency Response Capability

Metropolitan continues to maintain the necessary staffing, materials, and equipment to respond to two simultaneous pipeline breaks. The Machine Shop and Coating Shop at La Verne are available to fabricate pipe sizes up to 12 feet in diameter, and Metropolitan’s construction forces have the necessary equipment and expertise to make the repairs in-house. In addition, Metropolitan has upgraded its satellite phones to ensure communication ability following a seismic event and is in the process of installing high frequency radios at all Incident Command Posts (formerly Incident Command Centers) and the Emergency Operations Center.

Reporting Component

Formal Report

The interval for development of a formal report will be changed to every five years from the original two-year interval. Increasing the time interval between report updates will allow for a full Capital Investment Plan cycle to complete and for projects to move through concept, design, and construction.

Seismic Resilience Water Supply Task Force

The Seismic Resilience Water Supply Task Force (Task Force) is a collaborative effort involving Metropolitan, DWR, and LADWP to improve the seismic resilience of the imported water supplies to southern California. Following a major earthquake that disrupts the imported water supplies, the agencies would coordinate resources to repair the imported water supply aqueducts to ensure that deliveries are restored as quickly and to as many people as possible.

In March 2018, Metropolitan, DWR, and LADWP convened an aqueduct workshop to discuss lessons learned from recent large earthquakes in New Zealand, Japan, and Mexico; share each agency's approach to conducting seismic assessments; and discuss potential interties that may assist with recovery of water supply to the region. The group also had initial discussions on development of an emergency response plan specific to the Task Force.

Seismic Resilience Water Supply Task Force Aqueduct Workshop – March 2018

The Task Force also conducted two tabletop emergency exercises in 2018 and 2019. These exercises were used to give substance to some of the ideas in the Joint Agency Emergency Response Plan (ERP).

Metropolitan, DWR, and LADWP are developing a Water Mutual Assistance Agreement (WMUA), which will formalize the Task Force and define the reporting and accounting requirements for mutual assistance following a major seismic event that impacts imported water supplies. A draft of the Joint Agency ERP has also been completed. The Joint Agency ERP will be finalized along with the WMUA. The plan defines the scenarios that would trigger the deployment of the Multi-Agency Coordination Group, which enhances the collaboration in operation, reporting, and plan maintenance.

This Page Intentionally Left Blank

SECTION 4 SEISMIC RESILIENCE NEAR-TERM GOALS

Status of 2018 Listed Goals

The 2018 Seismic Resilience First Biennial Report identified near-term goals to further Metropolitan's seismic resilience objectives. The near-term goals are listed below along with an update of the work done to date.

System Level Goals

Goal	Conduct Rialto Pipeline Alternative Supply Needs Study
Status: Metropolitan completed an initial study to identify the near-term and long-term emergency supply needs for member agency demand from the Rialto Pipeline. The Rialto Pipeline is exclusively supplied from the California Aqueduct East Branch and is susceptible to extended disruption from an earthquake on the San Andreas Fault. The study also identified options to meet emergency supply needs. Metropolitan is currently working with member agencies to expand on the emergency supply options.	

Goal	Complete a Re-evaluation of Metropolitan's Emergency Storage Needs
Status: Metropolitan, in coordination with member agencies, completed a re-evaluation of Metropolitan's emergency storage needs and presented the recommendations to increase storage from 630,000 acre-feet to 750,000 acre-feet to Metropolitan's Board in May 2019. A description of the emergency storage re-evaluation is provided in Section 3.	

Goal	Complete a Comprehensive Evaluation of Metropolitan's Storage Programs
Status: Metropolitan, in coordination with member agencies, will complete the 2020 Integrated Water Resources Plan (IRP). Metropolitan will use newly developed demand and supply forecasts to analyze its entire supply portfolio, including all storage programs, in assessing regional reliability.	

Facility Level Goals

Goal	Complete Construction of Approved Seismic Upgrade Projects
Status: Construction has been completed for the listed projects. • Carbon Creek Pressure Control Structure • Ten Control Structures along the Allen-McColloch Pipeline • Diemer Administration Building • CRA Pump Plants Switch Houses (Five Buildings) • Weymouth West Wash Water Tank	

Goal	Conduct Studies, and Complete Design of Approved Upgrade Projects

Status:

- Assessment of potential seismic-induced damage to Metropolitan's water conveyance and distribution pipelines

  Studies to estimate damage from shaking and at fault crossings from large earthquakes and liquefaction susceptibility of pipelines are in progress with an estimated completion date of March 2020. See Special Seismic Assessments under Section 3.

- Seismic upgrade for Diemer West Filter Building

  Completed design and construction of seismic upgrades is ongoing with an estimated completion date of December 2020.

- Complete evaluation of options, design, and construction contract to strengthen CRA Whitewater Tunnel No. 2

  Preliminary design is underway.

- Investigate options to improve emergency raw water bypass capabilities at treatment plants

  Study is ongoing.

- Vulnerability Study of CRA electric transmission and distribution systems

  Completed CRA Electric Transmission System Towers Reliability Study, which considered seismic vulnerability in addition to other hazards.

- Seismic Upgrade of Water Quality Lab in La Verne

  Project is currently in design.

- Seismic Upgrade of Weymouth Administration Building

  Project is currently in design.

- Seismic Study of Lake Skinner Outlet Tower

  Completed voluntary seismic assessment of the tower which considered current dam safety criteria

Emergency Response Goals

Goal 1:	**Prepare and Conduct Emergency Exercises**
Status: • Conduct a joint agency workshop to prepare a draft Joint Agency Response Plan • Conduct high-level training for DWR, LADWP, and Metropolitan staff on the Joint Agency Emergency Response Plan • Run a functional exercise on the Joint Agency Emergency Response Plan *Metropolitan conducted joint agency tabletop exercises to develop the Joint Agency Emergency Response Plan in 2018 and 2019. The functional exercise will be conducted following finalization of the Joint Agency Emergency Response Plan.*	
Goal 2:	**Execute MOU to Allow for Coordinated Emergency Response**
Status: • Prepare draft Memorandum of Understanding (MOU) and submit for review • Secure LADWP, Metropolitan, and DWR approval for the MOU *The Joint Agency Mutual Assistance Agreement is in the final stages of review and is expected to be signed off by all three parties in the near future.*	

Seismic Task Force Goals

2018 Goals:	Collaborative LADWP, Metropolitan, and DWR Goals

Status:

- Discuss the applicability of lessons learned from seismic events in Japan, Chile, New Zealand, and Mexico

  The organizations continue to incorporate lessons-learned from seismic events, including the July 4, 2019, M 6.4 and July 5, 2019, M 7.1 events in Ridgecrest, California

- Compare each agency's approach to conducting seismic assessments

  In development of the Joint Agency Emergency Response Plan, the organizations provided detailed presentations of their seismic assessments and the underlying assumptions to their anticipated damage and outage durations.

- Meet with Southern California Edison (SCE) and Southern California Gas Co. to discuss the potential vulnerabilities of aqueduct power systems

  Metropolitan held discussions with staff from SCE and shared information on the respective systems and seismic vulnerabilities.

- Conduct workshops to explore potential aqueduct interties

  DWR and LADWP continue to investigate the potential for constructing an intertie between the State Water Project East Branch and the Los Angeles Aqueduct.

2019 Goals:	Collaborative LADWP, Metropolitan, and DWR Goals

Status:

- Establish a leadership structure for a coordinated response to major events

  The leadership structure for a coordinated response is described in the Joint Agency Emergency Response Plan

- Finalize a three-agency database of available emergency response resources

  Updating list of emergency response resources for 2020

2019 Goals:	**Collaborative LADWP, Metropolitan, and DWR Goals (cont'd)**

Status:

- Conduct a three-agency tabletop exercise

  Metropolitan hosted a tabletop exercise in October 2019.

- Develop a ShakeOut Scenario Response and Restoration Plan

  The ShakeOut Scenario is identified as one of the triggers that would initiate the Joint Agency Emergency Response Plan.

- Conduct a second three-agency functional exercise that includes energy utilities

  Conducted a functional emergency exercise at the Robert B. Diemer Water Treatment Plant with local Sheriff and Fire Departments, SCE, City of Yorba Linda Emergency Services, Yorba Linda Water District, Orange County Emergency Management, and the Water Emergency Response of Orange County.

Other Near-Term Goals

1. Develop a Standard Approach for Evaluating Non-Structural Elements:

   Metropolitan is in the process of studying industry standards applicable to Metropolitan and collecting approaches taken by other agencies.

2. Establish Additional Performance Objectives for new pipelines, retrofit of pipelines, and new and existing tunnels:

   Metropolitan is now designing new pipelines and tunnels and retrofitting existing pipelines and tunnels in accordance with current standards and incorporating additional seismic mitigation measures wherever practicable.

3. Investigate the Potential for Developing a Model to Prioritize Pipeline Rehabilitation:

   This is being addressed through the Asset Management efforts, with input from recent seismic studies on risk from potential damage from shaking, fault rupture, and liquefaction.

4. Enhance Member Agency Planning Efforts Regarding New Facilities and Emergency Response Programs:

   The Member Agency Managers Workshop was used to present the Seismic Resilience Strategy and objectives and Seismic Task Force findings.

5. Seek Approval for Detailed Seismic Studies

   This is an ongoing effort. As Metropolitan completes the rapid evaluations of the Post-1990 structures, detailed studies will be recommended for those structures found to be potentially deficient.

6. Support the Delta Conveyance Project (part of the former proposed California WaterFix Project)

Metropolitan will continue to support the Delta Conveyance Project to increase the seismic resiliency of the Bay-Delta portion of the State Water Project.

2020 Update Near-Term Goals

The following section lists new near-term goals that will further Metropolitan's objective of seismic resilience. These goals are anticipated to be completed before the next update in 2025.

System Level Goals

Goal	Conduct Special Seismic Studies
• Update 2006 System Reliability Study, which analyzed the impacts of various single outage scenarios on Metropolitan's ability to meet member agency demand	

Goal	Conduct Planning Studies
• Complete the 2020 IRP and comprehensive distribution system study under collaborative regional process. Update the emergency storage objective based on new IRP goals and forecasts.	

Facility Level Goals

Goal	Complete Construction of Approved Projects
• Weymouth West Wash Water Tank Seismic Upgrade • Union Station Headquarters Building Seismic Upgrade • Diemer West Filter Seismic Upgrade • CRA Casa Loma Siphon Barrel No. 1 Replacement	

Goal	Complete Design of Approved Seismic Upgrade Projects
• Weymouth Administration Building Seismic Upgrade and Building Improvements • La Verne Water Quality Lab and Field Engineering Building Seismic Upgrades and Building Improvements • CRA Whitewater Tunnel No. 2 Seismic Upgrades • Lake Mathews Disaster Recovery Facility Seismic Upgrades • Upper Feeder San Gabriel Tower Seismic Upgrade • Weymouth Inlet Channel Structural Upgrades	

Goal	Seismic Upgrade of Below Ground Structures
• Initiate evaluation of below-ground structures. Identify and list all structures. Develop a prioritization system for evaluation.	

Task Force Goals

Goal	Emergency Response Plan and Exercises
• Conduct annual exercises to ensure familiarity with Joint Agency Emergency Response Plan • Semi-annual verification of emergency contact list for DWR, Metropolitan, and LADWP	

Other Near-Term Goals

- Promote to member agencies the Defense-in-Depth approach to seismic resilience as recommended in *Report 1335 – Potential Effects of Southern California Seismic Events on Metropolitan Deliveries* (January 2009).
- Continue to gain and share knowledge about seismic resilience through participation in workshops and conferences.
- Complete rapid evaluations for post-1990 above-grade structures.

Appendix 10

METROPOLITAN'S ENERGY INTENSITY INFORMATION, INCLUDING CONVEYANCE AND DISTRIBUTION GENERATION

Appendix 10
METROPOLITAN'S ENERGY INTENSITY INFORMATION

Introduction

The Metropolitan Water District of Southern California is a wholesale water agency that distributes water to its 26 member agencies. These agencies receive treated and untreated water through Metropolitan's 830 miles of interconnected pipelines. There are over 400 service connections to the 26 member agencies located throughout Metropolitan's 5,200 square mile service area.

Metropolitan has always recognized the relationship between water and energy. In addition to being one of the original contractors for power from Hoover Dam in 1937, Metropolitan also paid for half of the cost of the Parker Dam power plant. The energy Metropolitan receives from these facilities provides greenhouse gas (GHG)-free electricity for pumping along the Colorado River Aqueduct. Metropolitan's conveyance and distribution system is also designed to minimize pumping. Imported supplies flow by gravity through Metropolitan's treatment plants and distribution system to the member agencies.

Water-Related Energy Use in California

The Water-Energy Nexus (W-E Nexus) recognizes that water supplies and energy supplies are interrelated. Water supplies require energy for heating and cooling, but also for transporting, treating and disposing. Likewise, energy supplies require water for cooling, fuel extraction and processing and hydropower production.

State agencies, water districts, and other stakeholders began to study the important link between energy and water in the 2000s. Since then, it has been widely reported that California's "Water Sector" uses 19 percent of the state's electricity and 32 percent of the state's natural gas not used for power generation.

The original source for these facts is the California Energy Commission's 2005 "California's Water – Energy Relationship" report (CEC-700-2005-011-SF, Nov. 2005[1]). In the report, the CEC analyzed energy use data for 2001 and disaggregated the 19 percent into urban water supply, wastewater treatment, customer end uses, and agriculture. Based on the CEC's analysis, approximately 3 percent of California's electrical use in 2001 was associated with urban water agency conveyance, treatment, and distribution. Customer end-uses such as the heating and cooling of water represented 11.1 percent. Another 0.8 percent was attributed to wastewater treatment and 4.2 percent was associated with agricultural uses. Table A.10-1 presents the water related energy use in California adapted from the 2005 CEC report.

The 3.8 percent of electricity associated with urban water supply and wastewater treatment represent the "embedded energy" in water.

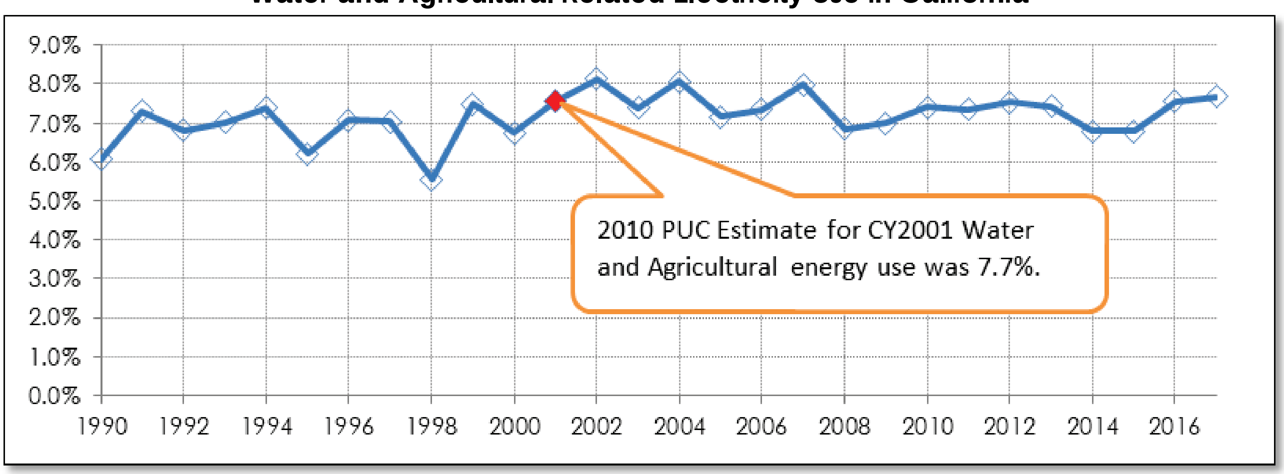
[1] https://www.energy.ca.gov/2005publications/CEC-700-2005-011/CEC-700-2005-011.PDF

Table A.10-1
Water Related Energy Use in California[2]

	Electricity (Gigawatt-hour)	Natural Gas (Million Therms)
Urban Water Supply	**7,554**	**19**
Wastewater Treatment	2,012	27
Urban End Users	27,887	4,220
Agricultural Total	10,560	18
Total Water Sector Use	**48,013**	**4,284**
Total California Use	**250,494**	**13,571**
Urban Water Supply	**3.0%**	**0.1%**
Wastewater Treatment	0.8%	0.2%
Urban End Users	11.1%	31.1%
Agricultural Total	4.2%	0.1%
Total Water Sector Use	**19.2%**	**31.6%**

In 2010, the California Public Utilities Commission (PUC) reevaluated water-related energy use and estimated that 7.7 percent of the State's electricity was used for urban water supply, wastewater treatment, and agricultural-related pumping and treatment.[3] This is close to the CEC report estimate for those three sectors. While water-related electricity use varies from year to year, it has fluctuated between 6 percent and 8 percent over the past 30 years, as shown in Figure A.10-1.

Figure A.10-1
Water and Agricultural Related Electricity Use in California[4]



[2] "California's Water – Energy Relationship" report (CEC-700-2005-011-SF, 2005)
[3] Embedded Energy in Water Studies Study 1: Statewide and Regional Water-Energy Relationship (Public Utilities Commission, 2010, page 58)
[4] CEC: California Energy Consumption Data Base: http://ecdms.energy.ca.gov/

In response to California's GHG emission goals, Metropolitan and many other water utilities are taking steps to reduce water-related energy use and emissions. This includes increasing energy recovery in conveyance and distribution systems, developing renewable energy projects, performing energy studies, auditing facility energy usage, and other related actions. Additionally, the conservation programs administered by Metropolitan and the member agencies save embedded energy along with the energy associated with customer end uses. Section 3.8 contains a description of Metropolitan's energy sustainability initiatives and proposed Climate Action Plan.

Metropolitan's Energy Intensity

Under CWC 10631.2(a), urban water management plans "Shall include any of the following information that the urban water supplier can readily obtain:"

1. An estimate of the amount of energy used to extract or divert water supplies.
2. An estimate of the amount of energy used to convey water supplies to the water treatment plants or distribution systems.
3. An estimate of the amount of energy used to treat water supplies.
4. An estimate of the amount of energy used to distribute water supplies through its distribution systems.
5. An estimate of the amount of energy used for treated water supplies in comparison to the amount used for nontreated water supplies.
6. An estimate of the amount of energy used to place water into or withdraw from storage.
7. Any other energy-related information the urban water supplier deems appropriate.

This section provides Metropolitan's energy intensity information according to these guidelines. Due to the mixing of water supplies before and after treatment, Metropolitan's complex distribution system, and the large number of service connections, Metropolitan provides system-wide energy intensity values. As operational conditions change from month to month and year to year, Metropolitan's energy use and energy intensity also vary.

Metropolitan's operational control includes the Colorado River Aqueduct (CRA) but does not include the State Water Project (SWP). However, excluding upstream embedded energy from the SWP would not represent an accurate estimate of the energy embedded in Metropolitan's water supplies. To avoid potential misinterpretation of the data provided, this Appendix reports Metropolitan's energy intensity information with upstream SWP embedded energy.

Metropolitan's energy intensity for the water it provides to its member agencies is broken down into the following functions and described below:

- Source
- Conveyance
- Treatment
- Distribution
- Storage

Source

The water Metropolitan receives comes from two sources: (1) the California Department of Water Resources' (DWR) State Water Project, and (2) the Colorado River. The energy required to extract or divert water from these sources is reported in conveyance.

Conveyance

The energy requirements from the two conveyance systems supplying Metropolitan's water have been combined, along with the volume of water delivered, into a single weighted energy intensity value. This method provides an energy intensity estimate which can then be used by other water agencies and stakeholders. As the blend of water from the SWP and the Colorado River changes each year, the total energy consumption for conveyance also varies.

Metropolitan's energy intensity for conveyance also accounts for consequential and non-consequential hydropower. Consequential hydropower is hydropower produced as the sole result of a water demand or use. Non-consequential hydropower is hydropower produced as the result of some combination of water demand deliveries and releases for other purposes such as flood control. The non-consequential hydropower from Hoover Dam and the SWP's Hyatt-Thermalito Complex are discussed in the following sections.

Colorado River

Metropolitan conveys water from the Colorado River through its Colorado River Aqueduct (CRA). The water is pumped through five pumping plants to reach Metropolitan's service area. The nominal energy intensity of water conveyed through the CRA is 2,000 kWh/AF.

There are no recovery generating plants along the CRA. However, the water that Metropolitan pumps from the Colorado River has been released from Lake Mead through the Hoover Dam generators. Metropolitan receives 27.1 percent of the energy produced at Hoover. This energy is used to power the CRA pumps. The production rate (kWh/AF) at Hoover depends on several factors, including the elevation of Lake Mead. The USBR updates this value monthly. Metropolitan incorporates its share of the energy produced at Hoover in the calculation of the CRA conveyance energy requirement.

State Water Project

Metropolitan is a contractor for water from DWR's SWP. The SWP uses a combination of natural and man-made systems to move water from Lake Oroville on the Feather River in northern California, through the Sacramento/San Joaquin River Delta (Delta), and into the California Aqueduct for delivery to Southern California and other regions. DWR conveys water through the California Aqueduct using a series of pumps and hydroelectric generators. Metropolitan receives water from DWR through the West Branch of the California Aqueduct at Castaic Lake and from the East Branch of the California Aqueduct at several locations in San Bernardino and Riverside Counties.

The California Aqueduct's net energy intensity for the water received from the West Branch is 2,580 kWh/AF and for the East Branch it is 3,236 kWh/AF. These values are the nominal pumping requirements of the SWP pumps (Banks, Dos Amigos, Buena Vista, Teerink, Chrisman, Edmonston, Oso, and Pearblossom) less the nominal generation values from the West and East Branch recovery generating plants (Warne, Castaic, Alamo, Mojave, and Devil Canyon). These values exclude pumping and generating at the San Luis Gianelli Plant.

The SWP also produces power at its Hyatt-Thermalito complex (HTC) near Lake Oroville and the Feather River in northern California. DWR releases water from Lake Oroville which flows through the HTC hydro generators and produces power for the SWP. State Water Project Contractors, including Metropolitan, pay for the HTC based on their share of the SWP's Variable Operation, Maintenance, Power and Replacement (OMP&R) Component of the Transportation Charge. To determine the benefit Metropolitan receives from the HTC generation in calculating the Energy Intensity of SWP conveyance, this same OMP&R share (percentage) is used with the total generation from the HTC. From 2004 through 2018, Metropolitan's share of the HTC costs has ranged from 60.2 percent to 74.3 percent. A multi-year average percentage has been used to reduce the year-to-year volatility of this factor and calculate the non-consequential energy included in Metropolitan's conveyance energy intensity. Table A.10-2 presents the 2018 conveyance energy intensity with upstream SWP embedded energy.

The SWP contract has specific provisions on how and when to account for various water deliveries and the associated costs. This will result in differences between the SWP billing values and the amount of water delivered to Metropolitan from the SWP.

Table A.10-2
2018 Conveyance Energy Intensity with Upstream SWP Embedded Energy

	With SWP Embedded Energy
Net Energy Use (kWh)*	3,050,621,000
Water Conveyed (AF)	1,588,958
Energy Intensity (kWh/AF)	1,919.9

* Accounts for non-consequential hydropower generation of 94,161,800 kWh from Hoover Dam on the Colorado River and 861,900,000 kWh from the Hyatt-Thermalito Complex on the State Water Project.

Treatment

Metropolitan operates five treatment plants to provide potable water to its Member Agencies. The estimated amount of energy used to treat water supplies has been calculated by dividing the annual amount of energy consumed at the plant sites by the amount of water treated. In order to meet water quality regulations, Metropolitan has retrofitted its treatment plants to use ozone, rather than chlorine, as the primary disinfectant during treatment (chlorine and ammonia are added after filtration for a disinfection residual in the distribution system). Metropolitan generates ozone on-site at each treatment plant. The ozone generation process has increased the energy required for treating Metropolitan's supplies. Table A.10-3 presents the treatment energy intensity for 2018.

Table A.10-3
2018 Treatment Energy Intensity

	2018
Energy Use (kWh)	53,608,000
Water Treated (AF)	769,398
Energy Intensity (kWh/AF)	69.7

Metropolitan has also installed solar energy at three of its treatment plants with a combined capacity of five megawatts. The electricity generated by these facilities meets between 15 percent and 20 percent of the energy demands of those plants. Solar energy is added to the grid power used at each plant to estimate a total energy intensity value. In 2018, Metropolitan generated 10,409,000 kWh of solar energy from these facilities, reducing the electricity purchased from the grid and its associated GHG emissions.

Distribution

Due to the high elevations at which Metropolitan receives water from the SWP and CRA conveyance facilities, minimal pumping (and electricity use) is needed to distribute treated and untreated water to its Member Agencies. Gravity, not electricity, drives water supply deliveries through most of Metropolitan's distribution system.

In addition, Metropolitan has 16 recovery hydroelectric generating plants located throughout its distribution system. The generators produce electricity from the water flowing through the pipelines. These plants generate more power than is consumed from distribution pumping. Without the hydroelectric generators, embedded energy in the water would be reduced at facilities called pressure control structures and the potential for energy production would be lost. The energy used in the pumping plants and produced by the generators has been netted, with the result divided by water deliveries to calculate the distribution energy intensity.

Weather variation has a significant impact on distribution system energy intensity. In dry years with low SWP deliveries, Metropolitan generates less distribution system hydropower and may need to increase pumping to deliver CRA supplies throughout the region. Table A.10-4 presents the distribution system net energy intensity for 2018.

Table A.10-4
2018 Distribution System Net Energy Intensity

	2018
Pumping (kWh)	4,753,000
Hydropower Generation (kWh)	-239,699,000
Net Distribution Energy Use (kWh)	-234,946,000
Water Delivered (AF)	1,540,022
Energy Intensity (kWh/AF)	-152.6

Storage

Metropolitan maintains significant storage facilities and programs both inside and outside its service area. However, Metropolitan does not use any energy for storage programs under its "span of control." Water is delivered by gravity flow. External water storage and recovery are managed by other parties and are often transacted through exchange arrangements. Water delivered to Metropolitan from these storage programs is accounted for in conveyance energy intensity.

Metropolitan's Annual Energy and Energy Intensity

Energy and energy intensity information is provided for each of the non-zero processes listed above: Conveyance; Treatment; and Distribution. As noted previously, these values vary from year to year due to operational changes and differences in water supply availability. An estimated overall energy intensity is provided for untreated and treated water deliveries for 2018 and for a six-year average in the tables below. Both estimates account for non-consequential hydropower. Table A.10-5 presents the treated and untreated water energy intensity for year 2018. Table A.10-6 presents the average treated and untreated water energy intensity for 2013 through 2018. Figure A.10-2 shows Metropolitan's energy use for 2013 through 2018 and highlights the impacts of hydrological conditions on Metropolitan's energy use.

Table A.10-5
2018 Treated and Untreated Water Energy Intensity

	With SWP (kWh/AF)
Conveyance*	1,919.9
Treatment	69.7
Distribution	-152.6
Total Treated	1,837.0
Total Untreated	1,767.3

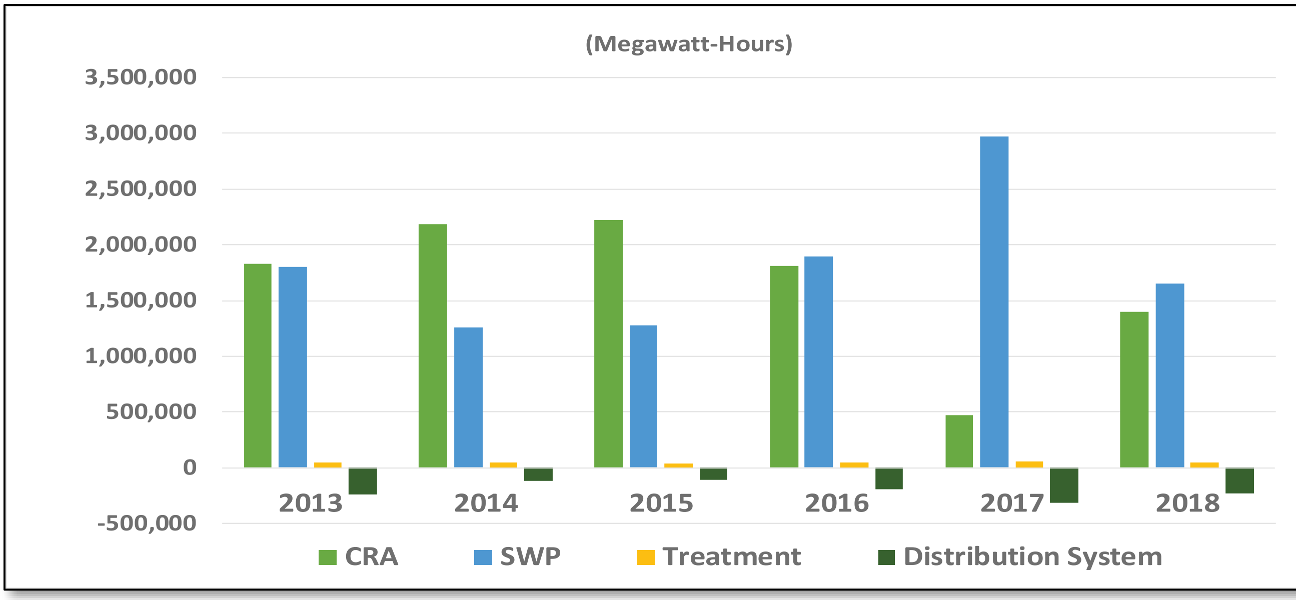
*Accounts for hydropower generation from Hoover and Hyatt/Thermalito

Table A.10-6
Average Treated and Untreated Water Energy Intensity (2013 – 2018)

	With SWP (kWh/AF)
Conveyance*	1,928.0
Treatment	57.0
Distribution	-121.9
Total Treated	1,863.0
Total Untreated	1,806.0

*Accounts for hydropower generation from Hoover and Hyatt/Thermalito

Figure A.10-2
Variations in Metropolitan Energy Use (2013-2018)



Greenhouse Gas Emissions

Metropolitan voluntarily reports its GHG emissions from all sources to The Climate Registry (TCR). TCR implements a GHG registry for California entities and develops protocols for GHG reporting. The data provided in TCR's registry is publicly accessible and transparent. Metropolitan's annual GHG data and those for many other water agencies are available through TCR's CRIS website[5]. To guarantee data quality, TCR requires published GHG information to be audited by a certified verification expert. Metropolitan has been auditing and reporting its annual GHG emissions to TCR since 2005.

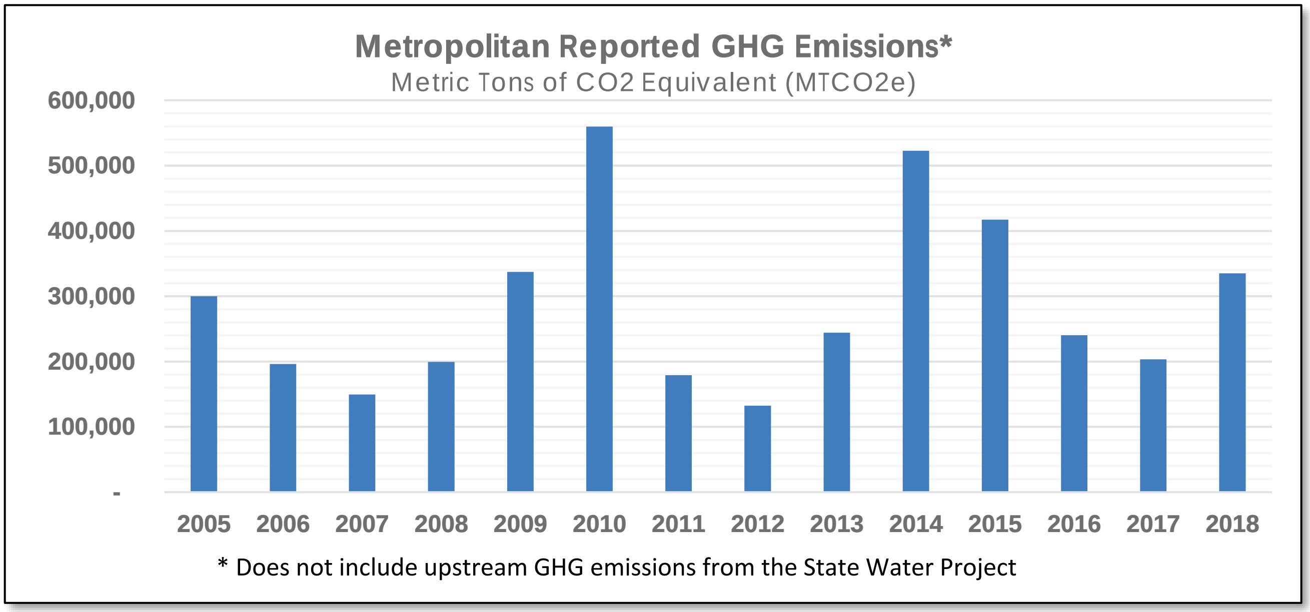
As with energy intensity, Metropolitan's GHG emissions vary due to hydrology. Over 95 percent of Metropolitan's GHG emissions are derived from electricity use, primarily from the CRA. In dry years, Metropolitan purchases additional grid electricity to accommodate higher CRA deliveries and uses more energy for distribution system pumping. The combination of higher electricity use coupled with higher GHG emission factors for purchased electricity cause Metropolitan's GHG emissions to spike in dry years. The opposite is true in wet years. Lower CRA deliveries are met with zero-carbon electricity from Hoover and Parker dams. In recent years, Metropolitan's GHG emissions have swung from 522,600 tons of CO2e emitted during the record low SWP allocation year in 2014 to 203,400 tons of CO2e emitted during the record wet year in 2017. Metropolitan's 10-year average of 317,100 tons of CO2e includes two dry-year/wet-year cycles.

[5] The Climate Registry CRIS GHG Database: https://www.theclimateregistry.org/tools-resources/reporting-toolkit/cris-resources/

Unlike Metropolitan's embedded energy described above, Metropolitan's reported GHG emissions do not include upstream SWP emissions. Metropolitan is participating in TCR's new Water-Energy Nexus GHG Registry and will be able to provide additional GHG metrics in the future.

The California Air Resources Board (CARB) tracks state-wide GHG emissions from all sources on an annual basis[6]. Compared to CARB's GHG inventory, Metropolitan's CO2e emissions represented 0.12 percent of the state's total emissions in 2014 and 0.05 percent in 2017. Additional information on Metropolitan's GHG emissions and Climate Action Plan are contained Section 3.8. Figure A.10-3 presents Metropolitan GHG emissions for 2005 through 2018.

Figure A.10-3
Metropolitan GHG emissions



DWR Required Water-Energy Nexus Table: Process Approach

Table A.10-7 contains Metropolitan's required Water-Energy Table for CY2018 using the Water Supply Process Approach in Table O-1A.

The table shows Metropolitan's energy intensity with upstream SWP embedded energy and non-consequential generation included.

Note that Metropolitan uses an alternative approach for calculating total or system-wide kWh/AF. Metropolitan's approach adds the energy intensity of the individual components to derive a system-wide total, where the required table divides the total net energy use by total deliveries. As a result, the system-wide kWh/AF total described in Table A.10-6 varies slightly from DWR's required Table A.10-7. Metropolitan also incorporates non-consequential hydropower production in its energy intensity calculations.

[6] https://ww2.arb.ca.gov/ghg-inventory-data; California's GHG emissions were 444.7 million tons of CO2e in 2014 and 424.1 million tons of CO2e in 2017, the latest year available.

Quantity of Self-Generated Renewable Energy

10,409,000 kWh

Data Quality (Estimate, Metered Data, Combination of Estimates and Metered Data)

Combination of Estimates and Metered Data

Data Quality Narrative:

Assumes Colorado river energy intensity at 2,000 kWh/AF; SWP East Branch at 3,236, and SWP West Branch at 2,580.
Energy use for the treatment and distribution processes are metered. Non-consequential hydropower is calculated from metered data.
Detailed descriptions of the methodology are contained in the appendix.

Narrative:

This table incorporates upstream State Water Project conveyance deliveries, energy use, consequential and non-consequential energy generation from Hoover Dam and the SWP Hyatt-Thermalito Complex.
Including upstream SWP imbedded energy represents the applicable energy intensity of Metropolitan's water supplies as delivered to its Member Agencies.

Metropolitan uses an alternative method for calculating overall energy intensity by adding the processes to derive a total utility value as described above.
Using Metropolitan's additive methodology, the total utility energy intensity for treated water would be 1,837 kWh/AF instead of 1,863 kWh/AF in the table above.

Total non-consequential hydropower included in 2018 conveyance: 956,021,000 kWh
- Hoover Dam non-consequential hydropower: 94,162,000 kWh
- Hyatt-Thermalito non-consequential hydropower: 861,859,000 kWh

Metropolitan delivers both treated and untreated water to its member agencies.

Glossary

Water-Energy Nexus: The recognition of the link between water supplies and energy supplies

Energy Intensity: A measure of the energy required to deliver, or process water expressed in kilowatt hours per acre-foot (kWh/AF)

Embedded Energy: The amount of energy required to deliver water supplies from a source to a delivery point. Also expressed in kilowatt hours per acre-foot (kWh/AF).

Greenhouse Gas Intensity: a measure of the overall greenhouse gasses required to deliver or process water, expressed in GHG/AF.

Hydropower: Renewable energy produced by water powering a turbine to produce electricity.

Water Sector: The water sector in the W-E Nexus is broadly defined to include customer end-uses of water such as heating or cooling; pumping and treating urban and agricultural water supplies; and wastewater disposal.

Consequential Hydropower: Hydropower produced as the sole result of a water demand or use. An example would be a hydropower recovery plant on an aqueduct that generates power as demands dictate flows in the aqueduct.

Non-consequential Hydropower: Hydropower produced as the result of some combination of water demand and other requirements such as flood releases or environmental flows.

The Climate Registry: A California non-profit organization tasked with managing a voluntary GHG registry for the State as well as implementing a voluntary GHG registry specifically for water-related GHG emissions.

Appendix 11

QUANTIFYING REGIONAL SELF-RELIANCE AND REDUCED RELIANCE ON WATER SUPPLIES FROM THE DELTA WATERSHED

Appendix 11
METROPOLITAN'S
REDUCED DELTA RELIANCE REPORTING

A.11.1 Background

Under the Sacramento-San Joaquin Delta Reform Act of 2009, state and local public agencies proposing a covered action in the Delta,[1] prior to initiating the implementation of that action, must prepare a written certification of consistency with detailed findings as to whether the covered action is consistent with applicable Delta Plan policies and submit that certification to the Delta Stewardship Council.[2] Anyone may appeal a certification of consistency, and if the Delta Stewardship Council grants the appeal, the covered action may not be implemented until the agency proposing the covered action submits a revised certification of consistency, and either no appeal is filed, or the Delta Stewardship Council denies the subsequent appeal.[3]

An urban water supplier that anticipates participating in or receiving water from a proposed covered action such as a multi-year water transfer, conveyance facility, or new diversion that involves transferring water through, exporting water from, or using water in the Delta should provide information in their 2015 and 2020 Urban Water Management Plans (UWMPs) that can then be used in the covered action process to demonstrate consistency with Delta Plan Policy WR P1, Reduce Reliance on the Delta Through Improved Regional Water Self-Reliance (WR P1).[4]

WR P1 details what is needed for a covered action to demonstrate consistency with reduced reliance on the Delta and improved regional self-reliance. WR P1 subsection (a) states that:

(a) Water shall not be exported from, transferred through, or used in the Delta if all of the following apply:

> *(1) One or more water suppliers that would receive water as a result of the export, transfer, or use have failed to adequately contribute to reduced reliance on the Delta and improved regional self-reliance consistent with all of the requirements listed in paragraph (1) of subsection (c);*
>
> *(2) That failure has significantly caused the need for the export, transfer, or use; and*
>
> *(3) The export, transfer, or use would have a significant adverse environmental impact in the Delta.*

WR P1 subsection (c)(1) further defines what adequately contributing to reduced reliance on the Delta means in terms of (a)(1) above.

(c)(1) Water suppliers that have done all the following are contributing to reduced reliance on the Delta and improved regional self-reliance and are therefore consistent with this policy:

> *(A) Completed a current Urban or Agricultural Water Management Plan (Plan) which has been reviewed by the California Department of Water Resources for compliance with the applicable requirements of Water Code Division 6, Parts 2.55, 2.6, and 2.8;*

---

[1] Water Code, § 85057.5; Cal. Code Regs. tit. 23, § 5001.
[2] Water Code, § 85225; Delta Plan, App. D.
[3] Water Code, §§ 85225.10-85225.25; Delta Plan, App. D.
[4] Cal. Code Regs., tit. 23, § 5003.

(B) Identified, evaluated, and commenced implementation, consistent with the implementation schedule set forth in the Plan, of all programs and projects included in the Plan that are locally cost effective and technically feasible which reduce reliance on the Delta; and

(C) Included in the Plan, commencing in 2015, the expected outcome for measurable reduction in Delta reliance and improvement in regional self-reliance. The expected outcome for measurable reduction in Delta reliance and improvement in regional self-reliance shall be reported in the Plan as the reduction in the amount of water used, or in the percentage of water used, from the Delta watershed. For the purposes of reporting, water efficiency is considered a new source of water supply, consistent with Water Code Section 1011(a).

The analysis and documentation provided below include all of the elements described in WR P1(c)(1) that need to be included in a water supplier's UWMP to support a certification of consistency for a future covered action.

A.11.2 Summary of Expected Outcomes for Reduced Reliance on the Delta

As stated in WR P1(c)(1)(C), the policy requires that, commencing in 2015, UWMPs include expected outcomes for measurable reduction in Delta reliance and improved regional self-reliance. WR P1 further states that those outcomes shall be reported in the UWMP as the reduction in the amount of water used, or in the percentage of water used, from the Delta.

The expected outcomes for Metropolitan's Delta reliance and regional self-reliance were developed using the approach and guidance described in Appendix C of DWR's Urban Water Management Plan Guidebook 2020 (Guidebook Appendix C) issued in March 2021.

The data used in this analysis represent the total regional efforts of Metropolitan and its member agencies and their customers (many of them, retail agencies) and were developed in conjunction with Metropolitan's member agencies as part of the UWMP coordination process as described in Section 5 of Metropolitan's UWMP. In accordance with UMWP requirements, Metropolitan's member agencies and their customers (many of them, retail agencies) also report demands and supplies for their service areas in their respective UWMPs. The data reported by those agencies are not additive to the regional totals shown in Metropolitan's UWMP; rather, their reporting represents subtotals of the regional total and should be considered as such for the purposes of determining reduced reliance on the Delta.

While the demands that Metropolitan's member agencies and their customers report in their UWMPs are a good reflection of the demands in their respective service areas, they do not adequately represent each water supplier's contributions to reduced reliance on the Delta. In order to calculate and report their reliance on water supplies from the Delta watershed, water suppliers that receive water from the Delta through other regional or wholesale water suppliers would need to determine the amount of Delta water that they receive from the regional or wholesale supplier. Two specific pieces of information are needed to accomplish this: first is the quantity of demands on the regional or wholesale water supplier that accurately reflect a supplier's contributions to reduced reliance on the Delta, and second is the quantity of a supplier's demands on the regional or wholesale water supplier that are met by supplies from the Delta watershed.

For water suppliers that make investments in regional projects or programs it may be infeasible to quantify their demands on the regional or wholesale water supplier in a way that accurately reflects their individual contributions to reduced reliance on the Delta. Due to the extensive, long-standing and successful implementation of regional demand management and local resource incentive programs in Metropolitan's service area, this infeasibility holds true for Metropolitan's members as well their customers. For Metropolitan's service area, reduced reliance on supplies from the Delta watershed can only be accurately accounted at the regional level, as is demonstrated in this analysis.

The following provides a summary of the near-term (2025) and long-term (2045) expected outcomes for Metropolitan's Delta reliance and regional self-reliance. The results show that as a region, Metropolitan and its members as well as their customers are measurably reducing reliance on the Delta and improving regional self-reliance, both as an amount of water used and as a percentage of water used.

Expected Outcomes for Regional Self-Reliance

- Near-term (2025) – Normal water year regional self-reliance is expected to increase by 813 TAF from the 2010 baseline; this represents an increase of almost 25 percent of 2025 normal water year retail demands (Table A.11-2).
- Long-term (2045) – Normal water year regional self-reliance is expected to increase by more than 1.28 MAF from the 2010 baseline, this represents an increase of more than 25 percent of 2045 normal water year retail demands (Table A.11-2).

Expected Outcomes for Reduced Reliance on Supplies from the Delta Watershed

- Near-term (2025) – Normal water year reliance on supplies from the Delta watershed decreased by 301 TAF from the 2010 baseline, this represents a decrease of 3 percent of 2025 normal water year retail demands (Table A.11-3).
- Long-term (2045) – Normal water year reliance on supplies from the Delta watershed decreased by 314 TAF from the 2010 baseline, this represents a decrease of just over 5 percent of 2045 normal water year retail demands (Table A.11-3).

A11.3 Demonstration of Reduced Reliance on the Delta

The methodology used to determine Metropolitan's reduced Delta reliance and improved regional self-reliance is consistent with the approach detailed in DWR's UWMP Guidebook Appendix C, including the use of narrative justifications for the accounting of supplies and the documentation of specific data sources. Some of the key assumptions underlying Metropolitan's demonstration of reduced reliance include:

- All data were obtained from the current 2020 UWMP or previously adopted UWMPs and represent average or normal water year conditions.
- All analyses were conducted at the service area level, and all data reflect the total contributions of Metropolitan and its members as well as their customers.
- No projects or programs that are described in the UWMPs as "Projects Under Development" were included in the accounting of supplies.

Baseline and Expected Outcomes

In order to calculate the expected outcomes for measurable reduction in Delta reliance and improved regional self-reliance, a baseline is needed to compare against. This analysis uses a normal water year representation of 2010 as the baseline, which is consistent with the approach described in the Guidebook Appendix C. Data for the 2010 baseline were taken from Metropolitan's 2005 UWMP as the UWMPs generally do not provide normal water year data for the year that they are adopted (i.e., 2005 UWMP forecasts begin in 2010, 2010 UWMP forecasts begin in 2015, and so on).

Consistent with the 2010 baseline data approach, the expected outcomes for reduced Delta reliance and improved regional self-reliance for 2015 and 2020 were taken from Metropolitan's 2010 and 2015 UWMPs respectively. Expected outcomes for 2025-2045 are from the current 2020 UWMP. Documentation of the specific data sources and assumptions are included in the discussions below.

Service Area Demands without Water Use Efficiency

In alignment with the Guidebook Appendix C, this analysis uses normal water year demands, rather than normal water year supplies to calculate expected outcomes in terms of the percentage of water used. Using normal water year demands serves as a proxy for the amount of supplies that would be used in a normal water year, which helps alleviate issues associated with how supply capability is presented to fulfill requirements of the Act versus how supplies might be accounted for to demonstrate consistency with WR P1.

Because WR P1 considers water use efficiency savings a source of water supply, water suppliers such as Metropolitan that explicitly calculate and report water use efficiency savings in their UWMP will need to make an adjustment to properly reflect normal water year demands in the calculation of reduced reliance. As explained in the Guidebook Appendix C, water use efficiency savings must be added back to the normal year demands to represent demands without water use efficiency savings accounted for; otherwise the effect of water use efficiency savings on regional self-reliance would be overestimated. Table A.11-1 shows the results of this adjustment for Metropolitan. Supporting narratives and documentation for all of the data shown in Table A.11-1 are provided below.

Table A.11-1
Demands without Water Use Efficiency Accounted For

Total Service Area Water Demands (Acre-Feet)	Baseline (2010)	2015	2020	2025	2030	2035	2040	2045
Service Area Demands with Water Use Efficiency Accounted For	4,628,000	4,563,000	4,163,000	3,763,000	3,821,000	3,893,000	3,936,000	3,985,000
Reported Water Use Efficiency	865,000	936,000	1,056,000	1,162,000	1,211,000	1,263,000	1,325,000	1,389,000
Service Area Demands without Water Use Efficiency Accounted For	**5,493,000**	**5,499,000**	**5,219,000**	**4,925,000**	**5,032,000**	**5,156,000**	**5,261,000**	**5,374,000**

Service Area Demands without Water Use Efficiency

The service area demands shown in Table A.11-1 represent the total retail water demands for Metropolitan's service area and include municipal and industrial demands, agricultural demands, seawater barrier demands, and storage replenishment demands. These demand types and the modeling methodologies used to calculate them are described in Section 2.2 and Appendix 1 of Metropolitan's UWMP.

Water Use Efficiency

The water use efficiency numbers shown in Table A.11-1 represent the total water use efficiency savings (conservation) for Metropolitan's region, including savings from active, code-based, price-effect and pre-1990 sources. These sources of water use efficiency and the methodologies used to calculate them are described in Section 2.2, Section 3.4, Section 3.7 and Appendix 1 of Metropolitan's UWMP.

The demand and water use efficiency data shown in Table A.11-1 were collected from the following sources:

- Baseline (2010) values – Metropolitan's 2005 UWMP, Table 2-6: Metropolitan Regional Water Demand Average Year
- 2015 values – Metropolitan's 2010 UWMP, Table 2-8: Metropolitan Regional Water Demands Average Year
- 2020 values – Metropolitan's 2015 UWMP, Table 2-3: Metropolitan Regional Water Demands Average Year
- 2025-2045 values – Metropolitan's 2020 UWMP, Table 2-3: Metropolitan Regional Water Demands Normal Water Year

Supplies Contributing to Regional Self-Reliance

For a covered action to demonstrate consistency with the Delta Plan, WR P1 subsection (c)(1)(C) states that water suppliers must report the expected outcomes for measurable improvement in regional self-reliance. Table A.11-2 shows expected outcomes for supplies contributing to regional self-reliance both in amount and as a percentage. The numbers shown in Table A.11-2 represent efforts to improve regional self-reliance for Metropolitan's entire service area and include the total contributions of Metropolitan and its members as well as their customers. Supporting narratives and documentation for the all of the data shown in Table A.11-2 are provided below.

The results shown in Table A.11-2 demonstrate that Metropolitan's service area is measurably improving its regional self-reliance. In the near-term (2025), the expected outcome for normal water year regional self-reliance increases by 747 TAF from the 2010 baseline; this represents an increase of about 23 percent of 2025 normal water year retail demands. In the long-term (2045), normal water year regional self-reliance is expected to increase by more than 1.2 MAF from the 2010 baseline; this represents an increase of 25 percent of 2045 normal water year retail demands.

Table A.11-2
Supplies Contributing to Regional Self-Reliance

Water Supplies Contributing to Regional Self-Reliance (Acre-Feet)	Baseline (2010)	2015	2020	2025	2030	2035	2040	2045
Water Use Efficiency	865,000	936,000	1,056,000	1,162,000	1,211,000	1,263,000	1,325,000	1,389,000
Water Recycling	316,000	348,000	436,000	550,000	613,000	687,000	698,000	706,000
Stormwater Capture and Use	100,000	103,000	110,000	80,000	82,000	82,000	82,000	82,000
Advanced Water Technologies	111,000	101,000	194,000	194,000	208,000	209,000	209,000	210,000
Conjunctive Use Projects	1,416,000	1,429,000	1,303,000	1,255,000	1,273,000	1,296,000	1,311,000	1,326,000
Local and Regional Water Supply and Storage Projects	252,000	224,000	261,000	257,000	257,000	258,000	258,000	258,000
Other Programs and Projects that Contribute to Regional Self-Reliance	875,000	1,250,000	1,200,000	1,250,000	1,250,000	1,250,000	1,250,000	1,250,000
Water Supplies Contributing to Regional Self-Reliance	**3,935,000**	**4,391,000**	**4,560,000**	**4,748,000**	**4,894,000**	**5,045,000**	**5,133,000**	**5,221,000**

Service Area Demands without Water Use Efficiency (Acre-Feet)	Baseline (2010)	2015	2020	2025	2030	2035	2040	2045
Service Area Demands without Water Use Efficiency Accounted For	5,493,000	5,499,000	5,219,000	4,925,000	5,032,000	5,156,000	5,261,000	5,374,000

Change in Regional Self Reliance (Acre-Feet)	Baseline (2010)	2015	2020	2025	2030	2035	2040	2045
Water Supplies Contributing to Regional Self-Reliance	3,935,000	4,391,000	4,560,000	4,748,000	4,894,000	5,045,000	5,133,000	5,221,000
Change in Supplies Contributing to Regional Self-Reliance	**NA**	**456,000**	**625,000**	**813,000**	**959,000**	**1,110,000**	**1,198,000**	**1,286,000**

Percent Change in Regional Self Reliance (As Percent of Demand w/out WUE)	Baseline (2010)	2015	2020	2025	2030	2035	2040	2045
Percent of Supplies Contributing to Regional Self-Reliance	71.6%	79.9%	87.4%	96.4%	97.3%	97.8%	97.6%	97.2%
Change in Percent of Supplies Contributing to Regional Self-Reliance	**NA**	**8.2%**	**15.7%**	**24.8%**	**25.6%**	**26.2%**	**25.9%**	**25.5%**

Water Use Efficiency

The water use efficiency information shown in Table A.11-2 is taken directly from Table A.11-1 above.

Water Recycling

The water recycling values shown in Table A.11-2 reflect the total recycled water production in Metropolitan's service area as described in Section 3.5 and Appendix 2 of Metropolitan's UWMP.

Stormwater Capture and Use

The stormwater capture and use data shown in Table A.11-2 include supplies from local surface water production as described in Section 1.4 and Appendix 2 of Metropolitan's UWMP.

These values do not include production from regional storage reservoirs; storage in these reservoirs is comprised of previously stored water from sources already reflected in Tables A.11-2 and A.11-3. These regional storage resources are generally used to provide additional regional self-reliance in dry years, which is not reflected in this normal water year analysis. The regional storage reservoirs and their yields are described in Section 3.6, Appendix 2 and Appendix 3 of Metropolitan's UWMP.

The stormwater capture and use values shown in Table A.11-2 also do not include stormwater capture that is used to recharge local groundwater basins. Stormwater capture for groundwater recharge supports production of groundwater in the region, and for the purposes of this analysis that production is already captured in Table A.11-2 under conjunctive use projects.

Advanced Water Technologies

The advanced water technologies data shown in Table A.11-2 include total groundwater recovery and seawater desalination production in Metropolitan's service area as described in Section 3.5 and Appendix 2 of Metropolitan's UWMP.

Conjunctive Use Projects

The values for conjunctive use projects shown in Table A.11-2 represent total groundwater production in the region as described in Section 1.4 and Appendix 2 of Metropolitan's UWMP.

The conjunctive use projects numbers shown in Table A.11-2 do not include production from regional groundwater conjunctive use programs. As described in the stormwater capture and use discussion above, these regional storage programs rely on previously stored water from sources already reflected in Tables A.11-2 and A.11-3 and are generally used to provide additional regional self-reliance in dry-years. The regional groundwater conjunctive use programs and their yields are described in Section 3.6 and Appendix 3.

Local and Regional Water Supply and Storage Programs

The data for local and regional water supply and storage programs shown in Table A.11-2 include supplies from the Los Angeles Aqueduct. This supply is described in Section 1.4 and Appendix 2 of Metropolitan's UWMP.

The local and regional supply numbers shown in Table A.11-2, except for "Other Programs and Projects that Contribute to Regional Self-Reliance" which is discussed below, were obtained from the following sources:

- Baseline (2010) values – Metropolitan's 2005 UWMP, Table 2-6: Metropolitan Regional Water Demand Average Year

- 2015 values – Metropolitan’s 2010 UWMP, Table 2-8: Metropolitan Regional Water Demands Average Year
- 2020 values – Metropolitan’s 2015 UWMP, Table 2-3: Metropolitan Regional Water Demands Average Year
- 2025-2045 values – Metropolitan’s 2020 UWMP, Table 2-3: Metropolitan Regional Water Demands Normal Water Year

Other Programs and Projects that Contribute to Regional Self-Reliance

Other programs and projects that contribute to regional self-reliance shown in Table A.11-2 include current programs from the Colorado River Aqueduct. Colorado River supplies include Metropolitan’s basic Colorado River apportionment, as well as supplies that result from existing and committed programs, including those from the IID-MWD Conservation Program, the implementation of the Quantification Settlement Agreement (QSA), related agreements, and the exchange agreement with SDCWA. Colorado River Aqueduct supplies and programs are described in Section 3.1 and Appendix 3 of Metropolitan’s UWMP.

The values shown in Table A.11-2 for other programs and projects that contribute to regional self-reliance come from the following sources:

- Baseline (2010) values – Metropolitan’s 2005 UWMP, Table A.3-7: Maximum Expected Colorado River Aqueduct Deliveries Year 2010 (Average Year)
- 2015 values – Metropolitan’s 2010 UWMP, Table A.3-7: Maximum Expected Colorado River Aqueduct Deliveries Year 2015 (Average Year)
- 2020 values – Metropolitan's 2015 UWMP, Table A.3-7: Maximum Expected Colorado River Aqueduct Deliveries Year 2020 (Average Year)
- 2025-2045 values – Metropolitan’s 2020 UWMP, Table A.3-7: Maximum Expected Colorado River Aqueduct Deliveries Years 2025, 2030, 2035, 2040, 2045 (Normal Water Year)

Reliance on Water Supplies from the Delta Watershed

In order for a covered action to demonstrate consistency with the Delta Plan, WR P1 subsection (c)(1)(C) requires that water suppliers report the expected outcomes for measurable reductions in supplies from the Delta watershed either as an amount or as a percentage. This analysis provides both calculations. Based on the methodology described in Guidebook Appendix C, and consistent with the approach of this analysis in not including projects under development, this accounting does not include any supplies from potential future covered actions. Table A.11-3 shows the expected outcomes for reliance on supplies from the Delta watershed for Metropolitan’s service area. Supporting narratives and documentation for the all of the data shown in Table A.11-3 are provided below.

The results shown in Table A.11-3 demonstrate that Metropolitan’s service area is measurably reducing its Delta reliance. In the near-term (2025), the expected outcome for normal water year reliance on supplies from the Delta watershed decreased by 301 TAF from the 2010 baseline; this represents a decrease of 3 percent of 2025 normal water year retail demands. In the long-term (2045), normal water year reliance on supplies from the Delta watershed decreased by 314 TAF from the 2010 baseline; this represents a decrease of just over 5 percent of 2045 normal water year retail demands.

Table A.11-3
Reliance on Water Supplies from the Delta Watershed

Water Supplies from the Delta Watershed (Acre-Feet)	Baseline (2010)	2015	2020	2025	2030	2035	2040	2045
CVP/SWP Contract Supplies	1,472,000	1,029,000	984,000	1,133,000	1,130,000	1,128,000	1,126,000	1,126,000
Delta/Delta Tributary Diversions	-	-	-	-	-	-	-	-
Transfers and Exchanges of Supplies from the Delta Watershed	20,000	44,000	91,000	58,000	52,000	52,000	52,000	52,000
Other Water Supplies from the Delta Watershed	-	-	-	-	-	-	-	-
Total Water Supplies from the Delta Watershed	**1,492,000**	**1,073,000**	**1,075,000**	**1,191,000**	**1,182,000**	**1,180,000**	**1,178,000**	**1,178,000**

Service Area Demands without Water Use Efficiency (Acre-Feet)	Baseline (2010)	2015	2020	2025	2030	2035	2040	2045
Service Area Demands without Water Use Efficiency Accounted For	5,493,000	5,499,000	5,219,000	4,925,000	5,032,000	5,156,000	5,261,000	5,374,000

Change in Supplies from the Delta Watershed (Acre-Feet)	Baseline (2010)	2015	2020	2025	2030	2035	2040	2045
Water Supplies from the Delta Watershed	1,492,000	1,073,000	1,075,000	1,191,000	1,182,000	1,180,000	1,178,000	1,178,000
Change in Supplies from the Delta Watershed	**NA**	**(419,000)**	**(417,000)**	**(301,000)**	**(310,000)**	**(312,000)**	**(314,000)**	**(314,000)**

Percent Change in Supplies from the Delta Watershed (As a Percent of Demand w/out WUE)	Baseline (2010)	2015	2020	2025	2030	2035	2040	2045
Percent of Supplies from the Delta Watershed	27.2%	19.5%	20.6%	24.2%	23.5%	22.9%	22.4%	21.9%
Change in Percent of Supplies from the Delta Watershed	**NA**	**-7.6%**	**-6.6%**	**-3.0%**	**-3.7%**	**-4.3%**	**-4.8%**	**-5.2%**

CVP/SWP Contract Supplies

The CVP/SWP contract supplies shown in Table A.11-3 include Metropolitan's SWP Table A and Article 21 supplies. These supplies are described in Section 3.2 and Appendix 3 of Metropolitan's UWMP.

The values shown in Table A.11-3 do not include Desert Water Agency/Coachella Valley Water District SWP contract supplies. These supplies are exchanged with Desert Water Agency and Coachella Valley Water District for an equal amount of Colorado River water, which is reflected in the Colorado River Aqueduct supplies shown in Table A.11-2. In addition, Desert Water Agency and Coachella Valley Water District should include their SWP contract supplies in their own accountings of reduced reliance. Additional information on these exchange agreements can be found in Section 3.2 and Appendix 3 of Metropolitan's UWMP.

These values also do not include supplies from San Luis Carryover storage or Central Valley storage programs because storage in these programs comprises previously stored water from sources already reflected in Table A.11-3. These storage programs are generally used to provide additional regional self-reliance in dry years, which is not reflected in this normal water year analysis. The Central Valley storage projects and their yields are described in Section 3.3, and Appendix 3. San Luis Carryover storage is described in Section 3.2 and Appendix 3.

Transfers and Exchanges of Supplies from the Delta Watershed

The transfers and exchanges of supplies from the Delta watershed shown in Table A.11-3 include supplies from the San Bernardino Valley MWD Program, Yuba River Accord Purchase Program, the San Gabriel Valley MWD Program, Irvine Ranch Water District Storage and Exchange Program, and other generic SWP and Central Valley transfers and exchanges. These programs are described in Section 3.2 and Appendix 3 of Metropolitan's UWMP.

Supplies from the Delta Watershed shown in Table A.11-3 are from the following sources:

- Baseline (2010) values – Metropolitan's 2005 UWMP, Table A.3-7: California Aqueduct Program Capabilities Year 2010 (Average Year)

- 2015 values – Metropolitan's 2010 UWMP, Table A.3-7: California Aqueduct Program Capabilities Year 2015 (Average Year)
- 2020 values – Metropolitan's 2015 UWMP, Table A.3-7: California Aqueduct Program Capabilities Year 2020 (Average Year)
- 2025-2045 values – Metropolitan's 2020 UWMP, Table A.3-7: California Aqueduct Program Capabilities Years 2025, 2030, 2035, 2040, 2045 (Normal Water Year)

A.11.4 UWMP Implementation

In addition to the analysis and documentation described above, WR P1 subsection (c)(1)(B) requires that all programs and projects included in the UWMP that are locally cost-effective and technically feasible, which reduce reliance on the Delta, are identified, evaluated, and implemented consistent with the implementation schedule. WR P1 (c)(1)(B) states that:

> *(B) Identified, evaluated, and commenced implementation, consistent with the implementation schedule set forth in the Plan, of all programs and projects included in the Plan that are locally cost effective and technically feasible which reduce reliance on the Delta*[.]

In accordance with Water Code Section 10631(f), water suppliers must already include in their UWMP a detailed description of expected future projects and programs that they may implement to increase the amount of water supply available to them in normal and single-dry water years and for a period of drought lasting five consecutive years. The UWMP description must also identify specific projects, include a description of the increase in water supply that is expected to be available from each project, and include an estimate regarding the implementation timeline for each project or program.

Section 3 of Metropolitan's UWMP summarizes the implementation plan and continued progress in developing a diversified water portfolio to meet the region's water needs.

Water Use Efficiency

The water use efficiency numbers used in this analysis include the total water use efficiency savings (conservation) for the service area, including savings from active, code-based, price-effect and pre-1990 savings. The specific water use efficiency programs and their implementation are described in Section 3.4 of Metropolitan's UWMP.

Water Recycling

The water recycling values used in this analysis reflect the total recycled water production in Metropolitan's service area. Water recycling programs and implementation are discussed in Section 3.5 of Metropolitan's UWMP. In addition, individual project-level details are provided in Appendix 5.

Stormwater Capture and Use

The stormwater capture and use data used in this analysis include supplies from local surface water production. Local surface water production and its implementation are discussed in Appendix 2 of Metropolitan's UWMP.

Advanced Water Technologies

The advanced water technologies data used in this analysis include total groundwater recovery and seawater desalination production in Metropolitan's service. Groundwater recovery and seawater desalination programs and implementation are described in Section 3.5 of Metropolitan's UWMP. In addition, individual project-level details are provided in Appendix 5.

Conjunctive Use Projects

The values for conjunctive use projects used in this analysis represent total groundwater production in the region. Groundwater production and its implementation are discussed in Appendix 2 of Metropolitan's UWMP.

Local and Regional Water Supply and Storage Programs

The data for local and regional water supply and storage programs shown this analysis include supplies from the Los Angeles Aqueduct. This program and its implementation are described in Appendix 2 of Metropolitan's UWMP.

Other Programs and Projects that Contribute to Regional Self-Reliance

Other programs and projects that contribute to regional self-reliance used in this analysis include current programs from the Colorado River Aqueduct. Colorado River supplies include Metropolitan's basic Colorado River apportionment, as well as supplies that result from existing and committed programs, including those from the IID-MWD Conservation Program, the implementation of the Quantification Settlement Agreement (QSA), related agreements, and the exchange agreement with SDCWA. Colorado River Aqueduct programs and their implementation are described in Section 3.1 and Appendix 3 of Metropolitan's UWMP.

CVP/SWP Contract Supplies

The CVP/SWP contract supplies shown in this analysis include Metropolitan's SWP Table A and Article 21 supplies. These supplies and their implementation are described in Section 3.2 and Appendix 3 of Metropolitan's UWMP.

Transfers and Exchanges of Supplies from the Delta Watershed

The transfers and exchanges of supplies from the Delta watershed shown in this analysis include supplies from the San Bernardino Valley MWD Program, Yuba River Accord Purchase Program, the San Gabriel Valley MWD Program, Irvine Ranch Water District Storage and Exchange Program, and other generic SWP and Central Valley transfers and exchanges. These programs and their implementation are described in Section 3.2 and Appendix 3 of Metropolitan's UWMP.

A.11.5 2015 UWMP Appendix 11

The information contained in this Appendix 11 is also intended to be a new Appendix 11 attached to Metropolitan's 2015 UWMP consistent with WR P1 subsection (c)(1)(C) (Cal. Code Regs. tit. 23, § 5003). Metropolitan provided notice of the availability of the draft 2020 UWMP (including this Appendix 11 which will also be a new Appendix 11 to its 2015 UWMP) and WSCP and the public hearing to consider adoption of both plans and Appendix 11 to the 2015 UWMP in accordance with CWC Sections 10621(b) and 10642, and Government Code Section 6066, and Chapter 17.5 (starting with Section 7290) of Division 7 of Title 1 of the Government Code. The public review drafts of the 2020 UWMP, Appendix 11 to the 2015 UWMP, and the WSCP were posted prominently on Metropolitan's website, mwdh2o.com, starting February 1, 2021, more than 60 days in advance of the public hearing on April 12, 2021. The notice of availability of the documents was sent to Metropolitan's member agencies, as well as cities and counties in Metropolitan's service area. In addition, a public notice advertising the public hearing in English and Spanish was published in 12 Southern California newspapers. The notification in English language newspapers was published on February 1 and 8, 2021. The notification was published on January 28-30, 2021 and February 1, 4-6, and 8, 2021 in Spanish language newspapers, satisfying the requirement for non-English language notification. Copies of: (1) the notification letter sent to the member agencies, cities and counties in Metropolitan's service area, and (2) the notice published in the newspapers are included in the 2020 UWMP Section 5. Thus, this Appendix 11 to Metropolitan's 2020 UWMP, which was adopted with Metropolitan's 2020 UWMP, will also be recognized and treated as Appendix 11 to Metropolitan's 2015 UWMP.

Metropolitan held the public hearing for the draft 2020 UWMP, draft Appendix 11 to the 2015 UWMP, and draft WSCP on April 12, 2021, at the Board's Water Planning and Stewardship Committee meeting, held online due to COVID-19 concerns. On May 11, 2021, Metropolitan's Board determined that the 2020 UWMP and the WSCP are consistent with the MWD Act and accurately represent the water resources plan for Metropolitan's service area. In addition, Metropolitan's Board determined that Appendix 11 to both the 2015 UWMP and the 2020 UWMP includes all of the elements described in Delta Plan Policy WR P1, Reduce Reliance on the Delta Through Improved Regional Water Self-Reliance (Cal. Code Regs. tit. 23, § 5003), which need to be included in a water supplier's UWMP to support a certification of consistency for a future covered action. As stated in Resolutions 9279, 9280, and 9281, the Board adopted the 2020 UWMP, Appendix 11 to the 2015 UWMP, and the WSCP and authorized their submittal to the State of California. Copies of Resolutions 9279, 9280, and 9281 are included in the 2020 UWMP Section 5, and Resolution 9281 for the WSCP is attached to the WSCP as Attachment C.

Appendix 12

DWR 2020 UWMP SUBMITTAL TABLES

Appendix 12
DWR 2020 UWMP SUBMITTAL TABLES

In fulfillment of California Water Code Sections, 10621(d) and 10644(a) and (b), Metropolitan's Final 2020 Urban Water Management Plan, Water Shortage Contingency Plan, and Appendix 11 Addendum to the 2015 Urban Water Management Plan were electronically submitted to the State of California through DWR's WUE Data Portal (https://wuedata.water.ca.gov/) in June 2021. This appendix contains the mandatory DWR 2020 UWMP Submittal Tables that were uploaded to the WUE data website.

Submittal Table 2-2: Plan Identification			
Select Only One	Type of Plan		Name of RUWMP or Regional Alliance *if applicable* (select from drop down list)
☑	Individual UWMP		
	☐	Water Supplier is also a member of a RUWMP	
	☐	Water Supplier is also a member of a Regional Alliance	
☐	Regional Urban Water Management Plan (RUWMP)		
NOTES:			

Submittal Table 2-3: Supplier Identification	
Type of Supplier (select one or both)	
☑	Supplier is a wholesaler
☐	Supplier is a retailer
Fiscal or Calendar Year (select one)	
☑	UWMP Tables are in calendar years
☐	UWMP Tables are in fiscal years
If using fiscal years provide month and date that the fiscal year begins (mm/dd)	
Units of measure used in UWMP * (select from drop down)	
Unit	AF
** Units of measure (AF, CCF, MG) must remain consistent throughout the UWMP as reported in Table 2-3.*	
NOTES:	

Submittal Table 2-4 Wholesale: Water Supplier Information Exchange (select one)	
☑	Supplier has informed more than 10 other water suppliers of water supplies available in accordance with Water Code Section 10631. Completion of the table below is optional. If not completed, include a list of the water suppliers that were informed.
Section 5 pp. 5-8 to 5-9	**Provide page number for location of the list.**
☐	Supplier has informed 10 or fewer other water suppliers of water supplies available in accordance with Water Code Section 10631. **Complete the table below.**
Water Supplier Name	
Add additional rows as needed	
NOTES: NOTES: See 2020 UWMP Sections 2 and 5 for discussion of Metropolitan's planning coordination, outreach, and notification (list provided in Section 5 Table 5-3 pp. 5-8 and 5-9).	

Submittal Table 3-1 Wholesale: Population - Current and Projected						
Population Served	2020	2025	2030	2035	2040	2045*(opt)*
	19,035,000	**20,089,000**	**20,634,000**	**21,145,000**	**21,610,000**	**22,026,000**
NOTES: See 2020 UWMP Appendix 1 Tabel A.1-2.						

Submittal Table 4-1 Wholesale: Demands for Potable and Non-Potable[1] Water - Actual			
Use Type	2020 Actual		
Drop down list May select each use multiple times These are the only use types that will be recognized by the WUE data online submittal tool	Additional Description (as needed)	Level of Treatment When Delivered Drop down list	Volume[2]
Add additional rows as needed			
Sales to other agencies		Drinking Water	789,218
Sales to other agencies		Raw Water	605,043
Losses			48,520
		TOTAL	1,442,781
[1] *Recycled water demands are NOT reported in this table. Recycled water demands are reported in Table 6-4.*			
[2] *Units of measure (AF, CCF, MG) must remain consistent throughout the UWMP as reported in Table 2-3.*			
NOTES: Sales to other agencies include Metropolitan deliveries to member and non-member agencies and deliveries from conjunctive use programs. Some of these deliveries are not revenue producing nor sales. Losses include evaporation losses from storage reservoirs and distribution system (2019 estimate). Water losses are both drinking and raw water.			

Submittal Table 4-2 Wholesale: Use for Potable and Raw Water [1] - Projected

Use Type	Additional Description (as needed)	Projected Water Use [2] Report To the Extent that Records are Available				
Drop down list May select each use multiple times These are the only Use Types that will be recognized by the WUEdata online submittal tool.		2025	2030	2035	2040	2045 (opt)
Add additional rows as needed						
Other		1,149,000	1,110,000	1,084,000	1,100,000	1,125,000
Exchanges to other agencies		278,000	278,000	278,000	278,000	278,000
	TOTAL	1,427,000	1,388,000	1,362,000	1,378,000	1,403,000

[1] *Recycled water demands are NOT reported in this table. Recycled water demands are reported in Table 6-4*

[2] *Units of measure (AF, CCF, MG) must remain consistent throughout the UWMP as reported in Table 2-3.*

NOTES: See 2020 UWMP detailed discussion in Section 2, Metropolitan's Regional Water Demands Table 2-3 for Normal Water Year, and Supply Capability and Projected Demands Table 2-6 for Normal Water Year (average of 1922 to 2017 historic hydrologies).

Submittal Table 4-3 Wholesale: Total Water Use (Potable and Non-Potable)

	2020	2025	2030	2035	2040	2045 (opt)
Potable and Raw Water From Tables 4-1W and 4-2W	1,442,781	1,427,000	1,388,000	1,362,000	1,378,000	1,403,000
Recycled Water Demand* From Table 6-4W	0	0	0	0	0	0
TOTAL WATER DEMAND	1,442,781	1,427,000	1,388,000	1,362,000	1,378,000	1,403,000

**Recycled water demand fields will be blank until Table 6-4 is complete.*

NOTES:

OPTIONAL Table 4-4 Wholesale: Last Five Years of Water Loss Audit Reporting

Reporting Period Start Date (mm/yyyy)	Volume of Water Loss [1,2]
01/2015	10,628
01/2016	8,545
01/2017	7,928
01/2018	4,991
01/2019	6,907

[1] *Taken from the field "Water Losses" (a combination of apparent losses and real losses) from the AWWA worksheet.*

[2] ***Units of measure (AF, CCF, MG)** must remain consistent throughout the UWMP as reported in Table 2-3.*

NOTES: See 2020 UWMP discussions in Section 2.6 and Appendix 7, and estimate of distribution system water losses in Tables A.7-1, A.7-2, A.7-3, A.7-4, and A.7-5.

Submittal Table 6-1 Wholesale: Groundwater Volume Pumped						
☑	Supplier does not pump groundwater. The supplier will not complete the table below.					
☐	All or part of the groundwater described below is desalinated.					
Groundwater Type	Location or Basin Name	2016*	2017*	2018*	2019*	2020*
Add additional rows as needed						
	TOTAL	0	0	0	0	0
**** Units of measure (AF, CCF, MG)** must remain consistent throughout the UWMP as reported in Table 2-3.*						
NOTES:						

Submittal Table 6-3 Wholesale: Wastewater Treatment and Discharge Within Service Area in 2020											
☑	Wholesale Supplier neither distributes nor provides supplemental treatment to recycled water. The Supplier will not complete the table below.										
							2020 volumes [1]				
Wastewater Treatment Plant Name	Discharge Location Name or Identifier	Discharge Location Description	Wastewater Discharge ID Number (optional) [2]	Method of Disposal *Drop down list*	Does This Plant Treat Wastewater Generated Outside the Service Area? *Drop down list*	Treatment Level *Drop down list*	Wastewater Treated	Discharged Treated Wastewater	Recycled Within Service Area	Recycled Outside of Service Area	Instream Flow Permit Requirement
Add additional rows as needed											
						Total	0	0	0	0	0
[1] **Units of measure (AF, CCF, MG)** must remain consistent throughout the UWMP as reported in Table 2-3. [2] If the **Wastewater Discharge ID Number** is not available to the UWMP preparer, access the SWRCB CIWQS regulated facility website at https://ciwqs.waterboards.ca.gov/ciwqs/readOnly/CiwqsReportServlet?inCommand=reset&reportName=RegulatedFacility											
NOTES:											

Submittal Table 6-4 Wholesale: Current and Projected Retailers Provided Recycled Water Within Service Area							
☑	Recycled water is not directly treated or distributed by the Supplier. The Supplier will not complete the table below.						
Name of Receiving Supplier or Direct Use by Wholesaler	Level of Treatment *Drop down list*	2020*	2025*	2030*	2035*	2040*	2045* *(opt)*
Add additional rows as needed							
	Total	0	0	0	0	0	0
*** Units of measure (AF, CCF, MG)** must remain consistent throughout the UWMP as reported in Table 2-3.							
NOTES:							

Submittal Table 6-5 Wholesale: 2015 UWMP Recycled Water Use Projection Compared to 2020 Actual		
☑	Recycled water was not used or distributed by the supplier in 2015, nor projected for use or distribution in 2020. The wholesale supplier will not complete the table below.	
Name of Receiving Supplier or Direct Use by Wholesaler	2015 Projection for 2020*	2020 Actual Use*
Add additional rows as needed		
Total	0	0
***Units of measure (AF, CCF, MG)** *must remain consistent throughout the UWMP as reported in Table 2-3.*		
NOTES: The 2015 UWMP Table 2-3 included projection for recycled water use in 2020 of 436 TAF under average hydrology. In 2020, the actual recycled water use (regional total within Metropolitan service area) is estimated at 441 TAF (excluding Santa Ana River baseflow), as discussed in this 2020 UWMP Section 3.5 on Table 3-14 p. 3-78 and Appendix 2 p. A.2-8. Regional total represents the projected production of projects by Metropolitan member agencies. Metropolitan's Regional Recycled Water Program is still a pilot project, with recent Board approval to proceed with environmental planning.		

Submittal Table 6-7 Wholesale: Expected Future Water Supply Projects or Programs						
☐	No expected future water supply projects or programs that provide a quantifiable increase to the agency's water supply. Supplier will not complete the table below.					
☑	Some or all of the supplier's future water supply projects or programs are not compatible with this table and are described in a narrative format.					
2020 UWMP Section 3 and Appendix 3	Provide page location of narrative in the UWMP					
Name of Future Projects or Programs	Joint Project with other suppliers?		Description *(if needed)*	Planned Implementation Year	Planned for Use in Year Type *Drop Down list*	Expected Increase in Water Supply to Supplier*
	Drop Down Menu	*If Yes, Supplier Name*				
Add additional rows as needed						
***Units of measure (AF, CCF, MG)** *must remain consistent throughout the UWMP as reported in Table 2-3.*						
NOTES: See 2020 UWMP Section 3 description of resources and program development for CRA, SWP, Central Valley/SWP storage and transfers programs, conservation, LRP (groundwater recovery, recycling, desalination), and groundwater. Also, see Appendix 3 detailed discussion of all supply programs and justification for supply projections.						

Submittal Table 6-8 Wholesale: Water Supplies — Actual				
Water Supply	Additional Detail on Water Supply	2020		
Drop down list May use each category multiple times.These are the only water supply categories that will be recognized by the WUEdata online submittal tool		Actual Volume*	Water Quality Drop Down List	Total Right or Safe Yield* (optional)
Add additional rows as needed				
Purchased or Imported Water		1,069,648	Other Non-Potable Water	
Supply from Storage		367,069	Other Non-Potable Water	
Transfers		6,064	Other Non-Potable Water	
	Total	1,442,781		0
*Units of measure (AF, CCF, MG) must remain consistent throughout the UWMP as reported in Table 2-3.				
NOTES: Actual volume of water reported in this table are raw water. The "Other Non-Potable Water" from the Water Quality column drop down list is the closest description to raw water.				

Submittal Table 6-9 Wholesale: Water Supplies — Projected											
Water Supply	Additional Detail on Water Supply	Projected Water Supply* Report To the Extent Practicable									
		2025		2030		2035		2040		2045 (opt)	
Drop-down list May use each category multiple times. These are the only water supply categories that will be recognized by the WUEdata online submittal tool		Reasonably Available Volume	Total Right or Safe Yield (optional)	Reasonably Available Volume	Total Right or Safe Yield (optional)	Reasonably Available Volume	Total Right or Safe Yield (optional)	Reasonably Available Volume	Total Right or Safe Yield (optional)	Reasonably Available Volume	Total Right or Safe Yield (optional)
Add additional rows as needed											
Other		3,912,000		3,906,000		3,903,000		3,901,000		3,898,000	
	Total	3,912,000	0	3,906,000	0	3,903,000	0	3,901,000	0	3,898,000	0
*Units of measure (AF, CCF, MG) must remain consistent throughout the UWMP as reported in Table 2-3.											
NOTES: See 2020 UWMP detailed discussion in Section 2 and Supply Capability and Projected Demands Table 2-6 for Normal Water Year (average of 1922-2017 hydrologies). Projected water supply includes capability of current and proposed programs.											

Submittal Table 7-1 Wholesale: Basis of Water Year Data (Reliability Assessment)			
Year Type	**Base Year** If not using a calendar year, type in the last year of the fiscal, water year, or range of years, for example, water year 1999-2000, use 2000	Available Supplies if Year Type Repeats	
		☑ Quantification of available supplies is not compatible with this table and is provided elsewhere in the UWMP. Location: 2020 UWMP Section 2 Tables 2-4, 2-5, 2-6, and Appendix 3.	
		☐ Quantification of available supplies is provided in this table as either volume only, percent only, or both.	
		Volume Available *	% of Average Supply
Average Year	1922-2017		100%
Single-Dry Year	1977		
Consecutive Dry Years 1st Year	1988		
Consecutive Dry Years 2nd Year	1989		
Consecutive Dry Years 3rd Year	1990		
Consecutive Dry Years 4th Year	1991		
Consecutive Dry Years 5th Year	1992		

Supplier may use multiple versions of Table 7-1 if different water sources have different base years and the supplier chooses to report the base years for each water source separately. If a supplier uses multiple versions of Table 7-1, in the "Note" section of each table, state that multiple versions of Table 7-1 are being used and identify the particular water source that is being reported in each table. Suppliers may create an additional worksheet for the additional tables.

***Units of measure (AF, CCF, MG)** must remain consistent throughout the UWMP as reported in Table 2-3.*

NOTES: See 2020 UWMP Section 2.3 discussion of sources of supply and water reliability assessment under normal water year, single dry year, and five consecutive drought years (summarized in Tables 2-4, 2-5, and 2-6). See Section 3 and Appendix 3 for a detailed discussion of all supply programs and justifications for supply projections. See Section 2 p. 2-7 for description, assumption, and basis of the three year types.

Submittal Table 7-2 Wholesale: Normal Year Supply and Demand Comparison

	2025	2030	2035	2040	2045 *(Opt)*
Supply totals *(autofill from Table 6-9)*	3,912,000	3,906,000	3,903,000	3,901,000	3,898,000
Demand totals *(autofill fm Table 4-3)*	1,427,000	1,388,000	1,362,000	1,378,000	1,403,000
Difference	2,485,000	2,518,000	2,541,000	2,523,000	2,495,000

NOTES: See 2020 UWMP detailed discussion in Section 2, and Supply Capabilities and reliability assessment in Table 2-6 for Normal Water Year condition (average of 1922-2017 historic hydrology).

Submittal Table 7-3 Wholesale: Single Dry Year Supply and Demand Comparison

	2025	2030	2035	2040	2045 (Opt)
Supply totals*	2,772,000	2,761,000	2,760,000	2,760,000	2,757,000
Demand totals*	1,544,000	1,500,000	1,473,000	1,496,000	1,525,000
Difference	1,228,000	1,261,000	1,287,000	1,264,000	1,232,000

***Units of measure (AF, CCF, MG)** must remain consistent throughout the UWMP as reported in Table 2-3.*

NOTES: See 2020 UWMP detailed discussion in Section 2, and Supply Capabilities and reliability assessment in Table 2-4 for Single Dry Year condition (repeat of 1977 hydrology).

Submittal Table 7-4 Wholesale: Multiple Dry Years Supply and Demand Comparison						
		2025*	2030*	2035*	2040*	2045* (Opt)
First year	Supply totals	2,178,800	2,219,000	2,241,000	2,263,000	2,239,000
	Demand totals	1,592,000	1,570,000	1,537,000	1,539,000	1,564,000
	Difference	586,800	649,000	704,000	724,000	675,000
Second year	Supply totals	2,178,800	2,219,000	2,241,000	2,263,000	2,239,000
	Demand totals	1,592,000	1,570,000	1,537,000	1,539,000	1,564,000
	Difference	586,800	649,000	704,000	724,000	675,000
Third year	Supply totals	2,178,800	2,219,000	2,241,000	2,263,000	2,239,000
	Demand totals	1,592,000	1,570,000	1,537,000	1,539,000	1,564,000
	Difference	586,800	649,000	704,000	724,000	675,000
Fourth year	Supply totals	2,178,800	2,219,000	2,241,000	2,263,000	2,239,000
	Demand totals	1,592,000	1,570,000	1,537,000	1,539,000	1,564,000
	Difference	586,800	649,000	704,000	724,000	675,000
Fifth year	Supply totals	2,178,800	2,219,000	2,241,000	2,263,000	2,239,000
	Demand totals	1,592,000	1,570,000	1,537,000	1,539,000	1,564,000
	Difference	586,800	649,000	704,000	724,000	675,000
Sixth year *(optional)*	Supply totals					
	Demand totals					
	Difference	0	0	0	0	0
***Units of measure (AF, CCF, MG) m** ust remain consistent throughout the UWMP as reported in Table 2-3.*						

NOTES: See 2020 UWMP detailed discussion in Section 2, and Supply Capabilities and reliability assessment in Table 2-5 for Five Consecutive Drought Year condition (repeat of 1988-1992 hydrology). Similar to the multiple dry-year reporting in past UWMPs, Metropolitan's reliability assessment for the five consecutive year drought is developed by simulating the five-year driest sequence leading to each of the fifth year reporting. This allows impacts of multiple consecutive years of droughts to be captured within the sequential accounting of Metropolitan's various supply program storage balance. The five consecutive years of supply and demand are then averaged and presented every five years rather than a year by-year display. Over the years, Metropolitan has developed numerous programs to increase its water supply capabilities, dry year supplies, and regional storage. These programs may be exercised in conjunction with effective demand management measures during drought years. Under this reliability planning, if a five consecutive year drought sequence was to repeat, Metropolitan could exercise similar supply augmentation and demand management options for each of the five drought years at the appropriate level to meet demands. This methodology best captures Metropolitan's complex demand and supply planning with appropriate flexibility.

Submittal Table 7-5: Five-Year Drought Risk Assessment Tables to address Water Code Section 10635(b)

2021	Total
Total Water Use	1,596,000
Total Supplies	1,164,000
Surplus/Shortfall w/o WSCP Action	(432,000)
Planned WSCP Actions (use reduction and supply augmentation)	
WSCP - supply augmentation benefit	432,000
WSCP - use reduction savings benefit	0
Revised Surplus/(shortfall)	0
Resulting % Use Reduction from WSCP action	0%

2022	Total
Total Water Use	1,669,000
Total Supplies	1,903,000
Surplus/Shortfall w/o WSCP Action	234,000
Planned WSCP Actions (use reduction and supply augmentation)	
WSCP - supply augmentation benefit	0
WSCP - use reduction savings benefit	0
Revised Surplus/(shortfall)	234,000
Resulting % Use Reduction from WSCP action	0%

2023	Total
Total Water Use	1,688,000
Total Supplies	1,300,000
Surplus/Shortfall w/o WSCP Action	(388,000)
Planned WSCP Actions (use reduction and supply augmentation)	
WSCP - supply augmentation benefit	388,000
WSCP - use reduction savings benefit	0
Revised Surplus/(shortfall)	0
Resulting % Use Reduction from WSCP action	0%

2024	Total
Total Water Use	1,491,000
Total Supplies	1,468,000
Surplus/Shortfall w/o WSCP Action	(23,000)
Planned WSCP Actions (use reduction and supply augmentation)	
WSCP - supply augmentation benefit	23,000
WSCP - use reduction savings benefit	0
Revised Surplus/(shortfall)	0
Resulting % Use Reduction from WSCP action	0%

2025	Total
Total Water Use	1,592,000
Total Supplies	1,369,000
Surplus/Shortfall w/o WSCP Action	(223,000)
Planned WSCP Actions (use reduction and supply augmentation)	
WSCP - supply augmentation benefit	223,000
WSCP - use reduction savings benefit	0
Revised Surplus/(shortfall)	0
Resulting % Use Reduction from WSCP action	0%

Note: See 2020 UWMP discussion in Section 2.4 Drought Risk Assessment and the supply augmentation actions that may be exercised to meet demands through 2025.

Submittal Table 8-1 Water Shortage Contingency Plan Levels		
Shortage Level	**Percent Shortage Range**	**Shortage Response Actions** *(Narrative description)*
1	Up to 10%	Shortage response actions will be customized to meet the circumstances for the particular shortage. Response actions may include a combination of supply augmentation from flexible supplies and dry year storage, demand response actions, and operational measures.
2	Up to 20%	Shortage response actions will be customized to meet the circumstances for the particular shortage. Response actions may include a combination of supply augmentation from flexible supplies and dry year storage, demand response actions, and operational measures.
3	Up to 30%	Shortage response actions will be customized to meet the circumstances for the particular shortage. Response actions may include a combination of supply augmentation from flexible supplies and dry year storage, demand response actions, and operational measures.
4	Up to 40%	Shortage response actions will be customized to meet the circumstances for the particular shortage. Response actions may include a combination of supply augmentation from flexible supplies and dry year storage, demand response actions, and operational measures.
5	Up to 50%	Shortage response actions will be customized to meet the circumstances for the particular shortage. Response actions may include a combination of supply augmentation from flexible supplies and dry year storage, demand response actions, and operational measures.
6	>50%	Shortage response actions will be customized to meet the circumstances for the particular shortage. Response actions may include a combination of supply augmentation from flexible supplies and dry year storage, demand response actions, operational measures, and emergency storage if needed.
NOTES: Actions taken will be based on resource and operational conditions throughout the year. To determine specific actions that would be taken at each level, Metropolitan will evaluate circumstances including cost, timing, distribution needs and capabilities, and other variables that include SWP allocation, Colorado River conditions, take capacities, and storage balances. See Table A.4-5 Shortage Stages and Response Actions from Appendix 4: Water Shortage Contingency Plan.		

Submittal Table 8-2: Demand Reduction Actions				
Shortage Level	Demand Reduction Actions ***Drop down list*** *These are the only categories that will be accepted by the WUEdata online submittal tool. Select those that apply.*	How much is this going to reduce the shortage gap? *Include units used (volume type or percentage)*	Additional Explanation or Reference *(optional)*	Penalty, Charge, or Other Enforcement? ***For Retail Suppliers Only*** *Drop Down List*
Add additional rows as needed				
1 to 6	Expand Public Information Campaign	Range between 160,000 to 320,000 acre-feet	Assumed range of between 5% and 10% effectiveness in demand reduction realized at the wholesale level, using a hypothetical single dry year assessment of wholesale demand within the 2020 Urban Water Management Plan (2025 single-dry year). Based on assumptions of service area retail M&I demand of 4.379 MAF and up to 20 percent of retail demands could be reduced if a successful media campaign reached and influenced the entire service area population (source: American Water Works Association. 2019. Manual of Water Supply Practices – M60, Second Edition: Drought Preparedness and Response. p. 35)	
1 to 6	Other	Up to 900,000 acre-feet	Water Supply Allocation Plan (WSAP) allocates Metropolitan's wholesale water supplies among its member agencies. The WSAP is designed to reduce demands by up to approximately 50 percent of the WSAP's calculated base demand. Up to 900,000 AF of savings is based on a hypothetical WSAP base demand of 1.8 MAF. Actual reductions and base demands are based on a formula that includes various factors such as actual local supply production, population growth, and conservation.	
NOTES: Total estimated savings potential from differerent Demand Reducation Actions are nonadditive. Savings potential from voluntary actions overlaps with savings from supply allocations.				

Submittal Table 8-3: Supply Augmentation and Other Actions			
Shortage Level	Supply Augmentation Methods and Other Actions by Water Supplier *Drop down list* *These are the only categories that will be accepted by the WUEdata online submittal tool*	How much is this going to reduce the shortage gap? *Include units used (volume type or percentage)*	Additional Explanation or Reference *(optional)*
Add additional rows as needed			
1 to 6	Transfers	Up to 64,000 acre-feet	Based on a hypothetical 2025 single dry year assessment within the 2020 Urban Water Management Plan. See Table 2-1 in the 2020 UWMP.
1 to 6	Other Actions (describe)	Up to 1,714,000 acre-feet	Dry year storage. Based on a hypothetical 2025 single dry year assessment within the 2020 Urban Water Management Plan.
6	Stored Emergency Supply	Up to 750,000 acre-feet	Based on Metropolitan's Emergency Storage Objective, set at 750,000 AF. Emergency storage represents water Metropolitan reservees for the region for use in the event of supply interruptions from earthquakes or similar emergencies.
NOTES:			

Submittal Table 10-1 Wholesale: Notification to Cities and Counties (select one)		
☑	Supplier has notified more than 10 cities or counties in accordance with Water Code Sections 10621 (b) and 10642. **Completion of the table below is not required. Provide a separate list of the cities and counties that were notified.**	
2020 UWMP Section 5 Table 5-3	Provide the page or location of this list in the UWMP.	
☐	Supplier has notified 10 or fewer cities or counties. **Complete the table below.**	
City Name	60 Day Notice	Notice of Public Hearing
Add additional rows as needed		
County Name *Drop Down List*	60 Day Notice	Notice of Public Hearing
Add additional rows as needed		
NOTES: See 2020 UWMP Section 5 discussion on Metropolitan's notification to cities and counties (list provided in Table 5-3). Metropolitan sent a total of 195 notification letters to cities, counties, and member agencies within its service area.

Section 1: Introduction/Lay Person Description

1.1 Overview

This document presents the 2020 Urban Water Management Plan (UWMP, Plan) for the Inland Empire Utilities Agency (IEUA or Agency) wholesale water service area. This section describes the general purpose of the Plan, discusses Plan implementation, and provides general information about IEUA and service area characteristics.

The State of California mandates that all urban water suppliers within the state prepare an UWMP. Detailed information on what must be included in these plans, as well as whom must complete them can be found in California Water Code (CWC) sections 10610 through 10657. According to the Urban Water Management Planning Act (UWMP Act) of 1983, an urban water supplier is defined as a supplier, either public or private, that provides water for municipal purposes either directly or indirectly to more than 3,000 customers or supplies more than 3,000 acre-feet (AF) annually. Urban water suppliers are required to prepare, adopt, and file an UWMP with the California Department of Water Resources (DWR) every 5 years. The 2020 UWMP updates are due to DWR by July 1, 2021.

1.2 Purpose

An UWMP is a planning tool that generally guides the actions of urban water suppliers. It provides managers and the public with a broad perspective on a number of water supply issues. It is not a substitute for project-specific planning documents, nor was it intended to be when mandated by the State Legislature. For example, the Legislature mandated that a plan include a section which "…describes the opportunities for exchanges or water transfers on a short-term or long-term basis." [Wat. Code, § 10631, subd. (d)]. The identification of such opportunities and the inclusion of those opportunities in a plan's general water service reliability analysis neither commits an urban water supplier to pursue a particular water exchange/transfer opportunity, nor precludes it from exploring exchange/transfer opportunities never identified in its plan. Before an urban water supplier is able to implement any potential future sources of water supply identified in a plan, detailed project plans are prepared and approved, financial and operational plans are developed, and all required environmental analysis is completed.

"A plan is intended to function as a planning tool to guide broad-perspective decision making by the management of water suppliers." [Sonoma County Water Coalition v. Sonoma County Water Agency (2010) 189 Cal. App. 4th 33, 39.] It should not be viewed as an exact blueprint for supply and demand management. Water management in California is not a matter of certainty and planning projections may change in response to a number of factors. "[L]ong-term water planning involves expectations and not certainties. Our Supreme Court has recognized the uncertainties inherent in long-term land use and water planning and observed that the generalized information required . . . in the early stages of the planning process are replaced by firm assurances of water supplies at later stages." (Id., at 41.) From this perspective, it is appropriate to look at the UWMP as a general planning framework, not a specific action plan. It is an effort to generally answer a series of planning questions such as:

- What are the potential sources of supply and what amounts are estimated to be available from them?
- What is the projected demand, given a reasonable set of assumptions about growth and implementation of water management practices?
- How do the projected supply and demands compare and relate to each other?

Using these "framework" questions and resulting answers, the implementing agency will pursue feasible and cost-effective options and opportunities to develop long-term supplies and sustainably meet demands.

Water suppliers can explore enhancing basic supplies from traditional sources such as local groundwater and imported water, as well as other options. These include groundwater extraction, water exchanges and transfers, water conservation, recycling, brackish water desalination, and water banking/conjunctive use. Additional specific planning efforts may be undertaken in regard to each option, involving detailed evaluations of how each option would fit into the overall supply/demand framework, potential environmental impacts, and how each option would affect customers.

The UWMP Act requires preparation of a plan that, among other things:

- Accomplishes water supply planning over a 20-year period in 5-year increments. (IEUA is going beyond the requirements of the Act by developing a plan which spans 25 years.)
- Identifies and quantifies existing and projected water supply opportunities, including recycled water, for existing and future demands, in normal, single-dry, and multiple-dry years.
- Implements conservation and efficient use of urban water supplies.

Additionally, Senate Bill (SB) 7 of Special Extended Session 7 (SBX7-7) was signed into law in November 2009, which calls for progress towards a 20 percent (%) reduction in per capita water use statewide by 2020. SBX7-7, otherwise referred to as the Water Conservation Act of 2009, requires each urban retail water supplier to develop and report a water use target in its 2010 UWMP, and to develop and report an interim 2015 water use target, baseline daily per capita use, and 2020 compliance daily per capita use, along with the basis for determining those estimates. Beginning in 2016, retail water suppliers were required to comply with the water conservation requirements in SBX7-7 in order to be eligible for State water grants or loans. Water suppliers have the ability to revisit the SBX7-7 baseline and water use targets determined in the 2010 UWMPs and update them in the 2020 UWMP.

In addition to the relatively new requirements of SBX7-7, a number of other changes to the Water Code have been enacted since 2010 which apply to the preparation of the 2020 Plan. These changes include:

- UWMP Submittal Date: 2020 UWMP updates must be adopted and submitted to DWR by July 1, 2021.
- Reporting on Compliance with SBX7-7 Targets: The 2020 UWMP will be required to document compliance with the 20% reduction described in the 20 by 2020 Water Conservation Plan, and a comparison of actual water use against the target.
- 5-year Drought Risk Assessment: In past UWMPs, suppliers were to conduct a drought risk assessment assuming a period of drought lasting 3 consecutive years. This requirement has changed, and suppliers must now assess a drought lasting 5 years.
- Sustainable Groundwater Management Act (AB 1739, SB1168, and SB1319): Requires UWMPs to show consistency with Groundwater Sustainability Plan (GSP) supply protections, if applicable.
- Seismic Risk Assessment (SB 664): If applicable, requires an urban water supplier to include within its plan a seismic risk assessment and mitigation plan to assess the vulnerability of each of the various facilities of a water system and mitigate those vulnerabilities.
- Water Shortage Contingency Plan (WSCP) Updates: State requirements call for an update to the existing WSCP and that it be formally adopted as a stand-alone plan. The WSCP must be updated in parallel with the UWMP.
- Making Water Conservation a California Way of Life [Assembly Bill (AB) 1668 and SB 606]: Regulations targeting indoor water demand and affecting the need for additional water use efficiency in the State.
- Annual Water Supply and Demand Assessments: Assessments will be required, starting June 2022, and the process to do the assessment must be described in the 2020 UWMP.
- Items optional in the past, but now required, include: calculating the energy intensity of water, incorporation of land use changes in demand forecasting, and estimating water savings from codes and standards.

A checklist to ensure compliance of this Plan with the UWMP Act requirements is provided in Appendix A.

1.3 IEUA UWMP Preparation

In accordance with the CWC, urban water suppliers with 3,000 or more service connections, or supplying 3,000 or more acre-feet of water per year (AFY), are required to prepare a UWMP every 5 years. The 2020 UWMP must be approved and submitted to DWR by July 1, 2021.

This 2020 UWMP is an update of IEUA's portion of the IEUA and Water Facilities Authority (WFA) 2015 UWMP. In 2015, IEUA prepared a Regional UWMP (RUWMP) in collaboration with WFA, a wholesale supplier of imported water (State Water Project water) purchased from Metropolitan Water District of Southern California (MWD or Metropolitan) via IEUA. WFA provides services to five retail agencies that are encompassed within IEUA's service area, including the Cities of Chino, Chino Hills, Ontario, Upland, and Monte Vista Water District (MVWD). This 2020 Wholesale UWMP was not prepared as an RUWMP and was developed by IEUA individually in coordination with its retail agencies.

While this 2020 UWMP provides water demand, water supply, and supply reliability assessment for the entire IEUA region, all requirements of the CWC for each of IEUA's retail agencies will be met through each retail agency's individual 2020 UWMP. Additionally, as reported in the 2015 UWMP, IEUA formed a regional alliance consisting of seven of its retail agencies (all retail agencies excluding SAWCo and WVWD) to comply with SB x7-7 goals. The regional alliance will also allow IEUA and its retail agencies to continue to cooperatively participate in developing Water Use Efficiency (WUE) programs and meeting water conservation goals. Table 1-1 identifies this as an individual UWMP prepared by IEUA. Table 1-2 indicates that IEUA is a wholesale supplier.

A water supplier may report on a fiscal year or calendar year basis but must clearly state in its UWMP the type of year that is used for reporting. The type of year should remain consistent throughout the Plan. All data in this Plan is reported in fiscal years and volumes are reported in AF, as shown in Table 1-2.

Table 1-1: DWR Plan Identification (DWR Table 2-2)

1.3.1 Relationship to Other Planning by IEUA

IEUA has developed plans to expand and provide an adequate water supply for its retail agencies. The plans include:

- 2020 Water Use Efficiency Business Plan (WUEBP) – The WUEBP is updated every 5 years with input from IEUA's regional WUE partners to increase regional sustainability through using water more efficiently, eliminating water waste, and drought-proofing the region through increased use of recycled water, groundwater, stormwater, and other local water supplies. The 2020 WUEBP is currently in development and will provide updated analyses and recommended methods to improve efficiency and achieve regional sustainability.

- 2020 Regional Drought Contingency Plan (DCP) – The DCP was developed to define regional shortage conditions, identify vulnerabilities, build resiliency through mitigation and response actions, and facilitate consistent communication within the service area while ensuring equity and fairness. The DCP was also developed to support the needs of the WSCP, a requirement of this 2020 UWMP.

- 2015 Integrated Water Resources Plan (IRP) and 2020 Modeling – The IRP and modeling was conducted to support regional and local water supply planning by assessing water supply vulnerabilities and evaluate collaborative infrastructure and management strategies to increase water supply resiliency in the region.

- 2018 Climate Change Action Plan (CCAP) – The CCAP was developed to identify local impacts of climate change and lay the groundwork for projects and management practices that will allow IEUA to continue providing reliable services to the region while remaining a steward to the environment.

- 2015 Recycled Water Program Strategy (RWPS) Report – The purpose of the RWPS Report was to update recycled water Direct Use demand projections and changes to IEUA's groundwater recharge program, as well as investigate operational changes to the recycled water conveyance system as a result of increasing reuse of the recycled water supply availability.

- 2015 Energy Management Plan (EMP) – The EMP analyzed historical energy usage, established a current energy and Greenhouse Gas emissions baseline, forecasted future demand, examined procurement strategies, and explored measures to ease IEUA's energy load while cultivating a reliable and sustainable energy infrastructure across its facilities.

1.3.2 Relationship to Water Shortage Contingency Plan

Several elements of the 2020 UWMP, especially Section 7, Reliability Planning, and Section 8, Demand Management Measures, are coordinated with the WSCP which is a separate document. The WSCP is a detailed plan of how IEUA intends to act in the case of water shortage conditions. The WSCP identifies specific response actions that align with six standard water shortage levels. The information in the WSCP was prepared using the information developed in the 2020 DCP. The 2020 WSCP is included in Appendix B.

1.4 Structure and Organization of the Plan

The content presented in this UWMP corresponds to the outline of the Act, specifically Article 2, Contents of Plans, which correspond to the CWC Sections 10631, 10632, and 10633. The organization of the report differs slightly from the DWR UWMP Guidebook's organization in order to reflect the unique characteristics of IEUA's systems, as well as to be as consistent as possible with IEUA's IRP and Water Use Efficiency Business Plan. This UWMP is organized as follows:

- Section 1 – Introduction
- Section 2 – Water Demands
- Section 3 – SBX7-7 Baseline and Targets
- Section 4 – Water Resources
- Section 5 – Recycled Water and Reuse
- Section 6 – Water Quality
- Section 7 – Reliability Planning
- Section 8 – Demand Management Measures
- Section 9 – Energy Intensity Reporting
- Section 10 – Seismic Risk Assessment

The UWMP Checklist has been completed, which identifies the location of the UWMP Act requirements in this UWMP and is included in Appendix A.

1.5 System Description

IEUA was formed as a municipal water district by popular vote of its residents in June 1950 to become a member agency of MWD for the purpose of importing water to its retail agencies. IEUA has significantly expanded its water and wastewater utility services since 1950 to also include wastewater treatment, recycled water production and distribution, co-composting of green waste and municipal biosolids, desalination of brackish water, and disposal of non-reclaimable industrial wastewater and brine. IEUA is governed by a five-member Board of Directors. Each Director is publicly elected for a 4-year term and represents one of the five divisions:

- Division 1 – Upland, Montclair, portion of Ontario, and portion of Rancho Cucamonga.
- Division 2 – Ontario, portion of Chino, and portion of Fontana.

- Division 3 – Chino and Chino Hills.
- Division 4 – Fontana, portion of Rialto, and portion of Bloomington.
- Division 5 – Rancho Cucamonga and portion of Fontana.

2021 IEUA Board members are:

- Marco Tule – Director, Division 1.
- Paul Hofer – Director, Division 2.
- Steven Elie – Secretary/Treasurer, Division 3.
- Jasmin Hall – President, Division 4.
- Michael Camacho – Vice President, Division 5.

IEUA owns and operates four regional water recycling plants in its service area: Regional Water Recycling Plant Number (No.) 1, Regional Water Recycling Plant No. 4, Regional Water Recycling Plant No. 5, and the Carbon Canyon Water Recycling Facility (RP-1, RP-4, RP-5, and the CCWRF). IEUA's regional recycled water plants produce disinfected, tertiary treated recycled water in compliance with California's Title 22 regulations. Wastewater is collected with regional wastewater interceptors and two non-reclaimable wastewater pipeline systems. Biosolids produced at the water recycling plants are handled by three facilities: RP-1 Solids Handling Facility, Regional Water Recycling Plant No. 2 (RP-2) Solids Handling Facility, and the Inland Empire Regional Composting Facility. IEUA owns and operates sewer lines and recycled water pipelines. The recycled water systems include pump stations, reservoirs, and pressure regulating stations to serve numerous pressure zones. IEUA also operates groundwater recharge facilities in cooperation with the Chino Basin Watermaster (CBWM or Watermaster), San Bernardino County Flood Control District (SBCFCD), and the Chino Basin Water Conservation District. The Chino I Desalter is managed by IEUA under an agreement with the Chino Basin Desalter Authority (CDA). IEUA does not own or operate drinking water facilities.

1.5.1 Service Area

IEUA provides a number of services for the southwestern section of San Bernardino County in the Santa Ana River Watershed. The IEUA service area almost entirely overlies the Chino Groundwater Basin (Chino Basin). The 242-square mile service area encompasses the Chino Basin which consists of a relatively flat alluvial valley from east to west and slopes from north to south at a 1 to 2% grade. Valley elevation ranges from about 2,000 feet above sea level in the foothills below the San Gabriel Mountains to about 500 feet near Prado Dam. Figure 1 shows the IEUA service area and its retail agencies.

IEUA's service area population has grown quickly in the past decade and is expected to increase in the future. The region's growth underlies the need for careful water resources planning and management to ensure adequate water supplies and address water quality challenges.

Figure 1

1.5.2 Retail Agencies

The IEUA service area consists of the cities of Chino, Chino Hills, Montclair, Upland, Ontario, Rancho Cucamonga, and Fontana, and unincorporated areas within San Bernardino County. There are nine retail water agencies within IEUA's service area which are described in Table 1-3. Two of IEUA's retail water agencies, (Fontana Water Company (FWC) and Cucamonga Valley Water District (CVWD)) purchase untreated water directly from IEUA and provide their own treatment. Five of IEUA's retail water agencies purchase treated water from WFA. WFA purchases untreated imported water from IEUA, treats and delivers the water to the cities of Chino, Chino Hills, Ontario, Upland, and MVWD. IEUA also provides wastewater services to seven agencies including the cities of Chino, Chino Hills, Fontana, Montclair, Ontario, Upland, and CVWD in the city of Rancho Cucamonga.

Table 1-3: IEUA Retail Agencies

Agency Name	Description
City of Chino	The City of Chino serves water to a population of approximately 74,000 in the City and some unincorporated areas in San Bernardino County.
City of Chino Hills	The City of Chino Hills provides water to a population of approximately 77,600 in the City within its 46 square mile service area that also includes small portions of Chino and Pomona.
Cucamonga Valley Water District	CVWD is a special district that provides water to approximately 200,460 residents within a 47-square mile area comprised mainly of the City of Rancho Cucamonga. CVWD also provides water to small portions of the cities of Upland, Ontario, Fontana, and unincorporated areas of San Bernardino County.
Fontana Water Company	Fontana Water Company is a retail investor-owned utility company that provides water to approximately 215,500 residents mainly in the City of Fontana, and also serves portions of the cities of Rancho Cucamonga and Rialto, outside the IEUA service area.
Monte Vista Water District	MVWD is a county water district that provides retail water services to a population of approximately 54,200 in the City of Montclair, portions of the City of Chino, and unincorporated areas of San Bernardino County between Chino, Ontario, and Pomona. MVWD is also a wholesale water supplier to the City of Chino Hills, providing up to 21 MGD of water.
City of Ontario	The City of Ontario supplies water to a population of approximately 168,780 in the city and some unincorporated areas of San Bernardino County. The City of Ontario also serves a small portion of the City of Rancho Cucamonga.
San Antonio Water Company	SAWCo is a mutual water company organized as a private non-profit corporation, with more than 70% of shares owned by municipalities. SAWCo wholesales surface water from San Antonio Creek and potable groundwater to Upland, Ontario, and irrigation customers.
City of Upland	The City of Upland encompasses 15 square miles and serves water to approximately 75,790 people.
West Valley Water District	WVWD is a retail water agency serving over 80,000 residents, some of which fall into an overlapping service area with IEUA. Through an assistance agreement, WVWD has the potential to receive imported water for up to 1,500 AFY through San Bernardino Valley Municipal Water District and MWD during supply outages, emergencies, or loss of local water supply through December 2035.

1.6 Population

The Southern California Association of Governments (SCAG) conducts a forecast process every 4 years to project growth in employment, population, and households at the regional, county, jurisdictional, and sub-jurisdictional levels for use in its Regional Transportation Plan/Sustainable Communities Strategy (RTP/SCS) and other planning documents. The forecasting process includes a review of US Census Bureau and California Department of Finance projections, development of key input assumptions, and meetings with all 197 local jurisdictions one-on-one to review the draft growth forecast. The growth forecast for population, household, and employment are developed for the years 2020, 2030, 2035, and 2045. The preliminary range of growth figures are produced first at the county level and then refined to smaller areas, called city and transportation analysis zones (TAZs), which are then released to local jurisdictions for comments and input. Once the growth forecasts for these TAZs are finalized, they are adopted by the Regional Council.

The 2020 SCAG RTP/SCS data and associated TAZs for San Bernardino County were obtained and used to calculate the current and projected population within IEUA's service area. A geospatial analysis was used to identify the TAZs within the IEUA service area and the population associated with each of these zones was summed to find the total population within IEUA's service areas for the years provided by SCAG. It should be noted that the FWC is only partially within the service area and only the population within IEUA's service boundary is considered in this UWMP. For 2025 and 2040, the population value was interpolated between the years provided before and after.

From these calculations, IEUA's service area currently serves a population of approximately 906,046 in 2020 and has an expected growth rate of approximately 0.90% per year. With this growth rate, IEUA's service area is expected to reach a population of 1,119,568 in 2045. Table 1-4 shows the projected population for every 5 years from 2020 through 2045. Table 1-4 is equivalent to DWR Table 3-1; all tables within the Plan that are DWR Standardized Tables have the DWR Table number in parentheses in the title. All completed DWR Standardized Tables are included in Appendix C.

Table 1-4: IEUA Population – Current and Projected (DWR Table 3-1)

	2020	2025	2030	2035	2040	2045
Population Served	906,046	945,849	987,401	1,031,771	1,074,773	1,119,568

Note: Population projections calculated using the 2020 Southern California Association of Governments population forecast.

1.7 Demographics and Socioeconomics

Approximately 25% of the IEUA service area population is considered a designated disadvantaged community (DAC) based on the American Community Survey Median Household Income (MHI) data. Census tracts are determined to be disadvantaged when the average household income is 80% or less than statewide median household income. The city of Montclair is a DAC, as is a large portion of the FWC's service area. There are also additional census tract areas that are designated as disadvantaged communities based on the MHI throughout the service area, primarily between HWY 10 and Mission Boulevard in the cities of Ontario and Montclair and between HWY 10 and HWY 66 in Rancho Cucamonga and Upland. The disadvantaged communities in the region are shown on Figure 2.

1.8 COVID-19 Impacts

As with most water service agencies in the state of California, the COVID-19 pandemic beginning in fiscal year 19/20 period impacted IEUA and its service area's operations. Transitions were made to remote or virtual activities where possible, and some capital improvement projects experienced delays until proper safety attire, such as masks, could be secured to ensure work could be continued safely. Some in-person public outreach and education events were cancelled. In addition, IEUA deferred its equivalent service unit (EDU) rate for 12 months and held water connection fees constant to compensate for the economic downturn and job loss in its service area. On May 6, 2020, the IEUA Board voted to defer the increase in sewer EDU rates established in Resolution No. 2019-11-2; the sewer EDU rate increase will be deferred 12 months, until July 1, 2021. IEUA held water connection fees constant from fiscal year 19/20 to fiscal year 20/21 as outlined in Resolution No. 2020-7-11. IEUA remains considerate of the continuation of the ongoing impacts of the pandemic and how it may impact future activities and operations.

1.9 Land Use in the Service Area

When IEUA was formed in 1950, its service area was primarily field crops, citrus, and vineyards with a total urban area land use of less than 8%. Since 1950, urban areas have expanded significantly and replaced most agricultural land in the northern and central portions of the Chino Basin. The conversion of agricultural land to urban development is anticipated to continue within the Chino Basin.

SCAG's 2020 RTP/SCS includes land use information. The SCAG worked with the region's 197 local jurisdictions to refine their land use dataset that was drafted in 2016. The most recent update was finalized on April 29, 2020. The land use dataset includes general plan land use, specific plan land use, zoning code, and existing land use. Figure 3 shows the land use code present in the IEUA service area. The majority of the service area is comprised of single family residential, industrial, and commercial areas. There are also large areas of open space in the service area, such as the Chino Hills State Park.

The 2015 Land Use Based Demand Model evaluated the existing and planned land uses within the service area out to 2040. The future land uses were calculated based on the general plans for each city in the service area using city spheres of influence as boundaries to prevent overlap. Residential land use is expected to have the largest growth, approximately 31% by 2040. Medium, high, and very high-density residential land uses are projected to increase more than low and very low-density residential land use. Industrial land use is projected to grow at 20%, while vacant land will decrease 98%and agriculture use will decrease by 96%.

1.10 Climate

IEUA is located within the South Coast Air Basin (SCAB) that encompasses all of Orange County and the urban areas of Los Angeles, San Bernardino, and Riverside counties. The SCAB climate is characterized as "Mediterranean" with a semi-arid environment with mild winters, warm summers, and moderate rainfall. The average annual rainfall in the IEUA water service area is approximately 15 inches, most of which occurs during the winter months.

Temperatures range in average from 41 to 67 degrees Fahrenheit (°F) during the winter and from 60 to 90°F degrees during the summer. Table 1-5 presents the region's annual average climate data. The temperature, rainfall, and standard monthly average evapotranspiration (ETo) is provided by the California Irrigation Management Information System (CIMIS) Station Number 78 in Pomona.

Table 1-5: IEUA Service Area Annual Climate

Month	Standard Monthly Average Evapotranspiration (ETo) (inches)	Average Total Rainfall (inches)	Average Temperature (degrees Fahrenheit)	
			Max	Min
January	1.97	3.22	67.46	42.29
February	2.36	3.34	68.03	42.91
March	3.67	2.16	70.13	45.21
April	4.68	1.10	73.20	47.24

1.11 Potential Effects of Climate Change

1.11.1 Overview

The topic of growing interest and research for water planners and managers is climate change and the potential impacts it could have on California's future water supplies. DWR's California Water Plan considers how climate change may affect water availability, water use, water quality, and the ecosystem. The California Water Plan Update 2018 builds upon previous updates and provides recommended actions, funding scenarios, and an investment strategy to meet the challenges and goals laid out in the prior 2013 Plan.

Chapter 3 of the California Water Plan, "Actions for Sustainability", and Volume 1, Chapter 5 of the California Water Plan, "Managing an Uncertain Future," evaluated three different scenarios of future water demand based on alternative but plausible assumptions on population growth, land use changes, water conservation and future climate change (DWR 2019). Future updates will test different response packages, or combinations of resource management strategies, for each future scenario. These response packages help decision-makers, water managers, and planners develop integrated water management plans that provide for resource sustainability and investments in actions with more sustainable outcomes. The 2018 Update provides recommended actions in order to support each of the identified goals of the plan. The goals are 1) Improve Integrated Watershed Management, 2) Strengthen Resiliency and Operational Flexibility of Existing and Future Infrastructure, 3) Restore Critical Ecosystem Functions, 4) Empower California's Under-Represented or Vulnerable Communities, 5) Improve Inter-Agency Alignment and Address Persistent Regulatory Challenges, and 6) Support Real-Time Decision-Making, Adaptive Management, and Long-Term Planning (DWR 2019).

California faces the prospect of additional water management challenges due to a variety of issues including population growth, regulatory restrictions, and climate change. Climate change is of particular interest because of the range of possibilities and their potential impacts on essential operations. The most likely scenarios involve increased temperatures, which will reduce the Sierra Nevada snowpack and shift more runoff to winter months, and accelerated sea level rise. The other much-discussed climate change scenario is an increase in precipitation variability, with more extreme drought and flood events posing additional challenges to water managers (DWR 2014). Even without population changes, water demand could increase. Precipitation and temperature influence water demand for outdoor landscapes and irrigated agriculture. Lower spring rainfall increases the need to apply irrigation water. Further, warmer temperatures increase crop evapotranspiration, which increases water demand. Water-related resources that are considered important and potentially sensitive to future climate change include water demands, water supplies, water quality, sea level rise, flooding, and ecosystem and habitat.

1.11.2 IEUA Climate Change Vulnerabilities

Climate analysis conducted for the 2015 IRP suggests that temperatures within the IEUA service area will rise over the coming decades and that precipitation will continue to be highly variable, with no consensus on a trend towards wetter or drier conditions. It is therefore important to identify water management options that will ensure future demand can be met under a variety of different hydrologic circumstances. Despite uncertainty over the specific effect of climate change on IEUA's water supply, the various projections showed an overall tendency of future decreases in supply sources. The largest potential impact on supply is the vulnerability of imported water from the State Water Project (SWP), indicating a need to improve regional sustainability and decrease dependency on the SWP supply. The 2015 IRP analysis identified recycled water supplies as a critical asset in bolstering a flexible management portfolio since these supplies are generated locally and not impacted by climate. In conjunction with maximizing recycled water supplies, the 2015 IRP also found that the implementation of additional water use efficiency programs would bolster the resiliency of IEUA's water portfolio against climate impacts.

The 2020 Regional DCP also assessed climate change vulnerabilities within the regional's water supply sources. The DCP found that while precipitation variability is expected to align with historical trends, the wet years will likely be wetter and the dry years drier, exacerbating an already highly variable water supply reliability factor (DCP 2020). It is anticipated that the groundwater supply will be adversely impacted by increased temperatures and drought.

Groundwater elevation and water quality are both dependent upon rainfall and supplemental sources of recharge. Droughts similar to the 2011 to 2017 drought could significantly decrease natural groundwater recharge and an increased intensity of storm events could lead to an inability to capture and recharge stormwater (DCP 2020). Stormwater is a high-quality water source that can improve the quality of groundwater supplies once it has infiltrated and blended with the aquifer; a reduction in stormwater recharge could result in a degradation of groundwater quality. In addition, reduced rainfall and increased groundwater withdrawal may lead to more salinity buildup and increased concentrations of salt, nitrate, and other constituents, requiring the need for additional water supply for blending or investment in advanced treatment technologies (DCP 2020). Applications for recycled water in the basin become constrained if the salinity in the basin rises beyond the Regional Water Quality Control Board's (RWQCB's) specified limits.

The largest potential climate change impact on supply is the effect of shifting snowmelt and resulting runoff patterns on the SWP. The SWP's infrastructure was designed to capture snowmelt from the Sierra Nevada snowpack, and when snow melts during the spring and summer months, a combination of reservoirs and conveyance facilities provide a steady water supply throughout the year. The reservoirs were sized based on historical precipitation patterns, so with more precipitation falling as rain instead of snow in the winter months, more water will be required to be released from reservoirs and will not be available during the higher summer demand periods (DCP 2020). The reliability of imported SWP is expected to decrease as the changes in precipitation caused by climate change continue. This decrease in reliability indicates a need to improve regional sustainability and decrease dependency on the SWP supply. The 2015 IRP analysis identified recycled water supplies and WUE as a critical asset in bolstering a flexible management portfolio since these supplies are generated locally and not impacted by climate. In addition, MWD is considering investments in Delta conveyance to minimize potential SWP reductions and has developed a conceptual 150 million gallons per day (MGD) Regional Recycled Water program to further reduce climate change impacts on the SWP.

Local surface water is also an important resource for retail agencies within the IEUA service area. These supplies are dependent on precipitation and temperature, which are influenced by climate change. Extreme precipitation events can result in short periods with high volumes of runoff that will be difficult to capture, while extended droughts or dry years will result in long periods without these supplies. Higher temperatures will also cause more evaporation and transpiration, reducing the volume of water bodies such as lakes, as well as the amount of soil moisture. Reduced soil moisture means that soil may absorb and hold more water when rain occurs, which would reduce the amount of water flowing into creeks and streams.

The climate change effects and their potential to impact supply and demand are considered throughout this document.

1.12 Implementation of the Plan

This subsection provides a cooperative framework within which the Plan will be implemented including agency coordination, public outreach, and resources maximization.

1.12.1 Preparation of the Plan

IEUA's water supply planning relates to the policies, rules, and regulations of its regional and local water providers. IEUA's service area is dependent on imported water from MWD, its regional wholesaler. As such, this 2020 UWMP was developed from a wholesale perspective. While the Wholesale UWMP provides water demand, water supply, and supply reliability assessment for the service area, all requirements of the CWC for each of IEUA's retail agencies will be met through each retail agency's individual 2020 UWMP. This Plan was prepared at a wholesale level, in coordination with retail water agencies within IEUA's service area for consistency. Table 1-6 summaries the varying levels of contribution. Furthermore, IEUA regularly coordinates with retail and regional water agencies for the planning of this UWMP and other documents to support the long-term water planning and management for the region. A detailed description of regional water agency coordination is included in Section 1.13.

Water Facilities Authority	Yes	No	No	Yes	Yes	Yes	Yes

Notes:

(a) IEUA sent notice of plan in preparation in November of 2020 and notice of intent to adopt in April 2021 to all retail agencies, except for WVWD; IEUA sent notice of preparation and notice of intent to adopt with WVWD in May 2021. Both notices are included in Appendix E.
(b) IEUA posted the draft 2020 UWMP to its website on 11 May 2021 and the adopted final 2020 UWMP to its website by July 1, 2021.

1.12.2 Plan Adoption and Amendment Process

IEUA began preparation of this Plan in October 2020. The final version of the Plan was adopted by IEUA Board on June 16, 2021 and submitted to DWR within 30 days of Board approval. The Board Resolution stating the adoption of the 2020 UWMP (Resolution No. 2021-6-10) is included in Appendix D.

Notification of IEUA's intent to amend the UWMP was posted on IEUA's website and provided to the relevant agencies at least 60 days prior to the public hearing. Table 1-7 lists the relevant water suppliers and agencies that IEUA sent a Letter of Notification on November 24 and 30, 2020 that it was in the process of preparing an updated UWMP. A copy of the Letter of Notification is included in Appendix E. A public hearing was held and the final amended UWMP was adopted by the IEUA Board on June 16, 2021 and submitted to DWR within 30 days of Board approval. The amended final UWMP was also submitted to the California State Library, City and County.

This plan includes all information necessary to meet the requirements of the Water Conservation Act of 2009 (Wat. Code, §§ 10608.12-10608.64) and the Urban Water Management Planning Act (Wat. Code, §§ 10610-10656).

Table 1-7: DWR Wholesale: Water Supplier Information Exchange (DWR Table 2-4)

Select One	Supplier
X	Supplier has informed more than 10 other water suppliers of water supplies available in accordance with Water Code Section 10631. Completion of the table below is optional. If not completed, include a list of the water suppliers that were informed.
	Supplier has informed 10 or fewer other water suppliers of water supplies available in accordance with Water Code Section 10631.

Water Supplier or Agency Name
Chino Basin Water Master
Chino Basin Desalter Authority
City of Chino
City of Chino Hills
Cucamonga Valley Water District
Fontana Water Company
Local Agency Formation Commission for San Bernardino County
City of Montclair
Monte Vista Water District
Metropolitan Water District
City of Ontario
City of Rancho Cucamonga
Santa Ana Regional Water Quality Control Board
San Antonio Water Company
Santa Ana Watershed Project Authority
San Bernardino County Planning Department
Three Valleys Municipal Water District
City of Upland
Water Facilities Authority
West Valley Water District

1.12.3 Public Outreach

IEUA encouraged community and public interest involvement in the plan update through a public hearing and inspection of the draft document on June 16, 2021. Public hearing notifications were published in local newspapers. A copy of the published Notice of Public Hearing is included in Appendix E. The hearing provided an opportunity for all residents and employees in the service area to learn and ask questions about their water supply in addition to IEUA's plans for providing a reliable, safe, high-quality water supply. Copies of the draft plan were made available for public inspection at the IEUA headquarters and website.

Table 1-8 presents a timeline for external coordination and outreach during the development of the Plan. A copy of the public outreach materials is provided in Appendix E.

Table 1-8: External Coordination and Outreach

Date	Milestone	External Coordination and Outreach
November 24 and 30, 2020	Notification of Preparation	Encouraged public involvement
April 5, 2021	Notice of Intent to Adopt	Notified the public of the intent to adopt the UWMP and WSCP
May 11, 2021	Draft UWMP and WSCP	Draft UWMP and WSCP released to solicit input
June 16, 2021	Public Hearing	Review contents of Draft UWMP and WSCP and take comments
June 16, 2021	Board Adoption	UWMP and WSCP considered for approval by the Board
By July 1, 2021	Made UWMP and WSCP Available to the Public	Posted on IEUA's website for public access (no later than 30 days after filing with DWR)
By July 13, 2021	Submittal to Library and City/County	Submit the UWMP and WSCP to the California State Library and city or county within service area (no later than 30 days after adoption)

1.12.4 Resource Maximization

Several documents have been developed to enable IEUA and the region to maximize the use of available water resources, including IEUA's 2015 UWMP, the plans described in Section 1.3.1, DWR's 2019 State Water Project Delivery Capability Report (DWR 2019), IEUA's draft 2020 Water Use Efficiency Business Plan, IEUA's Water Shortage Contingency Plan, and communication with IEUA staff. A complete reference list is provided in Section 11 of this Plan.

1.13 Regional Water Agency Coordination

There are many agencies involved in water management within the service area. IEUA is working in cooperation with each of these agencies to achieve water supply reliability, water quality, and watershed management goals for the Santa Ana River Watershed and the Inland Empire. This section provides a description of these agencies.

1.13.1 Metropolitan Water District of Southern California

IEUA is a member agency of MWD, which is a public agency that provides supplemental imported water from the northern California SWP and the Colorado River Aqueduct (CRA) to 26 member agencies located in the Los Angeles, Orange, Riverside, San Bernardino, San Diego, and Ventura Counties. Nearly 90%of the population within these counties, approximately 19 million people, resides within MWD's 5,200-square mile service area.

As a water wholesaler, MWD has no retail customers. It distributes treated and untreated imported water from the CRA and SWP to its member agencies. MWD provides an average of 50% of the municipal, industrial, and agricultural water used within its service area. The remaining 50% comes from local groundwater, local surface water, recycling, and from the City of Los Angeles' Owen's Valley Aqueduct in the eastern Sierra Nevada. MWD prepares its own UWMP. MWD currently provides financial support for local water projects and water conservation projects implemented by its member agencies that increase the reliability of water supplies to the region.

MWD sponsors the Local Resources Program (LRP), established in June 1998, to encourage member agencies to develop and use recycled water and recover groundwater to reduce dependence on imported water supplies. IEUA currently receives financial contributions from MWD from the following programs:

- Conservation Credits Program – MWD pays the lesser of one-half the program cost or the equivalent of $195 per AF of water saved through conservation. A variation of this policy provides funding for programs that document water savings.

MWD also provides financial and technical assistance to its member agencies for implementing the water conservation measures, such as Best Management Practices (BMP), that were initiated by the California Urban Water Conservation Council (CUWCC) Best Management Practices Memorandum of Understanding. CUWCC is now known as the California Water Efficiency Partnership. IEUA currently receives financial contribution from MWD for the following conservation programs:

- Residential and Commercial SoCal Water Smart Program - MWD sponsors a region-wide program that offers single family residents' rebates for high efficiency toilets (HET) and washers, weather-based irrigation controllers, rotating nozzles, and synthetic turf. MWD also provides rebates for plumbing fixture upgrades, landscaping devices, turf replacement, and some industry specific technologies for commercial, industrial, and institutional (CII) customers.

- Residential Landscape Retrofit Program - MWD sponsors outdoor irrigation evaluations and retrofits of high efficiency landscape devices for residential water customers with lot sizes of ¼ acre or larger.

- Residential Pressure Regulation Program – MWD funding supports installation of pressure regulating valves (PRVs) at meters, homes, or at the point-of-connection for irrigation systems to automatically reduce high incoming water pressure from water mains and provide a lower, more functional pressure distribution. PRVs ensure that end-use plumbing fixtures operate at the intended flow rate and reduce the incidence of excessively leaky pipes and fixtures.

- Residential Education, Survey, and Controller Upgrade Program – Focused on the higher water use demographic within the small residential landscape sector, this program promotes an improved understanding of landscape irrigation control technologies while ensuring more efficient scheduling and operation of automated irrigation systems through required training class attendance, landscape evaluations, and smart controller technology upgrades.

- FreeSprinklerNozzles.com Program - This program, which ended in 2019, enabled residential and commercial customers within IEUA's service area to obtain a voucher for free high efficiency irrigation spray nozzles through a web-based portal.

1.13.2 Santa Ana Watershed Project Authority

The Santa Ana River Watershed faces enormous challenges as it strives to adapt to changing conditions, many of which are at an unprecedented scale in its modern history. The Santa Ana Watershed Project Authority (SAWPA) acts as the Regional Water Management Group and its mission is to facilitate communication, identify emerging opportunities, develop regional plans, secure funding, implement programs, build projects, and operate and maintain facilities.

IEUA is a member of SAWPA, which was formed in 1972. SAWPA is a Joint Powers Authority (JPA) that coordinates regional planning within the Santa Ana River Watershed to address water quality and supply improvements. SAWPA is comprised of the five major water supply and wastewater management agencies within the Santa Ana Watershed including: IEUA, Eastern Municipal Water District, Orange County Water District, San Bernardino Valley Municipal Water District, and Western Municipal Water District.

Since the early 1970s, SAWPA has played a key role in developing and updating the Regional Basin Plan for the California Regional Water Quality Control Board. SAWPA conducts water-related investigations and planning studies, and builds facilities needed for regional water supply and water quality remediation.

The "One Water One Watershed" (OWOW) is the Santa Ana River Watershed's integrated regional water management plan. This plan reflects a collaborative planning process that addresses all aspects of water resources throughout the region and watershed. OWOW integrates different disciplines such as: water supply, water quality, recycled water, stormwater management, water use efficiency, land use, energy use, climate change, and habitat. It includes planning of future water demands and supplies over a 20-year time horizon within the watershed as a hydrologic and interconnected system. The plan represents collaboration across jurisdictions, and political boundaries involving multiple agencies, stakeholders, individuals, and groups; and attempts to address the issues and differing perspectives of all the entities involved through mutually beneficial solutions. The plan's comprehensive view of the watershed and water issues is one in which all types of water (imported, local surface and groundwater, stormwater, and wastewater effluent) are viewed as components of a single water system, inextricably linked to land use and land cover.

1.13.3 Chino Basin Watermaster

IEUA is a member of the CBWM Board of Directors. CBWM was established in 1978 by a judgment entered by the Superior Court of California. The judgment requires that the CBWM develop a management plan for the Chino Groundwater Basin that meets water quality and quantity objectives for the region.

In 1998, CBWM developed an integrated set of water management goals and actions for the Chino Basin known as the Optimum Basin Management Program (OBMP) that describes nine program elements to meet the water quality and local production objectives in the Chino Groundwater Basin. The OBMP encourages the increased use of local supplies to help “drought proof” the Chino Basin.

In July 2000, CBWM adopted the “Peace Agreement” that ended over 15 years of litigation within the Chino Basin. The Peace Agreement outlined the schedule and actions for implementing the OBMP. In December 2007, CBWM adopted the “Peace II Agreement” that redefined the future programs and actions required to implement the OBMP, based on the 9 years of experience and accomplishments in implementing the OBMP. Between 2009 and 2010, CBWM updated the Groundwater Recharge Master Plan in response to changes in demand, recharge capacity, safe yield, and other factors.

CBWM recently concluded the 2020 OBMP Update through a year-and-a-half long process that gathered input from all stakeholders. The management plan contained in the 2020 OBMP outlines a series of activities proposed by the stakeholders to achieve the goals of the 2020 OBMP which are: 1) Enhance Basin Water Supplies, 2) Protect and Enhance Water Quality, 3) Enhance Management of the Basin, and 4) Equitably Finance the OBMP. Implementation of the management plan will require an updated Implementation Plan, and amendments to the Peace Agreement. This is especially true of the storage management component of the OBMP, which needs to be updated and adopted by the Court before June 30, 2021.

As the environmental review of the 2020 OBMP Update has not yet been completed, CBWM developed a Local Storage Limitation Solution addendum, which allows the continued temporary utilization of managed storage under the 2000 OBMP. The efforts to fully complete the 2020 OBMP Update environmental review and Implementation Plan should advance in a timely manner to ensure the adequate protection of the regional groundwater supply. The Chino Ground Basin is a very important resource that the region relies on for supporting its vibrant economy and growing population. The 2020 OBMP and future Implementation Plan, including the revised Storage Management Plan is essential to reliably maintain this significant groundwater resource.

1.13.4 Chino Basin Water Conservation District

The Chino Basin Water Conservation District (CBWCD) was established in 1949 to protect and replenish the Chino Groundwater Basin with rainfall and stormwater runoff from the San Gabriel Mountains. CBWCD uses an extensive system of percolation ponds and spreading grounds to augment the natural capacity of the region to capture runoff for recharge. CBWCD also promotes water conservation through public education programs. IEUA works closely with the CBWCD. IEUA, CBWM, the San Bernardino County Flood Control District, and CBWCD jointly sponsor the Chino Basin Recycled Water Groundwater Recharge Program that is an integral part of basin water management.

1.13.5 Santa Ana Regional Water Quality Control Board

The Santa Ana Regional Water Quality Control Board (SARWQCB) is responsible for the development and enforcement of water quality objectives to meet the requirements of the Federal Clean Water Act, California Porter-Cologne Act, and the National Pollutant Discharge Elimination System (NPDES).

In 1975, the SARWQCB completed the Water Quality Control Plan for the upper portion of the Santa Ana Watershed. The plan outlined specific water quality management actions to address water quality and salt build up, in the form of total dissolved solids (TDS) within the Chino Groundwater Basin. These included the construction of a large well field and desalters in the lower part of the Chino Basin to extract and treat poor quality water, and construction of a pipeline to export brine from the upper Basin to the Orange County Sanitation District (OCSD) Plant 1. The Water Quality Control Plan was updated in 1995, 2008, 2011, 2016, and 2019.

The Inland Empire Brine Line (IEBL), previously known as the Santa Ana River Interceptor, was built and has been in operation since 1975. The 2020 OBMP Update by CBWM has been developed to meet the requirements of the 1975 Plan.

1.13.6 Chino Basin Desalter Authority

The CDA is a JPA consisting of the cities of Chino, Chino Hills, Norco and Ontario, the Jurupa Community Services District, the Santa Ana River Water Company, Western Municipal Water District, and IEUA. The CDA treats brackish groundwater from the lower Chino Basin with the Chino I and II Desalter facilities along with distribution of drinking water to retail agencies. IEUA operates and maintains the Chino I Desalter while Jurupa Community Services District operates and maintains the Chino II Desalter. These desalter facilities consist of groundwater wells and associated raw water pipelines, treatment facilities, pumps, and water distribution pipelines. Treatment processes include ion exchange (IX) and reverse osmosis (RO). Three of the nine retail agencies currently purchase desalted water as part of their water supply.

1.13.7 San Bernardino County Flood Control District

The SBCFCD is partnering with IEUA, CBWM, and CBWCD in implementation of the Chino Basin Groundwater Recharge Master Plan. The implementation is known as Chino Basin Facilities Improvement Program (CBFIP). The CBFIP includes modifications to several SBCFCD basins and flood control channels including the installation of five rubber dams and three drop inlet diversion structures to divert imported, storm and recycled water to 16 groundwater recharge sites.

1.14 Fundamental Findings of the Urban Water Management Plan

It is the stated goal of the IEUA to deliver a reliable and high-quality water supply to its service area, even during dry periods. The analysis in this Plan documents that IEUA and its service area will have sufficient supply to meet water use demands out to 2045 during all considered dry period scenarios. The region has also successfully achieved its goal of reducing water use by 20% by 2020 as part of SBX7-7. The Plan documents IEUA's commitment to conservation and support of water use efficiency programs for its retail agencies to continue water demand reduction. IEUA has identified recycled water use as an important source of supply currently and in the future and continues to explore other potential supply opportunities which are described throughout the document. Finally, the Plan considers potential impacts to each of its supply sources due to climate change, regulations, and water quality changes and addresses potential future actions needed to increase the resiliency of the region.

Section 2: Water Demands

This section describes historical, current, and projected water usage and demands within IEUA's service area. Regional water demands represent the total demand of all agencies within IEUA's service area over the planning horizon. These demands are broken down by retail agency in the following subsections.

Since the 1990s, approximately 90% of the region's water demands have come from urban municipal and industrial (M&I) users with the remaining 10% coming from agricultural users. Overall urban water demand since 1995 has increased by approximately 20%, despite a regional growth of 30% (approximately 200,000 more residents). This is indicative of new water use behaviors, such as efficient irrigation and the use of more efficient indoor fixtures, which prolong the availability of current regional water supplies into the future. Water use efficiency measures implemented by IEUA and its retail agencies are discussed in detail in Section 8.

The 2015 UWMP projected 2020 total urban demand to be approximately 210,500 AFY. However, actual demands have decreased over the past 5 years from 200,000 AF in FY 14/15 to 192,202 AF in FY 19/20. Over the past 5 years, the average water usage has been even lower, approximately 187,500 AFY (ranging from 168,800 AF in FY 15/16 to 203,400 AF in FY 17/18). This decrease is in part due to slow population growth (approximately 0.9% growth per year), changes in plumbing codes, implementation of water use efficiency programs, and the increased education and of consumers about California drought conditions and their subsequent conservation measures.

While IEUA anticipates a slight increase in water usage in the future due to the growing population in the region and the projected temperature increases, long-term demands are not expected to exceed the peak 10-year demand of 227,586 AF reached during the FY 13/14 drought. The 2015 Integrated Water Resources Plan demand modeling found that new developments in the region are more efficient due to changes in the plumbing code, higher density developments with less landscaping, and compliance with landscape ordinance requirements set forth in AB 1881. A continued focus on water use efficiency and per capita reductions, as required in SBX7-7, AB 1668, and SB 606, is anticipated to continue reducing overall water demands.

The impact of state-wide mandates has also affected demand in the region. The Water Conservation Act of 2009 (SBX7-7) provides the regulatory framework to support the statewide reduction in urban per capita water use described in the 20x2020 Water Conservation Plan (DWR 2010). As detailed in Section 3, the IEUA region has reduced its gallons per capita per day water usage by more than 20% compared to the baseline value calculated in 2010.

These findings suggest that future developments will require less water than in the past, reducing the previous projected regional need for additional water supplies. This shift has significant implications for future wastewater and recycled water planning. Regional treatment plants may not need to be expanded for hydraulic capacity as quickly as previously thought; however, treatment plants will have to be expanded to treat increased wastewater strength due to greater solids concentration, and future available recycled water supplies may be lower than previously expected.

Several factors can affect demands and associated projections, including:

- Land use revisions
- New regulations
- Consumer choice
- Economic conditions
- Transportation needs
- Environmental factors
- Conservation programs
- Building and plumbing codes.

These factors affect the amount of water needed, as well as the timing of when it is needed. During an economic recession, there is a major downturn in development and a subsequent slowing of the projected demand for water. The projections in this Plan do not attempt to forecast recessions or droughts. Likewise, no speculation is made about future building and plumbing codes or other regulatory changes.

2.1.1 Demand Projection Methodology

IEUA has been working with its consultant and its contracting agencies on wastewater and recycled water land use-based demand forecasts. The goal of this effort is to develop potential demand projections that disaggregates regional data to the agency level. The project is collecting and compiling data, developing flow factors, unit demands, and agency demands in 5-year increments, and preparing a spreadsheet model and technical memorandum. The effort is estimated to be completed by the submission of IEUA's 2020 UWMP. Draft projections were provided for inclusion in this 2020 UWMP.

In addition, projections on local water supply and demand and retail agency demands on IEUA were gathered from each of IEUA's retail agencies. These projections were prepared by retail agencies for use in their respective 2020 UWMPs. Retail agencies within the service area used various methodologies based on the best available data, land use changes, climate change, and conservation efforts to create their retail demand projections. These agencies also worked with others, such as developers and municipal departments, to refine their projections. Retail agency projections were also informed by the comprehensive IEUA IRP developed in 2014-2016 and the 2020 IRP Regional Water Supply Infrastructure Model (IRP Model). These planning documents were developed in collaboration with IEUA's retail agencies for the purpose of assessing water supply vulnerabilities and evaluating infrastructure and management strategies that will improve near-term and long-term water resources management for the region. The IRP evaluated new growth, development, and water demand patterns within the service area and assessed water needs and supply source vulnerabilities under climate change. The IRP provided aggregated water demand projections based on an econometric demand forecasting model. The IRP Model incorporated existing regional and local supplies, key local and regional infrastructure, interconnections between agencies, and current and projected annual potable water demands to simulate requirements for imported water or other sources to blend with and utilize wells with impaired groundwater quality. The IRP Model evaluated multiple scenarios to identify areas with unmet water demands and areas with water surpluses.

IEUA coordinated with its retail agencies to collect retail supply and demand data that was gathered into regional totals. Additional details on the demand projection methodology completed by each retail agency can be found in their respective 2020 UWMPs. Coordination with land use agencies to develop water projections for both IEUA and its retail agencies are detailed in the following section.

2.1.2 Coordination with Land Use Agency to Develop Water Projections

It is important to have city land use planners identify anticipated timing of development as they are the most knowledgeable of development activities, growth patterns, and trends within their city. The 2015 IRP and 2015 Land Use-Based Demand Model (LUBDM) included significant considerations of land use and coordination with regional agencies to develop accurate water projections that were again referenced for the development of the 2020 UWMP water projections. Land use data used for the 2015 LUBDM were sourced from the General Plans of the cities in the region, the Metropolitan Water District's 2010 water demand model, and regional growth plans, such as SCAG's 2012-2035 RTP/SCS. The 2015 LUBDM and IRP were created to provide consistently developed agency demand projections through 2040. In addition to the sources mentioned, this model developed land use designations for the service area using existing land use geospatial information system databases, Google Earth, windshield surveys, and meetings with community development departments. The 2015 IRP project team met with planning or community development departments for each City within IEUA's service area: the cities of Chino, Chino Hills, Fontana, Montclair, Ontario, Rancho Cucamonga, and Rialto. These meetings focused on confirmation of general plan land use for vacant land that is developable and confirmation of boundaries and existing land uses. The extensive effort to improve the classification accuracy of over 70% of the existing land use resulted in a detailed database of existing land use.

Additional details on land use agency coordination conducted by retail agencies for the 2020 planning effort can be found in each individual retail agencies' 2020 UWMP.

2.1.3 Current and Projected Land Use

As discussed in Section 1.7, when IEUA was formed, land use within the service area was primarily field crops, citrus, and vineyards. Since then, urban areas have expanded significantly and replaced many agricultural uses in the northern and central portions of the Chino Basin. The conversion of agricultural land to urban developments is anticipated to continue for land use within the Chino Basin based on the region's general plans. Residential land use is expected to grow significantly over the next two decades, while vacant and agricultural land is expected to decrease by over 85%. Industrial land use is projected to increase as well, although not as much as residential land use.

2.2 Non-Potable Versus Potable Water Use

Water use in IEUA's service area includes both potable and non-potable water. While IEUA does have a non-reclaimable water system, which includes industrial wastewater that cannot be feasibly reclaimed and exported for disposal, the only non-potable water reported in this UWMP is recycled water. Within Section 3, gross water use indicates water use that does not include recycled water. IEUA water demands have been split into imported water and recycled water for clarity. It is important to distinguish between potable and non-potable demands because recycled water supplies have limited permitted uses. Where possible, retail agencies' demands have been split into potable and non-potable demand. Additional details on recycled water uses and projections are included in Section 5.

It should be noted that water use may shift from potable to non-potable water use or vice versa. As IEUA works to maximize and optimize recycled water use and decrease reliance on imported water, some potable water demands may shift over time to become non-potable water demands. In addition, there is some overlap between recycled water demands and potable water supplies. Recycled water that is used for groundwater recharge will eventually be used as potable local groundwater supply.

2.3 Past, Current, and Projected Water Use by Sector

Retail suppliers must identify water use for at least each of the 10 water use sectors identified in Water Code Section 10631(d), which include:

- Single-family residential
- Multi-family
- Commercial
- Industrial
- Institutional and governmental
- Landscape
- Sales to other agencies
- Saline water intrusion barriers, groundwater recharge, or conjunctive use
- Agricultural
- Distribution system water losses.

Wholesale suppliers are only required to report their direct uses but may choose to report an aggregation of all customer reported water uses by sector. Additional water use sectors may be necessary to account for the entirety of an agencies water uses. "Other" water use sectors may include exchanges, surface water augmentation, transfers, wetlands or wildlife habitat, or other, as appropriate.

IEUA has worked with its retail agencies to provide water use data for IEUA as a wholesaler and by retail agency for the purposes of transparency and comprehensive future planning. IEUA's retail agencies have also prepared 2020 UWMPs that include details on their individual water use by sector.

2.3.1 IEUA Water Use

As a wholesaler, IEUA supplies untreated imported water that is purchased from MWD and supplied to its retail agencies. In FY 2019-2020, 66,438 AF of untreated imported water was supplied to its retail agencies, as shown in Table 2-1.

Table 2-1: Demands for Potable and Non-Potable Water – Actual (DWR Table 4-1)

2020 Actual			
Use Type	**Additional Description**	**Level of Treatment When Delivered**	**Volume (acre-feet)**
Sales to other agencies	MWD Imported Water	Raw Water	66,438
		TOTAL	**66,438**

Note: Volume values from IEUA Annual Water Use Database.

2.3.2 Water Use by Retail Agency

The total water use of IEUA's eight retail agencies for FY 19-20 is shown in Table 2-2. Total water use includes recycled water for direct use but not recycled water for groundwater recharge. The total water use for FY 19-20 was 192,100 AF. The water use of the retail agencies is met by local surface water, stormwater, Chino Basin groundwater, non-Chino groundwater, and the Chino Basin Desalters, in addition to the imported water supplies by MWD through IEUA and the recycled water for direct use shown in Table 2-1.

Table 2-2: Water Demand by Retail Agency – Actual

Retail Agency	Volume in Acre-Feet (2020 Actual)
City of Chino	19,303
City of Chino Hills	14,493
Cucamonga Valley Water District	47,059
Fontana Water Company[a]	37,804
Monte Vista Water District	9,035
City of Ontario	39,666
San Antonio Water Company	6,219
City of Upland	18,520
TOTAL	**192,100**

Notes: Volume values from FY 19/20 Annual Water Use Report; includes recycled water for direct use; does not include recycled water for groundwater recharge. Interagency transfers within the region are not included.
(a) Includes demands within IEUA service area only.

2.4 Distribution System Water Losses

In addition to the traditional demand sources, there is another component that impacts water resources – "water losses." Water losses are typically defined as the difference between water production and water sales. These water losses can come from authorized, but unmetered sources, such as firefighting and main flushing, or unauthorized sources such as leakage, illegal connections, and inaccurate flow meters. Retail water agencies are required to calculate their current and projected water losses using the American Water Works Association Method (Title 23 California Code of Regulations Section 638.1 et seq).

Wholesale suppliers are not required to perform water loss audits or report any distribution system losses, although it is recommended that they estimate losses for reliability planning and projecting water needs.

IEUA does not own or operate any potable water infrastructure, and therefore, does not have any distribution losses to report.

2.5 Projected Water Use

Estimating future water demand is a function of several factors. Water usage is influenced by geographic location, topography, land use, demographics, and water system characteristics (i.e., system pressures, water quality, and metering of connections).

2.5.1 IEUA Projected Water Use

A key component of the 2020 UWMP is to provide insight into the future water demand outlook of the region in addition to IEUA's service area. Demand is met through a diverse portfolio of groundwater, purchased imported water from MWD, local surface water, desalinated water, and recycled water (all of which are described in Section 4). IEUA, as the regional wholesaler, is responsible for the purchase of imported water and the provision of recycled water.

Table 2-3 identifies IEUA's projected demand for imported water, which is the maximum volume its retail agencies are contracted to purchase within a given year. Resolution No. 2014-12-1 (also known as the Purchase Order Agreement) establishes the allocations for the purchase of imported water from IEUA by WFA, CVWD, and FWC for a volume less than or equal to 69,572 AFY. Under the IEUA-MWD contract, IEUA is able to purchase up to 93,283 AFY of imported water from MWD at the Tier 1 rate. If the projected imported water demand for a retail agency increases above the values in Resolution No. 2014-12-1, updates to the Resolution may be required. The quantity of imported water available may be less than the contract amount during drought years; water supply reliability is discussed in detail in Section 7. In FY19/20, IEUA's service area purchased 66,438 AF of imported water from MWD, which met 35% of the region's total water use. IEUA and its retail agencies aim to decrease their reliance on imported water by pursuing a variety of water use efficiency and conservation strategies, along with maximizing the recycled water use within the region. While efforts are being made to reduce IEUA's imported water demand to less than its contract amount with the retail agencies in the future, conservative planning assumptions are being made by retail agencies regarding imported water needs in case projects are delayed and/or savings are not realized. This conservative planning approach, and the relatively low imported water use compared to historical use in FY

19/20, accounts for the increase in potable and raw water use between 2020 and 2025 in Table 2-4.

Table 2-4 identifies IEUA's total water demands, which includes the imported water demand projections and the recycled water demand projections. Recycled water demand is projected to increase modestly over the planning horizon, to approximately 9% of total demands by 2045. For additional details on IEUA's recycled water program, refer to Section 5. IEUA currently meets 37% of total water demands within the region; this percentage is expected to decrease to 32% of total demands within the service area by 2045. The IEUA region plans to meet future demand through the diversification of local supply sources, water use efficiency measures, improved groundwater basin management, and the maximization of recycled water use.

Table 2-3: Use for Potable and Raw Water – Projected (DWR Table 4-2)

Use Type	Additional Description	Projected Water Use				
		2025	2030	2035	2040	2045
Sales to other agencies		77,416	79,630	81,974	84,021	84,065
TOTAL		**77,416**	**79,630**	**81,974**	**84,021**	**84,065**

Note: Values from retail agency projections for use of imported water from MWD through IEUA.

Table 2-4: Total Water Use (Potable and Non-Potable) (DWR Table 4-3)

	2020	2025	2030	2035	2040	2045
Potable and Raw Water	66,438	77,416	79,630	81,974	84,021	84,065
Recycled Water Demand	30,496	39,300	41,297	42,162	44,191	44,691
TOTAL WATER DEMAND	**96,934**	**116,716**	**120,927**	**124,136**	**128,212**	**128,756**

Note: 2020 Values from FY 19/20 Recycled Water Annual Report and Annual Water Use Database. Projected potable and raw water volumes is the sum of each retail agency's expected use of imported water from MWD through IEUA. Recycled water direct use projections from retail agencies and groundwater recharge projections from IEUA.

2.5.2 Projected Water Use by Retail Agency

Table 2-5 presents the water demands for the IEUA service area by retail agency for the years 2020 to 2045. These demands include imported water, surface water, groundwater, desalinated water, and recycled water.

Table 2-5: Water Demand by Retail Agency – Projected

Retail Agency	2025	2030	2035	2040	2045
City of Chino	20,843	22,310	23,087	23,963	25,108
City of Chino Hills	17,120	17,334	17,678	17,725	17,769
Cucamonga Valley Water District	53,369	58,092	59,650	60,949	60,949
Fontana Water Company	45,593	46,909	47,665	50,442	51,943
Monte Vista Water District	14,232	14,564	15,175	15,437	15,706
City of Ontario	52,550	58,513	63,406	73,668	73,668
City of Upland	25,328	25,328	25,328	25,328	25,328
TOTAL	**229,035**	**243,050**	**251,989**	**267,512**	**270,471**

Note: Provided by retail agencies in preparation of their respective 2020 UWMPs. SAWCo is not included in the table because transfers from SAWCo are reported within receiving member agency values. Wholesale demands from MVWD to Chino Hills are reflected under Chino Hills' retail demands.

2.5.3 Water Use Projections for Lower Income Households

SB 1087 requires that water use projections of an UWMP include the projected water use for single-family and multi-family residential housing for lower income households as identified in the housing element of any city, county, or city and county in the service area of the supplier. This requirement only applies to retail suppliers; therefore, IEUA is exempt from this requirement. Details on water use projections for lower income households completed by IEUA's retail agencies can be found in each individual retail agency's UWMP.

2.6 Effects of Climate Change on Water Usage

A major factor that affects water usage is weather. Historically, when the weather is hot and dry, water usage increases. The amount of increase varies according to the number of consecutive years of hot, dry weather and the conservation activities imposed. During cool, wet years, historical water usage has decreased, reflecting less water usage for exterior landscaping. Therefore, even without population changes, water demand could increase as a result of climatic conditions. Precipitation and temperature influence water demand for outdoor landscaping and irrigated agriculture. Lower spring rainfall increases the need to apply irrigation water. Further, warmer temperatures increase crop evapotranspiration, which increases water demand.

Climate projections suggest that temperatures within the IEUA service area will rise over the coming decades; there is also expected to be an increase in the frequency, magnitude, and duration of heat waves, causing longer, drier, and more frequent periods of drought. The 2015 IRP found that water demand in its service area may increase by 4.3% for a 3.6^{o} F temperature increase by 2040. In addition, dry years are expected to result in increased water demand; IEUA estimates that 1 dry year would increase demand by up to 5.6% by 2040 while a longer period of dry weather (3+ years) would increase demand by up to 8.9% by 2040.

2.7 Effects of Codes, Standards, and Ordinances

In recent years, water conservation has become an increasingly important factor in water supply planning and management in California. Over the past 10 years there have been a number of regulatory changes related to conservation including new standards for plumbing fixtures, a new statewide landscape ordinance, a state universal retrofit ordinance, new Green Building standards, demand reduction goals and more. In 2018, the California State Legislature enacted Assembly Bill 1668 and Senate Bill 606 to establish a new foundation for long-term improvements in water conservation and drought planning to adapt to climate change and the resulting longer and more intense droughts in California. The California plumbing code has also instituted requirements for new construction that mandate the installation of ultra-low-flow toilets and low-flow showerheads. It is assumed that these changes in water use behavior will continue as the state continues to pass legislation like AB 1668 and SB 606 that create a long-term water conservation framework. A summary of current codes, standards, and regulations impacting regional water demand is included in Table 2-6.

Residential, commercial, and industrial usage can be expected to further decrease as a result of the implementation of more aggressive water conservation practices. In southern California, the greatest opportunity for conservation is in developing greater efficiency and reduction in landscape irrigation. The irrigation demand can typically represent as much as 70% of the water demand for residential customers depending on lot size and amount of irrigated turf and plants. Conservation efforts will increasingly target this component of water demand. IEUA's WUEBP includes "passive" policy initiatives, such as landscape ordinances, and "active savings" that reduce water demand.

"Passive" water saving initiatives that IEUA has employed include residential and commercial high-efficiency toilets, high efficiency clothes washers, and turf replacement. Table 8-6 in Section 8 shows the estimated annual water savings to be achieved over the next 5 years. More details on IEUA's conservation efforts are provided in Section 8.

Table 2-6: Codes, Standards, and Regulations Impacting Water Demand

Regulatory Statute	Requirements	Agency or Regional Implementation	Approach
Assembly Bill 1668 and Senate Bill 606	Compliance with new water use targets, development of Water Shortage Contingency Plans, water loss audits	Implemented locally by water agency	Continuation of water use efficiency programs and policy initiatives. Development of WSCP and 5-year Drought Risk Assessment within the UWMP
20x2020 (SB X7-7)	Reduce per capita water use 20% over baseline by 2020	Implemented by the Regional Alliance	Implementing active water use efficiency programs and policy initiatives within the region
AB1881 – Model Water Efficiency Landscape Ordinance	ETo Allowances: Residential 0.55 Commercial 0.45	Implemented locally by city and/or county	Agencies need to educate customers and developers about ordinance requirements
Assembly Bill 715	Requires any toilet or urinal sold or installed in California cannot have a flush rating exceeding 1.28 and 0.125, respectively	Manufacturers, distributors, retailers, plumbers, and customers must all adhere to new standards	Supply chain removes non-conforming fixtures from marketplace and supplies only efficient and conforming fixtures
Senate Bill 407	Requires existing buildings comply with 1992 standards	Implemented locally by city and county	Difficult to enforce. Could be added to current criteria for change of ownership inspections and reporting

Regulatory Statute	Requirements	Agency or Regional Implementation	Approach
CalGreen	20% reduction of water use. Designated irrigation controllers shall be weather- or soil moisture-based	Implemented locally by city and county	Difficult to enforce. Could be added to current criteria for change of ownership inspections and reporting
Senate Bill 555	Requires water agencies to submit annual water loss reports	Implemented by Agencies	Agencies compile data and submit report to DWR
Assembly Bill 1	City or county cannot fine customers for failure to water	Local agencies to follow requirements of the bill	Agencies need to communicate requirements with cities and counties
Assembly Bill 349	HOAs cannot prohibit installation of artificial turf and allows for turf removal and installation of low water use plants	Local agencies to follow requirements of the bill	Agencies need to work with HOA's and community groups to educate about the bill

Section 3: SB X7-7 Baseline and Targets

3.1 Existing and Target Per Capita Water Use

The Water Conservation Act of 2009 (SBX7-7) is one of four policy bills enacted as part of the November 2009 Comprehensive Water Package (Special Session Policy Bills and Bond Summary). The Water Conservation Act of 2009 provides the regulatory framework to support the statewide reduction in urban per capita water use described in the 20x2020 Water Conservation Plan (DWR 2010). Consistent with SBX7-7, each water supplier must determine and report its existing baseline water consumption and establish water use targets in gallons per capita per day (GPCD) and compare actual water use against the target; reporting began with the 2010 UWMP. The primary calculations required by SBX7-7 are summarized in Table 3-1.

IEUA, as an urban wholesale water supplier, is not required to develop a baseline or set reduction targets to achieve a 20% reduction in GPCD by 2020. However, as the statute does require urban retail water suppliers to comply, IEUA prepared a regional approach establishing a baseline and setting targets based on regional demands in support of its retail agencies. All retail agencies within IEUA's service area have agreed to the formation of a regional alliance and will continue to cooperatively participate in developing WUE programs and meeting water conservation goals.

As a wholesale water supplier, IEUA is required to provide an assessment of its present and proposed WUE measures, programs, and policies that will help its retail water suppliers achieve their water reduction goals. IEUA and its retail agencies have developed core strategies to meet compliance requirements through a collaborative process that focuses on aligning activities with established regional water use efficiency principles and goals.

Table 3-1: SBX7-7 Calculation Requirements

	2010 UWMP	2015 UWMP	2020 UWMP
Base Daily Water Use calculation (average GPCD used in past years)	First calculated and reported in the 2010 plan	May be revised in 2015 Plan; must be revised if 2010 Census data not used in original calculation	NA
Interim Water Use Target (target GPCD in 2015)	First calculated and reported in 2010 Plan	May be revised in 2015 Plan; must be revised if 2010 Census data not used in original calculation	NA
Compliance Water Use Target (target GPCD in 2020)	First calculated and reported in 2010 Plan	May be revised in 2015 Plan; must be revised if 2010 Census data not used in original calculation	NA
Actual 2015 Water Use (in GPCD)	NA	In 2015, Plan must compare actual 2015 GPCD against 2015 target	NA

	2010 UWMP	2015 UWMP	2020 UWMP
Actual 2020 Water Use (in GPCD)	NA	NA	In 2020, Plan must compare actual 2020 GPCD against 2020 target

In the 2020 UWMP, a water supplier must demonstrate compliance with the target established in 2015. Compliance is done through the review of the SBX7-7 Verification Tables submitted with the 2020 Plan (included as Appendix F).

The Base Daily Water Use calculation is based on gross water use by an agency in each year and can be based on a 10-year average ending no earlier than 2004 and no later than 2010, or a 15-year average if 10% of 2008 demand was met by recycled water. Base Daily Water Use must account for all water sent to retail customers, excluding:

- Recycled water
- Water sent to another water agency
- Water that went into storage.

It is at an agency's discretion whether to exclude agricultural water use from the Base Daily Water Use Calculation. If agricultural water use is excluded from the Base Daily Water Use calculation, it must also be excluded from the calculation of actual water use in later urban water management plans. IEUA did not adjust for agriculture exclusions in the SBX7-7 calculations.

Finally, the selected Compliance Water Use Target must be compared against what DWR calls the "Maximum Allowable GPCD." The Maximum Allowable GPCD is based on 95% of a 5-year average base gross water use ending no earlier than 2007 and no later than 2010. The Maximum Allowable GPCD is used to determine whether a supplier's 2015 and 2020 per capita water use targets meet the minimum water use reduction requirements of SBX7-7. If an agency's Compliance Water Use Target is higher than the Maximum Allowable GPCD, the agency must instead use the Maximum Allowable GPCD as its target.

3.1.1 Historical Demand, Selected Baseline, and 20x2020 Targets

In the 2010 UWMP, the baseline and water use targets for the IEUA regional alliance were calculated using an aggregate of individual agency water use and population information to calculate one baseline GPCD for the whole IEUA region. To do this, IEUA along with its retail agencies analyzed historical retail demand data from 1995 to 2010 and selected a 10-year baseline period (1999 to 2008). The aggregate of individual agency water use and population information for the same period were used to calculate the regional alliance's baseline GPCD and water use targets for 2015 and 2020. The targets set in the 20x2020 Water Conservation Plan do not include recycled water use. Thus, recycled water use was subtracted from historical recycled water production to get retail demands for non-recycled supplies. The 2015 interim target and the 2020 target was a 10 and 20% reduction from the baseline GPCD, respectively.

The GPCD baselines and targets found using the regional aggregate approach are summarized in Table 3-2.

Table 3-2: 2010 Regional Alliance GPCD Baseline and Targets

Baseline Period	Baseline	2015 Target (10% Reduction)	2015 Actual	2020 Target (20% Reduction)
1999-2008	251	226	160	201

Note: From 2010 IEUA UWMP.

In 2015, an alternative approach to calculating the regional water use targets was carried out to compare findings. For this method, each water supplier in the regional alliance first calculated its individual target in its retail UWMP as if it were complying individually. Then, the individual targets were weighted by each supplier's population and averaged over all members in the alliance to determine the regional water use target. The GPCD baseline and target found for the 10-year baseline period using the population weighted average approach is summarized in Table 3-3. The 2020 Target in Table 3-3 is used to determine 2020 compliance.

In the 2015 UWMP, IEUA demonstrated compliance with its regional alliance 2015 interim target, indicating that the alliance was on track to meet the 2020 water use target.

Table 3-3: 2015 Regional Alliance GPCD Baseline and Targets (DWR Table 5-1R)

Baseline Period	Year Span	Average Baseline[(a)]	2020 Target[(a)] (20% Reduction)
10 year	1995 – 1999 to 2004 - 2008	245	193

Notes:
The 10-year baseline period was selected for the 2020 Compliance Water Use Target.
The 5-year period average baseline value in included in DWR Table 5-1 in Appendix C.
(a) All values reported as gallons per capita per day (GPCD).

3.1.2 2020 Compliance

In this 2020 UWMP, the regional alliance must demonstrate compliance with its 2020 water use target. IEUA chose to use the same approach that was completed in 2015. Each of IEUA's retail agencies first calculated its individual target in its retail UWMP, then the individual targets were weighted by each supplier's population over the total population in the IEUA region to determine the 2020 water use in GPCD.

The 2020 population for the total IEUA region, the sum of the populations of each of its retail agencies, is 905,816. This population includes IEUA's total service area, as well as areas outside the service area that are part of its retail agencies, as is the case for Fontana Water Company. This population is used for the calculation of the regional alliance's 2020 GPCD. The retail agencies used different sources for calculating their service area populations, including

SCAG, the DWR Population Tool, and the California Department of Finance. All retail agencies selected compliance method 1.

Table 3-4 summarizes the baseline, 2015 target, 2015 actual, and 2020 target GPCDs as calculated in the 2015 UWMP and includes the 2020 actual GPCD reported by each retail agency. The resulting weighted IEUA region GCPD for 2020 is included in the table.

The actual 2020 water use in the region is 171 GPCD, approximately 11% lower than the 2020 Target of 193 GPCD, indicating compliance and the success of the collective efforts of IEUA and its retail agencies to reduce water use in the region. These efforts include regional and local actions such as:

1. Water Use Efficiency Active Programs – offering customers a portfolio of programs including cost-effective indoor and outdoor water efficiency measures.
2. WUE Passive Policy Initiatives – including building codes and landscape ordinances.
3. Recycled Water Use – reducing demand for potable water by increasing recycled water supply.

IEUA and its retail agencies did not have any applicable optional adjustments for extraordinary events, economic adjustments, or weather normalization, as shown in DWR Table 5-2 in Appendix C, DWR's SBX7-7 compliance verification table.

Table 3-4: 2020 Regional Alliance GPCD Compliance by Retail Agency

Retail Agency	10-15-yr Baseline (GPCD)	2020 Target (GPCD)	2020 Service Area Population	2020 Actual (GPCD)
Chino	237	189	80,808	169

Note: Data provided by retail agencies. IEUA Regional values calculated using weighted average of population and demand.

Section 4: Water Resources

4.1 Overview

IEUA and its retail agencies have developed a diverse portfolio of water supply sources, including groundwater from the Chino Basin and other basins (Cucamonga, Rialto, Lytle Creek, Colton, and the Six Basins groundwater basins), local surface water from creeks originating in the San Gabriel Mountains, recycled water produced locally, and imported water from the SWP via MWD. This section describes the water resources available to IEUA and its service area for the 25-year period covered by the Plan. Both currently available and planned supplies are discussed. Table 4-1 includes the 2020 actual water supplies available for each of IEUA's retail agencies. Table 4-2 shows the projected water supply by category for each of the retail agencies out to 2045. IEUA's supply for its retail agencies, both actual and projected, are included in Section 4.3, which discusses imported water from MWD.

Table 4-1: Retail Agency Water Supplies – Actual (DWR Table 6-8R)

		2020		
Water Supply	**Additional Detail on Water Supply**	**Actual Volume**	**Water Quality**	**Total Right or Safe Yield *(optional)***
Purchased or Imported Water	MWD/IEUA	66,438	Other Non-Potable Water	
Groundwater (not desalinated)	Chino Basin	51,749	Drinking Water	
Groundwater (not desalinated)	Other Basins	26,436	Drinking Water	
Surface water (not desalinated)		16,652	Drinking Water	
Recycled Water	IEUA	16,278	Recycled Water	
Desalinated Water - Groundwater	Chino Desalter Authority	14,649	Drinking Water	
Total		**192,108**		

Note: Data from IEUA Annual Water Use Report Database. Includes recycled water for direct use; does not include recycled water for groundwater recharge. Excludes interagency transfers within the region.

Note: Data provided to IEUA from retail agencies as part of their 2020 UWMP with adjustments made by IEUA to account for interagency transfers. SAWCo transfers/purchases are reported within receiving member agency values. Data shown above includes a transfer from MVWD to Chino Hills of 8,407 AFY.

4.2 Historical and Current Local Water Supplies

4.2.1 Local Surface Water

Several of the retail agencies within the northern part of IEUA's service area have long standing legal rights to divert and treat water supplies from local surface sources in the Santa Ana River watershed. These sources include San Antonio Canyon, Cucamonga Canyon, Day Creek, Deer Creek, Lytle Creek, and several smaller surface streams (DCP 2020). IEUA does not provide local surface water directly to its retail agencies, although it does participate in the capture and recharge of stormwater caused by surface water runoff. Stormwater is discussed in Section 4.2.3.

Production from surface supplies varies dramatically depending on climate conditions. However, when available, local surface water is an extremely valuable resource as it is essentially "free," with the only cost to retail agencies being the operation of necessary facilities to capture, treat and distribute this water (DCP 2020). This is due in part to the high quality of local surface water. Nevertheless, surface water is treated to state and federal drinking water quality standards before it can be served for public use.

4.2.2 Groundwater

4.2.2.1 Historical Groundwater Pumping

Retail agencies within IEUA's service area use local groundwater as a significant source of the water supply. Most of the groundwater comes from the Chino Basin, which is detailed in the following section. Historical groundwater pumping by retail agency for the last 5 years is presented in Table 4-3. The groundwater pumping volume HAS decreased every year since 2016.

Table 4-3: Groundwater Volume Pumped Over Past 5 Years by Retail Agencies

Groundwater Type	Location or Basin Name	2016	2017	2018	2019	2020
Alluvial Basin	Chino Basin Groundwater	76,302	71,272	63,255	60,417	51,749
Alluvial Basin	Other Groundwater Basins	26,607	28,490	28,819	24,294	26,436
	TOTAL	**102,909**	**99,762**	**92,074**	**84,711**	**78,185**

Note: Groundwater volume pumped by IEUA retail agencies. Years represent fiscal year ending. Data from Annual Water Use Reports and Annual Water Use Report Database.

4.2.2.2 Chino Basin Groundwater

The Chino Basin is one of the largest groundwater basins in southern California, containing approximately 5 million acre-feet (MAF) of water with an unused storage capacity of approximately 1 MAF for a total potential of 6 MAF. Groundwater from the Chino Basin accounts for approximately 45% to 60% of the total water used by IEUA's retail agencies in IEUA's service area over the last 10 years. The Chino groundwater basin is managed by the Chino Basin Watermaster established under the 1978 Judgment. IEUA does not provide groundwater directly to its retail agencies.

Approximately 5% of Chino Basin is located in Los Angeles County, 15% in Riverside County, and 80% in San Bernardino County. Chino Basin is bounded by Cucamonga Basin and the San Gabriel Mountains to the north, the Temescal Basin to the south, Chino Hills and Puente Hills to the southwest, San Jose Hills, Pomona, and Claremont basins on the northwest, and the Rialto/Colton Basins on the east. IEUA's service area overlies approximately 70% of Chino Basin.

San Bernardino County Superior Court created the CBWM in 1978 as a solution to lawsuits over historical water right allocations. CBWM is responsible for managing Chino Basin in accordance with the 2000 Peace Agreement, 2007 Peace II Agreement, and the OBMP. CBWM is governed by three stakeholder groups, called Pools. The three Pools consist of:

- Overlying Agricultural Pool: Representing dairymen, farmers, and the State of California

- Overlying Non-Agricultural Pool: Representing area industries
- Appropriative Pool: Representing local cities, public water districts, and private water companies.

Although groundwater is an important local supply, the water quality in the lower Chino Basin area has been impacted by historical agricultural uses and now has high levels of nitrates and TDS (OBMPU 2020). There are also some areas that exceed standards for perchlorate and volatile organic compounds (VOCs). These groundwater supplies require additional treatment, and/or blending with higher quality imported water before it can be used as a potable supply. CBWM works in partnership with municipalities, IEUA, and the SARWQCB to address these water quality problems and to manage the groundwater basin sustainably. Water quality of the Chino Basin groundwater is discussed in detail in Section 6.

Chino Basin is hydrologically subdivided into five groundwater zones or systems, referred to as management zones. Each management zone has a unique hydrology, and actions within one zone have little or no impact on adjacent zones. Management zones are used to characterize the groundwater level, storage, production, and water quality conditions. Throughout these management zones, there are 19 existing spreading basins that have the capability of recharging stormwater, recycled water, and/or imported water into the Chino Basin (OBMPU 2020). A description of each of the management zones is listed below.

- Management Zone 1: This zone is bounded on the southwest by Chino and Puente Hills, on the northwest by the San Jose fault that separates the Chino Basin from the Pomona and Claremont Heights Basins, on the north by an unnamed non-echelon fault system, and on the east by a line that stretches from the southernmost edge of the Red Hill fault to Prado Dam. Groundwater generally flows south with some localized flows to the west in response to groundwater production.
- Management Zone 2: This zone is bounded on the west by Management Zone 1, on the north by the Red Hill fault, on the northeast by a segment of the Rialto-Colton fault, and on the east by a segment of Barrier J. Groundwater generally flows in a southwesterly direction in the northern half of the zone and then due south in the southern half of the zone.
- Management Zone 3: This zone is bounded on the west by Management Zone 2, on the northeast by the Rialto Colton fault, and on the southeast by the Bloomington divide. Groundwater generally flows in a southwesterly direction.
- Management Zone 4: This zone is bounded on the west by Management Zone 3, on the north by the Jurupa Hills, on the southeast by the Pedley Hills, and on the south by Management Zone 5. Groundwater flows west.
- Management Zone 5: This zone is bounded on the north and west by Management Zones 3 and 4, on the east by the Riverside Narrows, and on the south by the La Sierra area and Temescal Basin.

4.2.2.2.1 Sustainable Groundwater Management Act

The Sustainable Groundwater Management Act (SGMA), passed in 2014 and amended in 2015, creates a framework for sustainable, local groundwater management in California. SGMA directed DWR to identify priority groundwater basins for the purpose of implementing SGMA. SGMA requirements to create sustainable groundwater management agencies and sustainable groundwater management plans no later than 2022 applies only to high and medium priority basins. SGMA exempts adjudicated groundwater basins – those that already operate under a court-ordered water management plan – from the requirements of designating a Groundwater Sustainability Agency and developing a Groundwater Sustainability Plan. The Chino Basin is an adjudicated basin and is included in SGMA's list of exempt basins. The Chino Basin priority is "very low" as established by the DWR in the 2019 Basin Prioritization Report.

4.2.2.2.2 Chino Basin Management and Safe Yield

The Chino Basin is managed according to the 1978 Judgement described in Section 1. In 1998, the Chino Basin Watermaster developed an integrated set of water management goals and actions for the basin known as the Optimum Basin Management Program (OBMP). The goals of the OBMP are to enhance basin water supplies, protect and enhance water quality, enhance basin management, and equitably finance the OBMP.

The court judgement allocates groundwater rights by establishing an annual pumping "safe yield" for each Pool described above. The Operating Safe Yield (OSY) is the annual amount of groundwater that can be pumped from the Chino Basin by the Pool parties free of replenishment obligations. For planning purposes, controlled overdraft for the Appropriative Pool was not included. Annual groundwater production in excess of the OSY is allowed by the adjudication, provided that the pumped water is replaced and recharged back into the groundwater basin.

In 2011, the OSY for the basin was reassessed and was estimated to be 135,000 AFY for the period FY 2010/2011 to FY 2019/20. The next effort to recalculate the Safe Yield was recently completed in 2020 for the period FY 2020/21 to FY 2029/30 at 131,000 AFY.

As discussed in Section 1, the land use in the region has changed from primarily agricultural to primarily urban in the past several decades. It was anticipated that municipal pumping would be less than the agricultural pumping. The Chino Basin Desalters were identified as the optimal multi-benefit project to replace the expected decrease in agricultural production while also pumping and treating contaminated and high-salinity groundwater.

4.2.2.3 Chino Basin Desalter Facilities

The Chino Basin Desalters provide a local source of potable water supply through treatment of unusable groundwater. They also provide hydraulic control of the lower Chino Groundwater Basin. These facilities are critical to the continued use of recycled water in the region as well as the improvement of groundwater quality and yield in the Chino Basin. IEUA operates one of the facilities (Chino I Desalter) under contract with the CDA. The City of Chino, City of Chino Hills, and City of Ontario purchase water from the CDA.

The CDA was formed to manage the production, treatment, and distribution of highly treated potable water to cities and water agencies throughout the Chino Basin. A Joint Exercise of

Powers Agency, the CDA was formed by the Jurupa Community Services District; Santa Ana River Water Company; Western Municipal Water District; the Cities of Chino, Chino Hills, Norco, and Ontario; and IEUA to treat brackish groundwater extracted from the lower portion of the Chino Basin. Brackish water is water that has more salt [about 1,000 parts per million (ppm) of TDS] than fresh water, but not as high as seawater (about 35,000 ppm of TDS).

The Chino I Desalter was constructed in 2000 through a Joint Participation Agreement among five agencies: SAWPA, Western Municipal Water District, Orange County Water District, MWD, and IEUA. The Chino II Desalter was constructed in 2007 and provides a supplemental supply to the Cities of Chino, Chino Hills, and Ontario located within IEUA's service area as well as to the Jurupa Community Services District, City of Norco and the Santa Ana River Water Company located outside of IEUA's service area. The treatment processes at the Chino I and Chino II Desalters include RO and IX for the removal of nitrate and TDS. The treatment processes at Chino I Desalter also includes air stripping for the removal of VOCs.

These facilities serve three purposes. First, they convert unusable groundwater into a reliable potable water supply for the region and are part of a long-term pollution cleanup strategy for the Chino Basin. Second, they provide hydraulic control over the lower Chino Basin, which prevents the migration of poor-quality water into the Santa Ana River as well as downstream impacts on groundwater basins in Orange County. Third, they maintain and enhance groundwater yield for the Chino Basin.

Currently, there are 31 Chino Desalter wells with the capacity to pump about 37,600 AFY of groundwater from the southern portion of the Chino Basin, but not all wells are in operation (OBMPU 2020). Over the last 5 years, the Chino I and Chino II Desalters have produced between 28,100 and 30,000 AFY, averaging 29,200 AFY of treated groundwater combined (OBMPU 2020). IEUA retail agencies who receive water from the Desalter facilities as part of their water supply portfolios include the cities of Chino, Chino Hills, and Ontario. The Phase III expansion of the program was completed in 2016 which provided an additional 10,000 AFY of capacity. This final expansion of the system allows the Desalters to meet the 40,000 AFY pumping per the OBMP Peace Agreements. Table 4-4 shows the amount of groundwater purchased by IEUA retail agencies from the CDA for water from the Chino I Desalter over the past 5 years. IEUA retail agencies only purchase a portion of the total groundwater produced; the Western Municipal Water District also purchases groundwater from the CDA.

Table 4-4: CDA I Volume (AFY) Purchased by IEUA Retail Agencies Over Past 5 Years (DWR Table 6-8ds)

Plant Name or Well ID	Plant Capacity (AFY)	Intake Type	Source Water Type	Influent TDS	Brine Discharge	2016	2017	2018	2019	2020
Chino Desalter Authority	40,000	Open water Intake	Ground water	1,000 ppm	Brine Line	11,883	12,292	13,242	15,010	14,649
					TOTAL	**11,883**	**12,292**	**13,242**	**15,010**	**14,649**

Note: Purchased by the cities of Chino, Chino Hills, and Ontario from Chino I Desalter. These three IEUA retail agencies only purchase a portion of the total water produced by the CDA. Data from the IEUA FY 19/20 Annual Water Use Report.

4.2.2.4 Other Groundwater

Local groundwater supplies from basins other than the Chino Basin are a significant supplemental source of water for the retail water agencies within IEUA's service area. These basins include the Cucamonga, Rialto, Lytle Creek, Colton, and the Six Basins groundwater basins. The Six Basins is comprised of the Ganesha, Live Oak, Pomona, Lower Claremont Heights, Upper Claremont Heights, and Canyon Basin.

IEUA's retail agencies that use groundwater from all or some of these basins include the City of Upland, CVWD, and FWC. IEUA does not provide groundwater directly to its retail agencies.

4.2.3 Stormwater

Stormwater is water that originates during rainfall and snow melt. IEUA does not provide stormwater directly to its retail agencies. The stormwater primarily comes from surface water runoff from rain and snow that falls in the San Gabriel Mountains and moves down through the Santa Ana watershed. In undeveloped areas, the soil absorbs much of the runoff and helps retain the water within the groundwater basin. However, developed areas with a significant amount of impermeable surfaces tent to accumulate runoff in large quantities in a relatively short amount of time. Stormwater runs off roofs, through streets, and into regional storm drains, which are largely diverted into the region's flood control channels.

There are six major flood control channels spread throughout the Chino Basin region. These channels collect and manage the stormwater generated within the watershed. Major flood control channels that convey stormwater within IEUA's service area include:

- San Sevaine Creek
- Day Creek
- Deer Creek
- Cucamonga Creek
- West Cucamonga Creek
- San Antonio Creek.

Located adjacent to the channels are detention basins that are operated regionally under a multiple-use agreement for both flood control and groundwater recharge operations. IEUA, the Chino Basin Watermaster, the Chino Basin Water Conservation District and others work closely with the San Bernardino Flood Control District to maximize the amount of stormwater that can be captured and recharged into the Chino Groundwater Basin. These channels also carry dry weather runoff from excessive outdoor irrigation. Stormwater percolates to groundwater and is not utilized directly as a supply type but is counted in the volume of annual groundwater supply.

Runoff that is not captured by detention basins ultimately flows to the Santa Ana River. While there are efforts by agencies further downstream to capture these flows, large amounts of water discharge into the ocean during storm events.

4.2.4 Recycled Water and Reuse

IEUA has produced and distributed high quality recycled water since 1972 when the Agency expanded its services to include regional wastewater treatment. IEUA serves recycled water for both indirect use (outdoor irrigation, industrial processing) and groundwater recharge.

IEUA owns and operates four regional recycled water plants that produce disinfected and filtered tertiary treated recycled water in compliance with California’s Title 22 regulations. The four water recycling plants are: Regional Water RP-1, RP-4, and RP-5, and the CCWRF. These four plants treated 55,233 AF of wastewater and produced approximately 30,495 AF of recycled water during FY 2019-20. The volume not used for recycled water (24,715 AF) was discharged to the discharge locations described in Table 5-1. IEUA also owns an additional regional recycled water plant, RP-2, which only performs solids handling and is scheduled for decommissioning due to its location. More details about IEUA’s recycled water system are included in Section 5.

4.2.5 Transfers, Exchanges, and Groundwater Banking Programs

Water transfers are a water management tool used to alleviate water shortages in IEUA’s service area and the Santa Ana River Basin. Water transfers allow an agency to move or sell water from one service area to another, even when the agencies are not connected by pipelines. Water transfers can be effective during periods of severe drought or emergencies and take multiple forms to increase local reliability among agencies. The Chino Basin is a valuable resource for water transfers because it acts as a storage facility that has a capacity of up to 6 MAF.

IEUA provides imported water from MWD to WFA, CVWD, and FWC directly. WFA provides water via interconnections to Upland, Ontario, MVWD, and the City of Chino. MVWD has an interconnection that provides an annual supplemental water supply to the City of Chino Hills. In FY 19-20, MVWD sold approximately 7,707 AFY to the City of Chino Hills. Interconnections also exist between CVWD and FWC. Upland has interconnections with SAWCo, CVWD, Ontario, and Chino. The CDA’s Chino I and Chino II Desalters have interconnections with all participating agencies with a common supply with booster pumps and storage reservoirs that provide flexibility and reliability during emergencies and drought conditions. The CDA provides water to Chino, Chino Hills, Ontario, and other external agencies.

The Chino Basin Recycled Water Groundwater Recharge Program was created as part of the Chino Basin OBMP and is jointly sponsored by IEUA, CBWM, CBWCD, and the SBCFCD. The purpose of the program is to enhance water supply reliability and improve drinking water quality throughout the basin. A network of pipelines direct stormwater run-off, imported water, and IEUA recycled water to 16 recharge sites throughout the IEUA service area. These recharge basins hold the water so it can percolate into the ground and replenish the groundwater supply. Currently, only 10 of the 16 groundwater recharge basins are permitted to receive recycled water.

4.3 Historical and Current Imported Supplies

4.3.1 Metropolitan Water District

IEUA was originally formed in 1950 to act as a municipal wholesale water district in order to provide regional municipalities with imported water purchased from MWD as a supplemental source of water. Due to water quality considerations in the Chino Basin, IEUA only purchases State Water Project water from MWD for its supplies. Table 4-5 and Table 4-6 show the current and projected amount of water supplies that IEUA will have available to supply its retail agencies.

Table 4-5: IEUA Water Supplies – Actual (DWR Table 6-8)

		2020		
Water Supply	**Additional Detail on Water Supply**	**Actual Volume**	**Water Quality**	**Total Right or Safe Yield *(optional)***
Purchased or Imported Water	MWD	66,438	Raw Water	
Recycled Water	Direct Use and Groundwater Recharge	30,495	Recycled Water	
	Total	**96,933**		

Note: Recycled water supply includes recycled water for both direct use and groundwater recharge. From IEUA Annual Water Use Database and FY 19/20 Recycled Water Annual Report.

Table 4-6: IEUA Water Supplies – Projected (DWR Table 6-9)

Water Supply	Additional Detail on Water Supply	2025 Reasonably Available Volume	2025 Total Right or Safe Yield *(optional)*	2030 Reasonably Available Volume	2030 Total Right or Safe Yield *(optional)*	2035 Reasonably Available Volume	2035 Total Right or Safe Yield *(optional)*	2040 Reasonably Available Volume	2040 Total Right or Safe Yield *(optional)*	2045 *(opt)* Reasonably Available Volume	2045 *(opt)* Total Right or Safe Yield *(optional)*
Purchased or Imported	MWD	93,283		93,283		93,283		93,283		93,283	
Recycled Water	Direct Use and Groundwater Recharge	60,073		63,207		64,142		66,836		66,836	
	Total	**152,356**		**156,490**		**157,425**		**160,119**		**160,119**	

Projected Water Supply Report to the Extent Practicable (spanning header over all year columns)

Note: Purchased or Imported Water from MWD is IEUA's maximum contract amount for MWD water from Resolution 2014-12-1. Recycled Water projections from draft wastewater plant flow projections.

4.3.2 Imported Water Rates

The IEUA Board of Directors established the most recent rates for the delivery of imported water supplies on July 15, 2020. Effective July 1, 2020 and January 1, 2021, IEUA's rates for imported water are listed in Table 4-7 for the 2020, 2021, and 2022 Calendar Years (IEUA, Resolution No. 2020-7-7, July 2020).

Table 4-7: MWD Imported Water Rates

Rate Type	2020	2021	2022
Tier 1 Full Service Untreated	$755 per AF	$777 per AF	$799 per AF
Tier 2 Full Service Untreated	$842 per AF	$819 per AF	$841 per AF
WSAP Penalty[(a)]	2 X Tier 1 (100% - 115%) 4 X Tier 2 (115% or greater) Imposed by MWD		
Capacity Charge	$8,800 per cfs	$10,700 per cfs	$12,200 per cfs

Notes:

(a) Metropolitan Water Supply Allocation Plan (WSAP) Penalty rates are applied for exceedances of reduced imported water allocations from MWD caused by the adoption of a WSAP. Any penalty rates are "passed through" to the appropriate agency that caused the imposition of a penalty rate by MWD.

cfs = cubic feet per second

4.4 Planned Water Supply Projects and Programs

IEUA's Ten-Year Forecast (TYF) includes wastewater, recycled water, groundwater, stormwater, and conservation projects to enhance local supplies and reliability for the service area. These projects provide supply reliability and consist of groundwater recharge basin improvements, improving treatment and distribution of wastewater and recycled water facilities, and increasing conservation. These plans are described generally in the following sections and a summary of these projects are included in Table 4-8.

Table 4-8: IEUA's Expected Future Water Supply Projects or Programs (DWR Table 6-7)

X	Some or all the supplier's future water supply projects or programs are not compatible with this table and are described in a narrative format in this section (Section 4.4).

Name of Future Projects or Programs	Joint Project with other suppliers?	Description	Planned Implementation Year	Planned for Use in Year Type	Expected Increase in Water Supply to Supplier
Recharge Basin Improvements	Yes, Chino Basin Watermaster	See Section 4.4.5	2021	All Year Types	11,852 AF

Name of Future Projects or Programs	Joint Project with other suppliers?	Description	Planned Implementation Year	Planned for Use in Year Type	Expected Increase in Water Supply to Supplier
Water Use Efficiency Business Plan	Yes, Retail Agencies, MWD, and others	See Section 4.4.1 and Section 8	2020/2025	All Year Types	9,008 AF
Recycled Water Interties	Yes, Western Riverside County Regional Wastewater Authority	See Section 4.4.3	To be determined	All Year Types	6,000 AFY
RP-5 Liquids Treatment Expansion	No	See Section 4.4.3	2020/2025	All Year Types	See Note
RP-1 Liquids Capacity Recovery and Solids Treatment Expansion	No	See Section 4.4.3	2030/2035	All Year Types	See Note

Note: The projects and schedule detailed in this table are subject to change. Expected Increase in Water Supply is not compatible with some of these projects as they give IEUA the capacity to meet flows and do not provide water on their own. Recharge Basin improvements increase the amount of stormwater and recycled water that can be recharged to the Chino Basin.

4.4.1 Water Management Tools

Resource optimization such as groundwater recharge minimizes IEUA's reliance on imported water. Optimization efforts are typically led by regional agencies in collaboration with local/retail agencies. The 2020 WUEBP is under development, and may focus on using water more efficiently, eliminating water waste, and drought-proofing the region. The plan identifies inefficient water use within the region and provides recommended programs and tools that can be implemented by IEUA's retail agencies to continue increasing water use efficiency.

4.4.2 Transfer or Exchange Opportunities

Since IEUA receives its SWP imported water through MWD, any transfer or exchange opportunities related to SWP allocation would be coordinated by MWD. IEUA does not have any current projects or plans related to the transfer or exchange of its imported water.

The Chino Basin area itself is a large area and consists of many other water agencies outside of IEUA's retail agencies. To increase water supplies and provide flexibility, IEUA is continuing conversations amongst water agencies within the Santa Ana River Watershed and its retail agencies to further explore the opportunity to secure long-term partnerships. Various inter-agency connections would also enhance flexibility and increase reliability in local areas, as well as regional supplies. This would allow IEUA and its retail agencies to have a more robust system for aid during outages, emergencies and to optimize the use of local water supplies.

4.4.3 Non-Potable Reuse Opportunities

By emphasizing local water supply development within the service area, the region has developed and will continue to develop cost-effective supplies that reduces the dependence on imported supplies. Non-potable reuse of current supplies, as well as expansion and robust improvement of facilities and standards will further help IEUA and the region answer challenges and increase supply benefits.

One of the larger supply projects is the expansion of the liquids treatment and the construction of a wastewater solids handling facility at RP-5. The solids handling will replace the solids handling currently at RP-2, since the plant is located in a flood zone and will be decommissioned. There are also potential recycled water connections to neighboring agencies being explored to increase non-potable reuse and improve recycled water supply reliability for the region. These potential connections include extending pipelines and adding pumping facilities to serve additional recycled water to the eastern portion of its service area and the construction of a pipeline that will function as a recycled water intertie between the Western Riverside County Regional Wastewater Authority and IEUA, as well as a potential recycled water intertie between the City of Rialto and IEUA.

A future Advanced Water Purification Facility (AWPF) is also included in the TYF to ensure compliance with regulatory requirements, as well as a long-term component of regional water supply enhancement. This project was included in the IEUA Master Plan, IRP, and TYF to anticipate compliance with future standards expected in the 2030s. The project may potentially include the evaluation and forecasting of the AWPF, injection wells, and conveyance and other auxiliary facilities. IEUA is regularly monitoring its compliance metrics to address TDS and other regulatory challenges.

A liquids capacity recovery and solids treatment expansion of the Regional Water RP-1 project is expected to begin construction in FY 2026/27.

TYF recycled water projects to increase both direct use and groundwater recharge are expected to provide approximately 30,000 AFY of direct use and 18,700 AFY of groundwater recharge supply by as early as 2025.

4.4.4 Desalination Opportunities

The UWMP Act requires a discussion of potential opportunities for use of desalinated water (Water Code Section 10631[i]). IEUA operates and maintains the Chino I Desalter that is managed by the CDA. The CDA Program is a significant source of groundwater production for the region. Since the completion of the Phase III expansion project in 2016, the total pumping capacity of the CDA program is approximately 40,000 AFY of potable water. Over the last 5 years, the Chino I and Chino II Desalters have produced between 28,100 and 30,000 AFY, averaging 29,200 AFY of treated groundwater combined. In 2020, the Chino I and II Desalter’s produced approximately 30,246 AFY of treated groundwater, of which approximately 14,649 AFY was delivered to IEUA retail agencies.

The future AWPF mentioned above is also an opportunity to increase available groundwater desalination supply. Advanced treatment would sufficiently reduce the salinity of brackish groundwater and remove other possible contaminants to create additional water supply for the region.

4.4.5 Groundwater Recharge

Groundwater recharge and production are an integral part of IEUA's water system due to the substantial storage in the Chino Basin. As part of IEUA's commitment to its retail agencies and region, there are various projects working towards efficient means of groundwater production and increasing recharge capacity for the area.

As part of the Recharge Master Plan Update completed in 2013, IEUA and the CBWM evaluated 27 yield enhancing capital projects for the Chino Basin. In 2017, CBWM and IEUA approved the implementation of recharge improvements as part of the Update for the following basins: Wineville Basin, Jurupa Basin, Victoria Basin, Lower Day Basin, and Montclair Basin. The recharge improvement project design began in 2017, construction started in 2018, and project completion is expected to occur in 2020/2021. The next Recharge Master Plan Update is scheduled to be kicked off in 2021 and completed by 2023, as a collaborative effort to continue evaluating recent efforts and explore further enhancements.

In conjunction with CBWM, IEUA and retail agencies also worked with the region on the 2020 Optimum Basin Management Program Update (OBMPU). This Update includes multiple potential improvements to recycled water, groundwater, stormwater, and other existing systems. Potential improvements are outlined for existing facilities and operations and new facilities to achieve additional stormwater recharge potential alongside other program elements in the Update. IEUA has also worked with its retail agencies and the larger region to explore concepts for possible future enhancements through its Integrated Water Resources Plan and modeling effort. To answer challenges associated with groundwater contamination and increasing regulations, concepts discussed include use of turnouts as extra supply for hard reaching areas, well-head treatment, and the benefit of centralized treatment plants. These plans are currently only in the conceptual phase and may be further modeled and explored in the coming years.

4.4.6 Stormwater Management

It is widely recognized that the patterns of urban development, including hard surfacing (roads, roofs) and storm water management systems (concrete channels) have resulted in a significant reduction in natural infiltration of storm water into the groundwater within southern California and throughout the nation. CBWM estimated that the Chino Basin was losing on average about 40,000 AF of stormwater annually that previously replenished the groundwater basin because of historical patterns of development. The 2020 OBMPU identifies maximizing stormwater recharge as a primary goal for the Basin and has identified improvements to existing facilities and operations to be made. The theoretical average annual stormwater discharge available for diversion is about 74,000 AFY and the annual average stormwater recharge volume is approximately 15,000 AFY (OBMPU). In 2018, IEUA and the CBWM identified potential new stormwater recharge projects. Due to the unit cost of the new projects, which was greater that the projected cost of imported water supplied by MWD, no project was recommended for implementation at that time. The evaluation of stormwater recharge projects will again be completed in the 2021 Recharge Master Plan Update.

4.5 Effects of Climate Change

As discussed in Section 1.10.2, IEUA's service area faces hydrologic changes and uncertainty caused by the effects of climate change that may impact its water supplies. In general, the IEUA region expects an overall decrease in supply sources, caused by increased temperatures, increased intensity of extreme weather events, and shifting snowmelt and runoff patterns.

IEUA's imported water supply may be impacted by shifting snowmelt and runoff patterns that affect the capture and storage of snowmelt for the SWP. The reliability of SWP water is expected to decrease as climate change-caused precipitation changes continue. This decrease in reliability indicates a need to improve regional sustainability and decreased dependency on the SWP. In order to increase its resiliency in the face of climate change impacts, IEUA and the region plans to further develop its recycled water and local water supplies.

Local supplies are not immune to the effects of climate change, however. Local surface water supplies are dependent on precipitation and temperature, which are influenced by climate change. Extreme precipitation events can result in short periods with high volumes of runoff that will be difficult to capture, while extended droughts or dry years will result in long periods without these supplies. Higher temperatures will also cause more evaporation and transpiration, reducing the volume of water bodies such as lakes, as well as the amount of soil moisture.

Local groundwater may be adversely impacted by increased temperatures as well. Groundwater elevation and water quality may decrease during periods of drought or by the inability to capture and recharge stormwater due to increased storm intensity. Reduced rainfall and increased groundwater withdrawal may lead to more salinity buildup and increased concentrations of nitrate and other constituents, requiring the need for additional water supply for blending or investment in advanced treatment technologies (DCP 2020). Reductions in groundwater recharge caused by lower levels or precipitation or stormwater infiltration could impact the quality of the groundwater and result in regulatory violations that preclude the use of the source. A description of the water quality concerns and their possible impacts on reliability within the IEUA region is included in Section 6.

The 2018 CCAP identified recycled water supplies as a critical asset in bolstering a flexible management portfolio since these supplies are generated locally and not impacted by climate. While not directly impacted by climate change effects, applications for recycled water in the basin may become constrained if the salinity in the basin rises beyond the RWQCB's specified limits. In addition, reduced wastewater flows during drought periods due to conservation mandates may impact the volume of recycled water available for use.

The impacts of climate change of the region's water supplies are not insignificant and must be addressed to ensure the availability of sufficient water supplies. IEUA will continue assessing and addressing climate change vulnerabilities moving forward through development of its CCAP, development of its WUEBP, and participation in MWD's Local Resource Program to develop local supplies.

4.6 Reduced Delta Reliance

The Delta Plan is a comprehensive, long-term resource management plan for the Sacramento-San Joaquin Delta (Delta) that was developed as part of the Delta Reform Act of 2009 (Water code section 85000 et seq) and includes both regulatory policies and recommendations, aimed at promoting a healthy Delta ecosystem. Delta Plan Policy WR P1 [California Code of Regulations (CCR), Title 23, § 5003] is one of 14 regulatory policies in the Delta Plan. WR P1 identifies UWMPs as the tool to demonstrate consistency with state policy to reduce reliance on the Delta for any Supplier that is participating in or carrying out a proposed covered action or receiving Delta water from a proposed covered action. Within the supplier's UWMP, information should be provided that can be used to demonstrate consistency with this policy. Section (c)(1) of WR P1 states that suppliers that have (A) completed an urban water management plan, (B) implemented the efficiency measures in that plan, and (C) shown a measurable reduction in Delta reliance and improvement in regional self-reliance in the plan, are contributing to reduced reliance on the Delta and are therefore consistent with WR P1 [CCR, Title 23, § 5003(c)(1)].

IEUA is an urban water supplier and a member agency of MWD. As a recipient of imported water delivered via MWD, IEUA may indirectly receive water through a proposed project (covered action) and/or receive water from the Delta. MWD has prepared a detailed analysis that demonstrates consistency with the Delta Plan Policy (MWD 2020 UWMP, Appendix 11). In addition, IEUA has completed its own analysis, which is included in Appendix G. The analysis show that IEUA expects to increase its supplies contributing to regional self-reliance as a percent of demand by approximately 17.5% by 2045. As a recipient of water from MWD, it is infeasible for IEUA to determine the volume of its imported water supplies that come directly from the Delta. Therefore, IEUA's calculation of reduced reliance on Delta water supplies comes from MWD's regional analysis. This analysis shows that MWD's expects to reduce the percent of water supplies expected to come from the Delta by 5.2% by 2045.

In addition, this document also identifies future local supply opportunities (Section 4.3) and WUE measures (Section 8) that will increase IEUA's regional self-reliance and reduce demand for imported water. IEUA is continuing to look into local, cost-effective, and technically feasible water supply sources, as described in these sections and its WUEBP. A measurable reduction in Delta reliance and improvement in regional self-reliance can be seen from the achievements of the past 5 years of WUE and the projections for recycled water use. Over the past 5 years, IEUA's water use efficiency program has saved approximately 30,974 AF of water over the lifetime of the measure (Section 8.8). Over the next 5 years, the WUE program expects to save an additional 9,008 AF of water. By 2045, the IEUA region expects 10% of its supply to come from recycled water. Non-potable reuse is expected to increase through 2045 to 30,424 AFY and groundwater recharge is expected to increase to 16,420 AFY by 2025 and remain fairly constant through 2045 (Section 5.4). IEUA and its retail agencies remain committed to enhancing local supply and implementing water use efficiency measures to reduce their demand on imported water, thereby reducing reliance on the Delta.

Section 5: Recycled Water and Reuse

5.1 Recycled Water Planning

Recycled water opportunities have continued to grow in southern California as public education and the need to expand local water supplies continues to be a priority. Recycled water also provides a degree of flexibility and added reliability during drought conditions when imported water supplies are restricted. Recycled water is wastewater that is treated through primary, secondary, and tertiary processes and is acceptable for most non-potable water purposes such as irrigation, and commercial and industrial process water following Title 22 requirements.

IEUA began providing recycled water to customers in 1972. Initially, recycled water was delivered to a few large water users such as the Whispering Lakes Golf Course and Westwind Park in the City of Ontario, and Prado Park and Golf Course in the City of Chino.

In the early 1990s, IEUA began the construction of the first phase of the CCWRF that included treatment facilities and distribution pipelines to serve customers in Chino and Chino Hills. In conjunction with the construction of the first phase of the CCWRF, IEUA began planning for a regional recycled water delivery system to provide recycled water throughout its service area. This planning effort culminated with the completion of the IEUA Regional Recycled Water Program Feasibility Study in January 2002.

In 2004, IEUA developed a regional recycled water program implementation plan to prioritize the phased construction of the adopted 2002 Recycled Water Program Feasibility Study. This major planning effort resulted in the completion of the 2005 Recycled Water Implementation Plan (RWIP).

In 2007, IEUA developed the Recycled Water Three-Year Business Plan. The Business Plan was intended to guide the expansion of IEUA's recycled water system. The Plan focused on the most cost effective and quickest ways to increase the amount of recycled water available and used within IEUA's service area. The Plan focused on the following 3 years, to be revised and updated on an annual basis. Metrics and an annual use goal were identified for each year. Revisions/updates to the Plan were made with an FY 2010-11 update memo, the Wastewater Facilities Master Plan in 2014, the RWPS in 2015, and the IEUA FY 2015-16 Budget and Ten-Year Capital Improvement Plan (TYCIP).

More recently, the IEUA FY 2020-21 TYF, the 2018 CCAP, and the 2020 Regional Drought Contingency Plan have been used to evaluate future recycled water system projects that would benefit IEUA and its retail agencies. All three reports identified the goal of maximizing recycled water production and usage as crucial for increasing IEUA's independence from imported water supply and its resiliency during drought scenarios. As discussed in Section 2.1.2, additional studies related to wastewater flows and recycled water production are currently underway.

5.2 Regional Facilities

Regional recycled water facilities are plants, pipelines, pump stations, and reservoirs that serve recycled water to a recharge site or to more than one contracting agency. Regional facilities are constructed, owned, and operated by IEUA. Local facilities deliver recycled water from the regional facilities to customers within a contracting agency's service area and are maintained by the contracting agency. These local facilities consist mainly of pipelines (local laterals) but can also include pump stations and reservoirs. Joint regional/local facilities can be financed by IEUA to ensure timely implementation of the recycled water program. Local agencies are responsible for the planning, design, construction, and operation of local laterals and other local recycled water facilities. IEUA works closely with each agency to coordinate their recycled water planning efforts.

The regional recycled water facilities consist of a looped pipeline system that connects all four Regional Water RPs. The treated effluent from the four regional wastewater recycling effluent pump stations is delivered to the recycled water retail agencies and customers through five pressure zones, several hundred miles of pipelines, three booster pump stations, three storage reservoirs, and pressure regulating stations. The IEUA recycled water system is shown on Figure 4.

5.2.1 Wastewater Collection and Treatment

IEUA manages the Regional Sewage Service within its 242-square mile service area to collect, treat, and dispose of wastewater delivered by contracting local agencies. IEUA's facilities serve seven contracting agencies: cities of Chino, Chino Hills, Fontana, Montclair, Ontario, and Upland, and the CVWD. A system of regional trunk and interceptor sewers convey sewage to regional recycled water plants that are owned and operated by IEUA. Local sewer systems are owned and operated by local agencies.

IEUA also operates a non-reclaimable wastewater system (NRWS) that includes pipelines and pump stations that export the high-salinity industrial wastewater generated within the service area for treatment and eventual discharge to the Pacific Ocean. These water sources are not suitable for non-potable reuse. The NRWS is comprised of two separate collection systems independent of the regional wastewater system. The North System which discharges to the Sanitation District of Los Angeles County treatment facility in the city of Carson, and the South System which discharges to the Santa Ana Watershed Project Authority and the Orange County Sanitation District facility in Fountain Valley. The treated brine is then discharged to the Pacific Ocean.

5.2.2 Wastewater Treatment Plants

The wastewater collected in the regional sewer system is treated at the four RPs that IEUA owns and operates. The recycled water produced at the RPs meets Title 22 standards for non-potable reuse and groundwater recharge. All the RPs have primary, secondary, and tertiary treatment and recycled water pumping facilities that are interconnected in a regional network that IEUA also owns and operates. Effluent that is not beneficially reused from the RPs is discharged to nearby creeks that feed into the Santa Ana River where a portion of the water is recharged into the Chino Basin.

The four regional facilities are the RP-1, RP-4, RP-5, and CCWRF. RP-1 and RP-4 serve mostly the northern parts of the service area and RP-5 and CCWRF serve mostly the southern parts of the service area.

RP-1 is located in the City of Ontario and was originally commissioned in 1948. The current wastewater treatment capacity of RP-1 is 44 MGD, although it currently treats approximately 21 MGD. There are three sets of effluent pump stations that pump from RP-1 to four different pressure zones. RP-1 also has a 60 MGD biosolids treatment capacity, to treat biosolids which come from both RP-1 and RP-4. The stabilized, dewatered solids are trucked from RP-1 to the Inland Empire Regional Composting Facility for further treatment to produce Grade A compost.

RP-4 is located in the City of Rancho Cucamonga and has been in operation since 1997. RP-4 has a capacity of 14 MGD, and currently treats approximately 10 MGD. Waste sludge from RP-4 is discharged back to the sewer and flows by gravity to RP-1. RP-4 serves three pressure zones.

RP-5 is located in the City of Chino and has been in operation since 2004. The plant has a 15 MGD capacity for raw sewage and 1.3 MGD capacity for solids processing from RP-2. Currently, RP-5 is treating approximately 8.4 MGD. Ultimately, RP-5 is planned to treat up to

A MUNICIPAL WATER DISTRICT

60 MGD of wastewater and 68 MGD of solids combined from both RP-5 and the CCWRF. The disinfected effluent from RP-5 flows to a common channel where it can be discharged to a creek or pumped to a single pressure zone.

The CCWRF is located in the City of Chino and has been in operation since 1992. The plant was designed to treat up to 11.4 MGD and currently treats approximately 9.5 MGD. The removed biosolids are pumped to RP-2 for processing. RP-2 is an older plant that is owned by IEUA and is only used for solids handling. RP-2 is scheduled for decommissioning within the next 10 years. The CCWRF serves one pressure zone.

IEUA uses bypass and diversion facilities to optimize flow and capacity within the system through the San Bernardino Avenue Lift Station, Montclair Lift Station and Diversion Structure, RP-4 and CCWRF influent bypass (CCWRF influent bypass), RP-1 primary effluent diversion, and Etiwanda Trunk Line. Flows are routed between RPs to maximize recycled water deliveries while minimizing overall pumping and treatment costs. Aside from the San Bernardino Avenue Lift Station and the Montclair Lift Station, IEUA also operates the Prado Park Lift Station and RP-2 Lift Station in the sewer collection system to shift flows from one portion of the service area to another, and to pump from low points to high points.

5.3 Historical and Current Wastewater Flows

IEUA uses sewage bypass and diversion facilities to optimize the flows and capacity utilization. In general, flows are routed between plants to maximize recycled water deliveries and recharge while minimizing overall pumping and treatment costs. Currently, the regional interceptors can bypass flow from RP-4 to RP-1 and from CCWRF to RP-5. Primary effluent can also be bypassed from the RP-1 equalization basins to RP-5. The four sewer lift stations are also used to balance flows and keep water in the northern portion of the service area. Table 5-1 shows wastewater treated, recycled, and disposed of in IEUA's service area in FY 2019-20.

Over the past decade, the region has experienced increased indoor water use efficiency as a result of drought, public policy, more efficient building codes and devices, and effective conservation program campaigns. At regional facilities, this has resulted in a decrease in the volume of sewage flows of approximately 10% since 2013, as reported in the FY 2020-21 TYF. Despite this decrease, the population has increased, resulting in increased sewage strength. Even with decreasing wastewater flows, IEUA has been able to recycle more water through diversion with the Montclair and San Bernardino Avenue Lift Stations. These lift stations provide the RPs in the northern service area with more wastewater as the recycled system has been expanded and is near the groundwater recharge basins.

In FY 19-20, a total of 56,384 AF of wastewater was treated, of which 25,899 AF was discharged and 30,495 AF was recycled within the IEUA service area. The wastewater treatment and discharge volumes for FY 19-20 are included in Table 5-1.

The 2015 Wastewater Facilities Master Plan Update projections were revised in 2020 to account for reduced wastewater flows observed at the treatment plants. The revised projected wastewater flows are expected to reach approximately 56 MGD by 2040. Forecast flows are based on historical flow trends and future growth provided by contracting agencies. As discussed in Section 2.1.2, wastewater flow projections are currently being updated.

Note:
Data from FY 19/20 Recycled Water Annual Report and wastewater treatment plant flow data. Flow data is in acre-feet.

5.4 Current Recycled Water Uses

IEUA's recycled water distribution facilities consist of a pipeline network, booster pump stations, pressure regulating stations, and reservoirs as shown previously on Figure 4. These facilities allow distribution of recycled water into six pressure zones for non-potable reuse and groundwater recharge. A large transmission line connects RP-1 and RP-4 and serves the northern portion of IEUA's service area. The Edison and San Antonio Channel Pipelines were constructed to provide recycled water to areas of Ontario, Chino, and Montclair. Another transmission line ties RP-1 into RP-5 and CCWRF. Four storage reservoirs provide operational storage and have capacities varying from 3 million gallons (MG) to 5 MG. The three booster pump stations provide water from lower to higher pressure zones and three pressure reducing stations provide flow from higher pressure zones to lower pressure zones when the pressure drops below a certain point (Stantec, Recycled Water Program Strategy, April 2015). This system provides water for irrigating parks and golf courses. CCWRF's distribution system delivers water to the cities of Chino and Chino Hills.

Currently, there are over 1,300 recycled water metered connections to the recycled water distribution system. Delivered recycled water is beneficially reused for a variety of applications, including landscape and agricultural irrigation, school yards, commercial car washes and laundries, industrial process water, construction, dust control, and groundwater recharge.

A network of pipelines also directs stormwater run-off, imported water, and IEUA recycled water to 16 recharge sites throughout the IEUA service area. These recharge basins hold the water so it can percolate into the ground and replenish the groundwater supply. Currently,10 of the 16 groundwater recharge basins are permitted to received recycled water. Annually over the last 5 years, IEUA has recharged approximately 10,000 to 15,000 AF, the majority of which is recycled water.

In addition to the direct use demands and groundwater recharge program, IEUA maintains an annual base flow to the Santa Ana River at Prado Dam of up to 17,000 AF, which is currently met with recycled water. Groundwater recharge was the largest use in FY 2018/19, accounting for 41% of recycled water, followed by landscape irrigation (33%), and agricultural irrigation (21%).

In FY 2019-20, IEUA's recycled water usage was approximately 30,495 AF, of which approximately 16,278 AF was used for non-potable reuse (outdoor irrigation, industrial processes, and agriculture) by IEUA member agencies, approximately 773 AF was used directly by IEUA, and approximately 65 AF was used by San Bernardino County. An additional 13,381 AF was used for groundwater recharge. The total recycled water demand was 8% greater than FY 2018-19, with recycled water recharge up 16% and direct use up 2%. The remaining 25,889 AF wastewater not used for recharge or recycling was discharged to the Santa Ana River. Recycled water demands for the combined direct use and recharge purposes were approximately 57% of available supply, with a maximum demand of approximately 75% of available supply occurring during July through September.

Current and projected recycled water volumes through 2045 are shown in Table 5-2. Non-potable direct use is expected to increase to 27,571 AFY by 2045 and groundwater recharge is expected to increase to 16,420 AFY by 2025 and then remain constant through 2045.

Table 5-2: Current and Projected Retailers Provided Recycled Water Within Service Area (DWR Table 6-4)

Name of Receiving Supplier or Direct Use by Wholesaler	Level of Treatment	2020	2025	2030	2035	2040	2045 *(opt)*
Direct Use	Tertiary	17,115	22,880	25,742	25,742	27,771	28,271
Groundwater Recharge	Tertiary	13,381	16,420	16,420	16,420	16,420	16,420
Total		**30,495**	**39,300**	**41,297**	**42,162**	**44,191**	**44,691**

Note: 2020 value from FY 19/20 Recycled Water Annual Report. Projected values from retail agencies. No projections were made for 2045, so the projected volume is held constant from 2040. Groundwater recharge projections from IEUA projections based on groundwater recharge annual report data. 2020 Direct Use Value includes 16,278 AF from IEUA's member agencies, 773 AF used by IEUA, and 65 AF used by San Bernardino County.

The projected 2015 recycled water use from IEUA's 2015 UWMP was compared to the 2020 actual recycled water use as shown in Table 5-3. Recycled water direct use for 2020 was projected higher in 2015 than the actual recycled water direct use in 2020. The recycled water groundwater recharge volume projected for 2020 in 2015 is approximately the same as the 2020 actual recycled groundwater recharge volume. The discrepancy between the 2015 projected recycled water direct use and the 2020 actual recycled water direct use is largely due to significant land use conversions from agricultural to commercial and residential in IEUA's service area.

Table 5-3: 2015 UWMP Recycled Water Use Projection Compared to 2020 Actual (DWR Table 6-5)

	2015 Projection for 2020	2020 Actual Use
Direct Use	30,757	17,115
Groundwater Recharge	13,977	13,381
Total	**44,734**	**30,495**

Note: From 2015 IEUA UWMP and FY 19/20 Recycled Water Annual Report.

5.5 Potential and Projected Recycled Water Uses

The regional recycled water program is committed to maximizing the beneficial use of recycled water. IEUA will continue to develop, expand, and provide flexibility to allow the region to use available recycled water supplies. Expansion of the recycled water program relies on the treatment capacity of the water reclamation facilities and wastewater flow projections. IEUA's overall goal is to achieve maximum reuse of available recycled water within its service area.

5.5.1 Non-Potable Reuse

Major projects to be completed in the next 10 years are outlined in the TYF. There are several projects planned for the recycled water facilities. RP-1 projects include mechanical upgrades, effluent conveyance and flare system improvements, and energy recovery. For RP-4, process improvements, outfall repairs, and a potential plant expansion are planned for the next decade. The CCWRF has projects planned for headworks rehabilitation, aeration blower replacement, and odor control system replacement. There are no major expansion projects planned for the

CCWRF in the next 30 years. The RP-2 is located within the redefined flood zone behind Prado Dam, and since the plant does not have physical flood protection, the solids handling done at RP-2 will be relocated to RP-5 by 2023 and RP-2 will be decommissioned. RP-5 will also undergo an expansion of its liquid treatment capacity and the construction of a wastewater solids handling facility within the next 10 years. A liquids capacity recovery and solids treatment expansion of the Regional Water RP-1 project is expected to begin construction in FY 2026/27.

Another major potential project is the recycled water interties to neighboring agencies within the Santa Ana River Watershed that will increase the availability of local, resilient recycled water supplies within the IEUA service area. The construction of a pipeline that will function as a recycled water interties between the Western Riverside County Regional Wastewater Authority and the City of Rialto with IEUA are also being considered. As detailed in Section 4.4.3, a future AWPF was considered in the TYF to increase recycled water use. TYF recycled water projects to increase both direct use and groundwater recharge are expected to provide approximately 30,000 AFY of direct use and 16,420 AFY of groundwater recharge supply by 2025.

5.5.2 Indirect Potable Reuse

In conjunction with CBWM, CBWCD, and SBCFCD, IEUA conducts the groundwater recharge program within Chino Basin to replenish and maintain the Chino Groundwater Basin. Recharged water includes captured stormwater, recycled water, and imported water. The groundwater recharge projects are a means to diversify the water supply for the region and maximize the beneficial reuse of recycled water and the yield of the Chino Basin. Recycled water recharge is a key component of the region’s water supply portfolio. The more recycled water that is recharged into the Chino Groundwater Basin, the more resilient the region becomes.

5.6 Recycled Water Rates

IEUA’s recycled water volumetric rate reflects the costs associated with the operations and maintenance of its water recycling and distribution facilities, operating costs for groundwater basins, associated administration expenses, and debt service costs related to the financing of infrastructure construction. Total recycled water sales in FY19-20 were approximately $15.8 million. Adopted recycled water rates for 2019-2020 are included in Table 5-4. This table also includes the rates from the 2015 UWMP and the adopted rate for FY 20-21. A rate study will be initiated in 2021 to evaluate and provide recommendations on the future recycled water rates; FY 22-23 rates and beyond will be updated as needed based on the study and related efforts.

Table 5-4: IEUA Recycled Water Program Rates

Rate Description	2015-16	2019-20	2020-21
Direct Delivery ($/AF)	$350	$490	$490
Groundwater Recharge ($/AF)	$410	$550	$550
Effective Date	10/01/15	7/01/19	7/01/20
Deliveries (AF)	32,619	30,495	-

Notes: Current rate Resolution No. 2020-7-9 is effective through June 30, 2022.
FY 2020-21 total deliveries volume not available until July 1, 2021.

5.7 Methods to Encourage Recycled Water Use

In May 2002, IEUA's Board adopted Ordinance No. 75 establishing incentives and the mandatory use of recycled water when available. Under the provisions of Ordinance No. 75, which is consistent with the CWC Sec 13550 and the SWRCB guidelines, potential recycled water customers who do not use recycled water when it is available are subject to a 50% surcharge on their potable water rate.

IEUA also provides technical assistance to prepare necessary engineering reports and coordinate SWRCB, Division of Drinking Water (DDW) approval of recycled water use at each customer's site. IEUA has also retained experts in industrial water use and quality to assist customers in assessing operational needs associated with using recycled water.

5.7.1 Funding

Implementation of the regional recycled water program has historically been coordinated with the availability of state and federal funds to minimize use of regional capital funds. IEUA has adopted a TYF that has a budget that breaks out the federal, state, and local funding for recycled water projects. Local funding will be through the Regional Capital Fund, state grants, loans through DWR and the SWRCB, and federal grant funding through the US Bureau of Reclamation's Title XVI program.

The proposed FY 2020 TYF cost is $920.6 million, which includes water, wastewater, and recycled water projects, including the RP-1 Capacity Recovery project. The TYF is funded by a combination of pay-as-you-go, low interest State Revolving Fund loans, IEUA revenues, grants, and contributions.

Section 6: Water Quality

The quality of any natural water is dynamic in nature. This is true of local groundwater basins with the quality of water changing over the course of a year. Depending on water depth, groundwater will pass through different layers of rock and sediment and leach different materials from those strata. During periods of drought, the mineral content of groundwater increases. Water quality is not a static feature of water, and these dynamic variables must be recognized.

Water quality regulations also change. This is the result of the discovery of new contaminants, changing understanding of the health effects of previously known, as well as new contaminants, development of new analytical technology, and the introduction of new treatment technology. All water purveyors are subject to drinking water standards set by the U.S. Environmental Protection Agency (EPA) and the SWRCB DDW.

Planning efforts of IEUA, the CBWM, and retail agencies emphasize the importance of water quality. The region generally enjoys good water quality, but isolated areas of poor quality require blending of certain water sources or treatment to meet drinking water standards. Significant increases in the use of groundwater, recycled water, and demineralized groundwater can reduce reliance on imported MWD water and increase focus on local water quality monitoring. It is projected that a significant portion of urban water demand will continue to be met using Chino Basin groundwater. Thus, the discussion of water quality focuses primarily on water quality in the Chino Basin.

This section provides a general description of the water quality of the local supplies, the Chino Basin supply, and a discussion of potential water quality impacts on the reliability of these supplies.

6.1 Local Supplies

Local water supplies include surface water from nearby mountain streams, recycled water from IEUA treatment plants, recovered groundwater from the Chino Basin Desalters, and groundwater extracted from the Chino Basin and other groundwater basins in the area.

6.1.1 Surface Water

Surface water from local sources that originate in the San Antonio Canyon, Cucamonga Canyon, Day Creek, Deer Creek, Lytle Creek, and other smaller surface streams is generally of high quality since these creeks are fed by snowmelt and other precipitation in the San Gabriel Mountains. Surface water sources are treated prior to introduction to the potable water supply to ensure bacteriological quality and compliance with state and federal water quality standards.

6.1.2 Recycled Water

Recycled water holds the greatest potential as a new source of supply in the Chino Basin and in the southern California region as a whole. By the year 2045, direct recycled water use is projected at 27,571 AFY and another 16,420 AFY of recycled water will be used for groundwater replenishment.

All IEUA water recycling treatment plants produce recycled water suitable for full body contact recreation and generally meet the more stringent aquatic habitat criteria. The continued use of recycled water is driven by compliance with regulatory limitations for IEUA's recycled water and groundwater recharge operations. In the event of non-compliance, assets would become stranded and IEUA would need to supplement its water supply portfolio with more expensive and/or less reliable sources. Numeric limitations for TDS are imposed upon recycled water and groundwater recharge. In addition, an ambient water quality TDS concentration, a statistical construct that represents an estimate of the volume-weighted TDS concentration of groundwater, is established to determine the assimilative capacity within the basin.

The ambient TDS concentration in the Chino Basin groundwater has been gradually increasing over the past several years, due to climate change, conservation, and drought periods, thus reducing the basin's assimilative capacity. In addition, emerging contaminants of concern, such as 1,2,3-Trichloropropane (1,2,3-TCP), perfluorooctanoic acid (PFOA), and microplastics could impact IEUA's ability to maximize recycled water use. The April 2020 Regulatory Challenges memorandum prepared by IEUA evaluates water quality regulatory challenges for the future of its water supply.

During the 2012 to 2016 drought, the 12-month running-average TDS concentration in recycled water approached the permit limit for TDS due to an increase in TDS concentration from water supplies used by retail agencies and indoor water conservation. The Regulatory Challenges memorandum estimated that, without taking additional action, TDS limit for recycled water use may be exceeded within the next 10 years. IEUA and the CBWM petitioned the RWQCB to consider updating the maximum-benefit Salt and Nutrient Management Plan to incorporate a revised compliance metric for recycled water TDS and nitrate to allow a longer-term averaging period, which would provide an average concentration that is less susceptible to exceedances during drought. This evaluation is currently ongoing. As of the last annual report, submitted in April 2019, the TDS and nitrate maximum concentration limits have never been exceeded; however, the IEUA-established "trigger limit", which is 20 milligrams per liter (mg/L) below the permit limit and triggers a water quality evaluation, was reached in 2015.

Poly- and per-fluorinated compounds (PFAS) are known to be present in recycled water and any new regulatory standards for PFAS could impact the ability to reuse recycled water without treatment. 1,2,3-TCP is a chlorinated hydrocarbon with high chemical stability that is very persistent in groundwater and the regional water recycling facilities IEUA operates were not designed to remove it. During 2019, recycled water used for groundwater recharge exceeded the 1,2,3-TCP maximum contaminant limit (MCL) and PFOA notification level (NL) and went into an accelerated monitoring schedule for 16 weeks. Corrective action reports were submitted to the DDW and RWQCB in February 2020 and source evaluation for both compounds is ongoing. Advanced treatment may be required to meet future regulations of these two contaminants.

Finally, there are other contaminants of emerging concern, such as microplastics, which are likely to emerge over the next 10 years which could also require advanced treatment to continue recharge of recycled water, further underscoring the need for advanced treatment in the region.

Based on these water quality trends, IEUA has concluded that the implementation of AWPFs may likely be required to address increasing salinity in the 2030s. Though there are a number of solutions that IEUA could implement to address groundwater quality challenges, none are as optimal as the implementation of advanced treatment. Advanced treatment would address TDS levels for both direct use and groundwater recharge while also addressing contaminants of emerging concern. In addition, advanced water purification has the potential to be integrated into future recycled water uses, such as direct potable reuse.

6.1.3 Treated Groundwater

Treated groundwater from the Chino Desalters 1 and 2 is very high quality since it is treated by RO, IX, and air stripping. Groundwater from the lower part of the Chino Basin is treated by the desalters, as it has high TDS and nitrate concentration. TDS and nitrate are reduced by the RO process and nitrate concentration is further reduced by the IX process. Two of the Chino Desalter 2 expansion wells are being used to capture groundwater contaminants from the South Archibald plume. Some of the groundwater wells for Desalter 1 have been impacted by a VOC plume located near the Chino Airport. VOCs are removed by an air stripping facility at Desalter 1. Other identified plumes (CIM plume and an Ontario Airport Plume) could impact desalter wells and increase treatment needs. The operation of the Chino Desalters 1 and 2 is a critical component of maximum benefit commitments under the Basin Plan and a long-term salinity management strategy that enables the region to use recycled water within the Chino Basin.

6.1.4 Other Groundwater Basins

Limited information is available on water quality from the groundwater basins surrounding Chino Basin. Most of the basins have elevated concentrations of nitrate. Use of these local groundwater supplies by retail water agencies for potable water supply suggests that any present water quality issues can be resolved by blending or well head treatment.

6.1.5 Imported Water

MWD supplies about half the water used in southern California from its two main sources of water: 1) water from the SWP delivered via the California Aqueduct and 2) water from the Colorado River delivered via the Colorado River Aqueduct. The TDS in the Colorado River water averages about 700 mg/L during normal water years. Water supplies from the SWP have significantly lower TDS levels, averaging 275 mg/L. IEUA’s service area is a SWP-exclusive area, only importing MWD water from the SWP in order to meet TDS objectives in the Chino Basin.

Other major water quality concerns include:

- Perchlorate in local groundwater supplies
- Hexavalent chromium in groundwater
- 1,2,3-TCP in groundwater
- Disinfection by-products.

6.2 Chino Basin Groundwater Quality

Chino Basin groundwater is a critical resource to the entire Santa Ana River Watershed. The Chino Basin Watermaster performed monitoring of over 600 wells in the period from 1999 to 2001 to establish a baseline of groundwater quality for the basin to assist with the implementation of the Optimum Basin Management Program. Groundwater quality data has been obtained periodically since 1990. Since 2000, the Chino Basin Watermaster has assessed groundwater quality in the basin using data compiled through its own monitoring activities and the efforts of other cooperating entities, and has reported on the water quality trends and findings related to regulated contaminates and contaminants of emerging concern in a biannual State of the Basin report. The water monitoring program has been periodically refined as needed to support the detection of water quality anomalies and contaminants of concern.

The most recent groundwater quality data comes from sampling done over the 5-year period from July 2013 to June 2018. This included 141 "active municipal supply wells" (wells that pumped groundwater anytime during 2017 or 2018), other municipal supply wells not determined to be active, and private agricultural, non-agricultural, and monitoring wells, whether recently active or not.

From these groundwater monitoring results, the three most common contaminants that exceed a primary MCL in the Chino Basin at active municipal wells are nitrate (71 wells), 1,2,3-TCP (33 wells), and perchlorate (27 wells). Of the recently active 141 municipal supply wells, 45 have at least one drinking water contaminant, 17 wells have two contaminants, 14 have three contaminants, five have four contaminants, and five have five contaminants. The wells with drinking water contaminants are located in the southern (south of the 60 freeway) and western (west of Euclid Avenue) areas of the basin. Of the 141 recently active municipal supply wells, only two wells shown an exceedance of a California NL for 1,4-dioxane. There may be additional exceedances for 1,4-dioxane and other contaminants, but since the monitoring of contaminants with an NL is not required by DDW or testing may be performed using analytical methods with the lowest detection limits that are greater than the NLs. Table 6-1 and Table 6-2 provide a summary of active municipal supply wells with exceedances of primary MCLs and NLs.

Perchlorate and hexavalent chromium are also the two contaminants characterized in the basin that are undergoing review and consideration by the DDW for a primary MCL revision.

Table 6-1: Summary of Drinking Water Contaminants with Primary MCLs

Analyte	Primary CA MCL	Number of Active Municipal Supply Wells with Exceedance of MCL	Number of Municipal Supply Wells with Exceedance of MCL	Number of Total Wells in the Chino Basin with Exceedance of MCL
Nitrate-Nitrogen	10 mg/L	71	80	553
1,2,3-Trichloropropane	0.005 μg/L	33	36	111
Perchlorate	6 μg/L	27	30	387

Analyte	Primary CA MCL	Number of Active Municipal Supply Wells with Exceedance of MCL	Number of Municipal Supply Wells with Exceedance of MCL	Number of Total Wells in the Chino Basin with Exceedance of MCL
Trichloroethylene (TCE)	5 µg/L	11	14	269
Gross Alpha	15 pCi/L	6	7	14
Chromium	50 µg/L	4	4	4
Arsenic	0.01 mg/L	3	5	74
1,2-Dibromo-3-chloropropane	0.2 µg/L	3	3	4
Tetrachloroethene (PCE)	5 µg/L	3	3	96
Trihalomethanes	10 µg/L	2	3	2
Nitrite-Nitrogen	1 mg/L	2	2	17
1,1-Dichloroethene (1,1-DCE)	5 µg/L	1	1	13
Dichloromethane (Freon 39)	5 µg/L	1	1	91
Uranium	20 pCi/L	1	1	1

Notes: Data collected for FY 2013/2014 to FY 2017/2018. "Active" Municipal supply wells are those that have been pumped at least once during the years 2017 and 2018.
µg/L = micrograms per liter; pCi/L = picocuries per liter

Table 6-2: Summary of Drinking Water Contaminants with Notification Levels

Analyte	CA Drinking Water NL	Number of Active Municipal Supply Wells with Exceedance of NL	Number of Municipal Supply Wells with Exceedance of NL	Number of Total Wells in the Chino Basin with Exceedance of NL
1,4-Dioxane	1 µg/L	2	2	133
Manganese	0.5 mg/L	0	0	118
N-Nitroso dimethylamine (NDMA)	0.01 µg/L	0	0	60
Vanadium	0.05 mg/L	0	0	55
Naphthalene	0.017 mg/L	0	0	48
1,2,4-Trimethylbenzene	0.33 mg/L	0	0	26
1,3,5-Trimethylbenzene	0.33 mg/L	0	0	19
Methyl Isobutyl Ketone	0.12 mg/L	0	0	11
n-Propyl benzene	0.26 mg/L	0	0	11
HMX (Octogen)	0.35 mg/L	0	0	11
Chlorate	0.8 mg/L	0	0	4

Analyte	CA Drinking Water NL	Number of Active Municipal Supply Wells with Exceedance of NL	Number of Municipal Supply Wells with Exceedance of NL	Number of Total Wells in the Chino Basin with Exceedance of NL
formaldehyde	0.1 mg/L	0	0	3
N-Nitrosodiethylamine (NDEA)	0.01 μg/L	0	0	3
Ethylene Glycol	14 mg/L	0	0	1
n-Butylbenzene	0.26 mg/L	0	0	1

Note: Data collected for FY 2013/2014 to FY 2017/2018. "Active" Municipal supply wells are those that have been pumped at least once during the years 2017 and 2018.

6.2.1 1,2,3-TCP

The occurrence of 1,2,3-TCP in nearly 25% of active municipal supply wells is noteworthy. The MCL for 1,2,3-TCP is 0.005 micrograms per liter (μg/L), which is 5 parts per trillion (ppt). This is the lowest numerical value for a MCL established to date in California. Unlike newly adopted MCLs, the MCL for 1,2,3-TCP became immediately effective upon its adoption in December 2017, requiring municipal water agencies to either cease using active wells with 1,2,3-TCP concentrations in excess of the new MCL immediately or implement treatment or blending to ensure their water supplies have concentrations below the MCL. Before 2018, municipal water supplies were not routinely tested for 1,2,3-TCP, or when testing occurred it was not always done using the lowest available detection limit. For this reason, the DDW also required municipal water agencies to perform quarterly compliance monitoring in 2018 using laboratory detection limits low enough to test for concentrations equivalent to the MCL of 0.005 μg/L. The wells producing 1,2,3-TCP concentrations equal to or greater than the MCL are primarily located in the western half of the Basin. At least three agencies within the IEUA service area have had to shut down supply wells or modify operations as a result of the new MCL.

6.2.2 Perchlorate

An MCL of 6 μg/L was established in 2007. The Public Health Goal (PHG) for perchlorate was reduced from 6 μg/L to 1 μg/L in 2015 after scientific literature indicated the possible health effects to infants from exposure to perchlorate in drinking water. The DDW thereby lowered its required detection limit for the purposes of reporting from 4 μg/L to 1 or less μg/L to gather state-wide data to determine whether a revision to the MCL is warranted.

Over the 5-year period of measurement, 49% of the wells in the Chino Basin had a 5-year maximum concentration that exceeds the MCL of 6 μg/L and 95% of the detectable concentrations of perchlorate in the basin were above the PHG of 1 μg/lL Perchlorate is prevalent throughout the basin. If the MCL were lowered from 6 μg/L, treatment facilities could be required across most of the Chino Basin.

6.2.3 Hexavalent Chromium

Hexavalent Chromium (Chromium VI) is produced from by-products of industrial applications and the manufacturing of stainless steel and other alloys as well as occurring naturally in some locations. The PHG for Chromium VI is 0.02 μg/L. In 2013, DDW adopted an MCL for Chromium

VI of 10 μg/L, which was then challenged in court. In 2017, a judgment was issued invalidating the Primary MCL for drinking water since there was no consideration of the economic feasibility of complying with it. The court ordered DDW to conduct an economic evaluation and establish and adopt a new MCL, which could be the same or different from the now invalidated MCL of 10 μg/L. 7% of all wells sampled in the basin have a concentration above 10 μg/L; 127 of the 141 municipal wells have detectable concentrations of Chromium VI, and nine of the 141 active municipal wells exceeded 10 μg/L. Hexavalent chromium is not a widespread compliance issue based on the 10 μg/L, but compliance could be problematic in the future if a new, lower MCL is established.

6.2.4 Poly- and Per-fluorinated Compounds

In 2009, the EPA published provisional Health Advisory Levels (HALs) for perfluorooctanoic acid (PFOA) and perfluorooctane sulfonate (PFOS) of 400 nanograms per liter (ng/L) and 200 ng/L, respectively. In 2016, the EPA significantly lowered the HAL for PFOA and PFOS to a combined 70 ng/L and in 2018, the DDW established NLs for PFOA and PFOS of 14 and 13 ng/L, respectively. The majority of wells in the Chino Basin have not been sampled for either of these contaminants. The 30 wells that have been sampled were tested in 2015 using laboratory detection limits of 20 and 40 ng/L, which is higher than the current NLs. Monitoring or recycled water recharge blending sources shows that many of the sources have detectable concentrations of PFOA and PFAS, some of which are above the NLs. The EPA and DDW have indicated that they are moving forward with adopting MCLs for PFOA and PFAS in the near future. The occurrence of these contaminants in Chino Basin groundwater as of March 2019 is not well characterized and there are recharge water sources with concentrations above the NLs. Widespread monitoring is necessary to understand the occurrence of PFOA and PFAS in the basin to plan for compliance with potential future drinking water regulations.

6.2.5 Total Dissolved Solids and Salts

During the development of the 2000 OBMP, IEUA and the Watermaster recognized that implementing a recycled water recharge and reuse program would require large scale treatment and mitigation of salt loading for TDS and nitrate. The Watermaster and IEUA petitioned the RWQCB to establish a maximum benefit-based salt and nutrient management plan that involved increasing the TDS and nitrate objectives for the Chino-North groundwater management zone (GMZ) to numerically higher value to enable recycled water reuse without mitigation or treatment. The plan included the implementation of a monitoring, analysis, and reporting program, the construction and future expansion of the Chino Basin Desalters to attain hydraulic control of the GMZ to protect the Santa Ana River, the construction of recharge facilities to increase storm and recycled water recharge, and a commitment to future treatment of recycled water or groundwater, as needed, to protect beneficial uses and comply with the maximum benefit TDS and nitrate objectives. The maximum benefit SNMP was incorporated into the Basin Plan in January 2004.

TDS has a California secondary MCL of 500 mg/L. Over the 5-year period from July 2013 to June 2018, 61% of wells measured had 5-year maximum values exceeding the MCL. The average and median values were 778 and 614 mg/L, respectively. The wells with the highest TDS concentrations are predominantly located south of Highway 60 in the area of historical and current agricultural land uses. It is expected that TDS concentrations in the basin will increase over time since it is operated as a closed basin.

Nitrate has a primary MCL of 10 mg/L. Over the 5-year period, 68% of the wells measured had 5-year maximum values exceeding the MCL. The average and median values were 26 and 17 mg/L, respectively. As with TDS, the wells with the highest nitrate concentrations are located in the historical and current agricultural land use areas.

6.2.6 Other Contaminants

There are other active municipal supply wells with exceedances of primary MCLs in the IEUA service area, as listed in Table 6-1, including trichloroethylene (TCE), gross alpha, chromium, arsenic, 1,2-dibromo-3-chlorpropane, tetrachloroethene (PCE), trihalomethanes, nitrite-nitrogen, 1,1-dichloroethene (1,1-DCE), dichloromethane (Freon 39), and uranium. The percentage of wells with 5-year maximum concentrations exceeding the primary MCLs for some of these contaminants are 14% for arsenic, 26% for TCE, 10% for PCE, and 6% for 1,2-DCA.

The number of active municipal wells with exceedances for any of these contaminants is less than 11, indicating they are not widespread compliance issues. However, these contaminants should be observed, and planning should be conducted to ensure the ability to adapt to any increases in the number of wells with exceedances or changes to MCLs for these contaminants that could cause future water supply issues.

6.3 Water Quality Impacts on Reliability

Maintaining the quality of the groundwater and other water supply increases the reliability by ensuring that deliveries are not interrupted due to water quality concerns. A direct result from the degradation of any water supply is increased treatment cost before consumption. The poorer the quality of the source water, the greater the treatment cost. Water may degrade in quality to the point that it is not economically feasible for treatment. In this scenario, the degraded source water is taken off-line. This in turn can decrease water supply reliability by potentially decreasing the total supply and increasing demands on alternative water supplies.

Groundwater quality impairment has impacted significant supplies across the basin. Including CDA, approximately one-third of existing groundwater supply capacity is currently offline due to impairment or requires clean water for blending purposes to meet water quality regulations. Water quality issues are constantly evolving, and IEUA will have to continue to take action to protect and treat water supplies when needed. Potential future impacts to water supply reliability could be caused by increasing TDS concentration in recycled water, revisions on DDW MCLs, and changes in contamination plume characteristics.

The use of recycled water could become more difficult in the future because the ambient TDS concentration in the Chino Basin groundwater is increasing, thereby reducing assimilative capacity. Increases in TDS concentration from water supplies used by retail agencies and from the SWP could further increase the TDS concentration of recycled water, especially if coupled with an increase in indoor water conservation.

The Watermaster monitors and delineates the extents of the contaminant plumes located in the basin, including the Chino Airport and South Archibald plumes, General Electric Test Cell and Flatiron plumes, the former Kaiser Steel Mill Facility plume, the California Institution for Men plume, the Stringfellow plume, and the Milliken Landfill plume. Currently, the Chino Airport and South Archibald plumes are undergoing remedial strategies using the Chino Basin Desalters for pumping and treating the contaminated groundwater. Any subsequent movement of contaminant plumes could affect additional groundwater wells and the water supply of the basin, and therefore, the water supply reliability of IEUA.

Changes in DDW MCL values can also affect groundwater supply in the Chino Basin. The adoption of an immediately effective MCL for 1,2,3-TCP as discussed above resulted in the cessation of use of wells with concentrations in excess of the new MCL. Some supply wells were shut down or had to modify their operations due to this new MCL. The EPA is currently developing MCLs for PFOA and PFOS. Given that recycled water used for groundwater recharge exceeded the PFOA notification level in 2019, a newly established MCL would impact the ability to use both recycled water and groundwater sources. Similarly, revisions in primary MCL values for perchlorate and hexavalent chromium could cause compliance issues in the future if new, lower MCLs are established. Prolonged reductions in groundwater pumping due to groundwater contamination could reduce the safe yield and potentially contribute to the loss of hydraulic control and the spread of contamination in the basin. It will become increasingly necessary to pump and treat groundwater to comply with drinking water standards and maintain Safe Yield and hydraulic control of the basin.

Section 7: Reliability Planning

7.1 Overview

The UWMP Act requires urban water suppliers to assess water supply reliability that compares total projected water use with the expected water supply over the next 20 years in 5-year increments. The UWMP Act also requires an assessment for a single-dry year and multiple-dry years. Water Code section 10635(b) is a new requirement for the 2020 UWMPs and requires suppliers to prepare a drought risk assessment, which enables suppliers to evaluate their risk under a severe drought period lasting for 5 consecutive years starting in 2021. This section presents the reliability and drought risk assessments for the IEUA service area.

7.2 Supply Challenges

As discussed throughout this document, especially in Sections 2, 4, 5, and 6, supply can be affected by a variety of factors, including water quality regulations and climate change impacts. Some sources are more vulnerable to seasonal or climatic shortage than others. The supply challenges for each of the region's water sources are discussed in this section. A summary of the factors that may result in inconsistency of supply for each source in IEUA's service area are included in Table 7-1.

Table 7-1: Factors Resulting in Inconsistency of Supply

Water Supply Source	Legal	Environmental	Water Quality	Climatic
Local Surface Water	None identified.	None identified.	None identified.	Shifting precipitation patterns; reduced snowpack; increased evaporation.
Stormwater	None identified.	Increases in impervious surfaces.	Storm water quality may require treatment prior to infiltration	Reduced infiltration rates and stormwater capture.
Chino Basin Groundwater	Development of new MCLs for contaminants present in the basin.	Safe yield operating constraints.	Contaminants exceeding MCLs.	Changes in rainfall frequency and intensity; impacts to recharge and runoff.
Other Groundwater	Development of new MCLs for contaminants present.	Safe yield operating constraints.	Contaminants exceeding MCLs.	Reduced natural infiltration.

Water Supply Source	Legal	Environmental	Water Quality	Climatic
Chino Basin Desalter	Groundwater replenishment obligation.	None identified.	Shifts in contaminant plume characteristics or location.	None identified.
Recycled Water	Changes in water quality requirements.	None identified.	Increasing TDS levels. See Legal.	Reduction in amount of wastewater and impacted by increase in imported water TDS during drought periods
Imported Water	Potential cutbacks.	None identified.	Disinfection byproduct precursors; arsenic; nutrient levels.	Shifts in precipitation patterns; reduced snowpack; and potential for increased TDS in drought periods

7.2.1 Local Surface Water

Local surface water is impacted by climate due to its dependence on precipitation and snow melt. Changes in precipitation patterns and earlier snow melt due to increased temperatures will affect local surface water both in quantitatively and temporally. Higher temperatures could also result in increased evaporation of soil moisture or exposed water bodies, reducing surface water supplies. Surface water supplies are also highly variable on a yearly basis.

Surface water is generally of high quality and is anticipated to be unaffected by water quality changes.

7.2.2 Stormwater

Increases in temperature and evaporation rates can dry out soil, resulting in increased water runoff as water is unable to penetrate dry soil. Climate change is expected to cause higher intensity rainfall storms on a more infrequent basis, which could also reduce the amount of stormwater runoff able to be captured. Annual snow melt patterns are also expected to change, which could affect water supply planning and stormwater capture.

Other challenges include reductions in natural infiltration into the ground due to channelization, new development, increased outdoor water efficiency, and open space conversion. Construction of additional stormwater recharge facilities may be limited in the highly urbanized service area. Water quality of stormwater may require treatment, especially in green infrastructure, integrated with stormwater recharge facilities.

7.2.3 Chino Basin Groundwater

Chino Basin groundwater supplies are dependent on rainfall and supplemental sources for recharge, as well as the ability of soil to absorb water during rainfall events. These dependencies make this groundwater supply vulnerable to climate change impacts, such as warmer temperatures and drought increasing the dryness of soil, resulting in less absorption and an increase of water runoff instead of percolation through the soil. Chino Basin groundwater supplies are not impacted by climate once the water is stored in the groundwater basin.

As discussed in Section 6, there are several common contaminants that exceed primary MCLs or NLs in the basin at active municipal wells, including nitrate, 1,2,3-TCP, perchlorate, hexavalent chromium, and 1,4-dioxane. Increases in the prevalence of these, and other contaminants, may result in the closure of supply wells which would impact water supply reliability. In addition, the use of recycled water could become more difficult in the future due to increasing TDS concentration in the groundwater. Finally, any changes in or development of new MCLs or other legislative concentration requirements would affect groundwater supply.

7.2.4 Other Groundwater

Climate effects on non-Chino Basin groundwater is expected to be similar to those identified for the Chino Basin, including a reduction in reduced natural infiltration, safe yield operating constraints, and water quality issues.

7.2.5 Chino Basin Desalter

Water supply from the Chino Basin Desalters is not affected by climate change, but may be affected by the outstanding obligation for groundwater replenishment to the Chino Basin through the duration of the Peace Agreement and the high energy needs and costs of the treatment of brackish water and brine disposal. In addition, any changes or movement of the contaminant plumes that are being treated by the Desalters could affect nearby groundwater wells or result in increased treatment costs.

7.2.6 Recycled Water

Recycled water holds the greatest potential as a source of reliable supply in the IEUA service area. Recycled water is the most climate resilient water supply available to the region as wastewater flows were shown not to be impacted by climate according to the 2015 IEUA IRP. However, since the service area's water supply can include 20 to 30% of SWP imported water, droughts have resulted in higher salinity levels in source water supply, which directly impacts the salinity in the treated recycled water. Additionally, increases in more efficient indoor water use may reduce the amount of wastewater available for recycled water in the future.

Recycled water is also vulnerable to increasingly strict regulatory and environmental issues related to the construction and operation of recycled water systems, especially the high amount of energy consumption required in recycled water treatment. Recycled water requires the highest level of treatment to meet Title 22 water quality requirements, which can be very energy intensive.

7.2.7 Imported Water

Changing climate patterns are expected to shift precipitation patterns and affect water supply. The areas of concern for California include a reduction in Sierra Nevada Mountain snowpack, increased intensity and frequency of extreme weather events, rising sea levels causing increased risk of Delta levee failure, seawater intrusion of coastal groundwater basins, and potential cutbacks on SWP to meet ecological and other needs. The major impact in California is that without additional surface and groundwater storage, the earlier and heavier runoff (rather than snowpack retaining water in storage in the mountains), will result in more water being lost to the oceans. A heavy emphasis on storage is needed in the State of California.

MWD is responsible for providing high quality potable water throughout its service area. Over 300,000 water quality tests are performed per year on MWD's water to test for regulated contaminants and additional contaminants of concern to ensure the safety of its waters.

The key water quality issues for SWP waters are disinfection byproduct precursors, in particular, total organic carbon and bromide. Disinfection byproducts result from total organic carbon and bromide in the source water reacting with disinfectants at the water treatment plant. MWD has resolved these treatment restrictions by using ozone disinfection at its treatment plants. All MWD's treatment plants currently have ozone treatment facilities.

Arsenic is also of concern in some groundwater storage/transfer programs that MWD participates in. Groundwater inflows into the California Aqueduct are managed to comply with water quality regulations and protect downstream water quality while meeting supply targets. Additionally, nutrient levels in SWP system are relatively high, leading to the potential for algal related taste and odor issues that can affect water management strategies. MWD is engaged in efforts to protect the quality of SWP water from potential increases in nutrient loading from wastewater treatment plants (MWD, 2020 UWMP, June 2021).

Imported SWP water is an important water supply source for the water agencies in the Chino Basin, and its TDS concentration is an important consideration in the salt and nutrient management plan in the Basin Plan. The TDS concentration in SWP water at Lake Silverwood, the point from which SWP water is distributed to the Chino Basin, has historically varied from 74 to 430 mg/L, with the lower TDS concentrations associated with above normal to wet hydrologic conditions and the higher TDS concentrations associated with below normal to dry hydrologic conditions.

7.3 Supply and Demand Comparisons

IEUA's service area relies on a variety of supply types, as detailed above. The available baseline water supply projections for the entire IEUA region by source type are included in Table 7-2 below. The imported water supply type is broken into imported water to be supplied by IEUA via MWD and imported water delivered to IEUA retail agencies from other wholesale agencies.

While this summary of baseline regional water supply sources is useful for IEUA's planning purposes, the reliability assessment was completed using only supplies/demands for imported water from MWD and IEUA recycled water, as these are the water supply sources that IEUA manages. Each retail agency is completing its own reliability assessment which are included in their respective 2020 UWMPs. IEUA's ability to satisfy demands during three scenarios: a normal water year, single-dry year, and multiple-dry years was completed and described in the following sections.

The available imported water supply is not expected to decrease or change for these years due to the redundancy and reliability provided by MWD's extensive storage and water management system. As discussed in MWD's 2020 UWMP, MWD does not anticipate a shortfall in water supply for any of the dry year scenarios. While the California Aqueduct supplies are anticipated to decrease during dry years, overall, MWD does not expect any shortfall due to their diligent efforts to increase resiliency to drought over the past several years by using off-stream storage and other means. While IEUA only receives water from the California Aqueduct, they still expect to receive up to their full contract amount for both single dry and multiple dry years. The recycled water supply is not expected to dramatically decrease during drought periods; however, there are some slight fluctuations due to changes in water use behaviors during drought periods.

Since imported water is expected to be available during all year types, the basis of water year data that was used for the reliability assessment is therefore based on recycled water conditions. The average year supply is the average recycled water supply (total wastewater plant effluent flows) for FY 15/16 through FY 19/20. The single dry year supply basis is the wastewater treatment plant flows during FY 15/16, a hydrologically dry year with relatively low wastewater plant flows. This year was one of the last years of California's historic 2011-2017 drought, when almost 80% of the state was in a state of severe drought from 2013 through 2017 (National Oceanic and Atmospheric Administration, n.d.). The basis water years were limited to the past 5 years to accurately account for the growth in recycled water supply and demand that has occurred. The multiple dry year supply basis is based on repeated FY 15/16 conditions. Table 7-3 shows the basis of water year data used to define each scenario. The single and multiple dry year percentage of average supply was used as a multiplier to calculate the reduced volume of supplies available in the single dry and multiple dry years scenario. Since recycled water is not strongly influenced by drought periods, the available supply during the dry year scenarios is just 26 AF less than the average year supplies, which rounds to 100% of average year supplies.

Table 7-2: Projected Regional Baseline Water Supply Sources

Supply Type	2020	2025	2030	2035	2040	2045
Imported Water – IEUA	66,438	92,928	94,928	96,928	98,928	98,928
Imported Water – Other	17,667	10,728	10,728	10,728	10,728	10,728
Chino Basin Groundwater	51,749	63,129	72,822	78,441	89,776	92,080
Other Groundwater	26,436	27,060	27,171	27,282	27,394	27,505
Surface Water	16,652	10,089	10,089	10,089	10,089	10,089
Recycled Water - Direct Use	16,278	23,932	25,929	26,794	28,823	29,323
Recycled Water - Groundwater Recharge	13,381	16,420	16,420	16,420	16,420	16,420
Chino Basin Desalter	14,649	17,733	17,733	17,733	17,733	17,733
Water Use Efficiency	3,292	9,788	11,984	17,257	22,570	27,802
TOTAL	**226,542**	**271,807**	**287,804**	**301,672**	**322,461**	**330,608**

Note: Roll up of retail agency projections except for 2020, which are actual values. SAWCo is not included in the table because transfers from SAWCo are reported within receiving member agency values. The values in this table match the retail agency water supplies shown in Table 4-2, with the additional inclusion of recycled water for groundwater recharge and water use efficiency as supply sources. For the "Imported water – IEUA" supply, water purchases in excess of Tier 1 allocation of Resolution 2014-12-01 will be assessed at the Tier 2 rate.

Table 7-3: IEUA Service Area: Basis of Water Year Data (Reliability Assessment) (DWR Table 7-1)

		Available Supplies if Year Type Repeats	
			Quantification of available supplies is not compatible with this table and is provided elsewhere in the UWMP Location:
		X	Quantification of available supplies is provided in this table as either volume only, percent only, or both.
Year Type	**Base Year** *If not using a calendar year, type in the last year of the fiscal, water year, or range of years, for example, water year 1999-2000, use 2000*	**Volume Available (acre-feet)**	**% of Average Supply**
Average Year	FY 15/16 - FY 19/20	147,503	100%
Single-Dry Year	FY 15/16	147,477	100%
Multiple-Dry Years 1st Year	FY 15/16	147,477	100%
Multiple-Dry Years 2nd Year	FY 15/16	147,477	100%
Multiple-Dry Years 3rd Year	FY 15/16	147,477	100%
Multiple-Dry Years 4th Year	FY 15/16	147,477	100%
Multiple-Dry Years 5th Year	FY 15/16	147,477	100%

Note: Average year is the average of FY 15/16 through FY 19/20 wastewater plant flows plus the MWD contract amount from Resolution 2014-12-1. Single and multiple dry years is FY 2015/16.

As described in the sections that follow, Table 7-4 through Table 7-6 present the supplies and demands under the various water year scenarios for the 25-year planning period in 5-year increments for combined potable (imported) and non-potable (recycled) water sources.

7.3.1 Normal Water Year

The normal water year is a year in the historical sequence that most closely represents median runoff levels and patterns. Table 7-4 shows the expected imported and recycled water supplies available over the planning period during an average/normal year and compares them to demands for the same period. The expected imported water supply is equivalent to IEUA's purchase order agreement amount with MWD. The expected recycled water supply is based on wastewater plant flow projections from Table 4-6.

The numbers in Table 7-4 demonstrate that the IEUA region anticipates adequate supplies for 2025 to 2045 under normal water conditions.

7.3.2 Single-Dry Year

The water supplies and demands for the IEUA service area over the 25-year planning period were analyzed in the event that a single-dry year occurs. FY 15/16 was selected as a representative single dry year since it was one of the last years of the historic 2011-2017 drought and was hydrologically dry year with low wastewater plant flows that still reflects current recycled water supply and demand trends. Table 7-5 shows the IEUA supply available to meet demands during a single-dry year based on its contract with MWD and 100% of the recycled water projections available during a normal year. As noted above, the imported supply is not expected to decrease during a 5-year drought. The recycled water supplies are based on the percentage of average influent water flows available during FY15/16. The 2015 IRP found that demand during a single dry year is expected to increase by up to 3.74% more than normal year demands by 2040. To account for this increase in demand, a demand increase factor was applied to each 5-year period, ramping up from a 0.62% increase in 2025 to a 3.74% increase in 2040. The 3.74% increase was also applied to calculate the increased demand for 2045.

Despite the demand increase, Table 7-5 still shows a surplus for each 5-year period under single-dry year conditions.

7.3.3 Multiple-Dry Year (5-Year)

The water supplies and demands for the IEUA service area over the 25-year planning period were analyzed in the event that a multiple-dry year occurs, specifically a 5-year drought period. This drought is considered to be equivalent to 5 years of conditions similar to FY 15/16. Table 7-6 shows the supply available to meet demands during a multiple-dry year. As noted above, the imported supply is not expected to decrease during a 5-year drought. The recycled water supplies are based on the percentage of average influent water flows available during FY 15/16. However, the 2015 IRP found that demand during a prolonged drought year is expected to increase by up to 5.98% more than normal year demands by 2040. To account for this increase in demand, a demand increase factor was applied to each 5-year period, ramping up from a 1% increase in 2025 to a 5.98% increase in 2040. This 5.98% increase was also used to calculate the increased demand for 2045.

Despite the demand increase, Table 7-6 still shows a surplus for each 5-year period for each year of the 5-year drought conditions.

Table 7-4: IEUA Service Area: Normal Year Supply and Demand Comparison – in Acre-Feet (DWR Table 7-2)

	2025	2030	2035	2040	2045
Supply totals	153,356	156,490	157,425	160,119	160,119
Demand totals	116,716	120,927	124,136	128,212	128,756
Difference	**36,640**	**35,563**	**33,289**	**31,907**	**31,363**

Note: Normal year based on the average of FY 2015/16- FY 2019/20 conditions.

Table 7-5: IEUA Service Area: Single Dry Year Supply and Demand Comparison - in Acre-Feet (DWR Table 7-3)

	2025	2030	2035	2040	2045
Supply totals	153,329	156,462	157,397	160,091	160,091
Demand totals	118,899	123,938	128,009	133,007	133,571
Difference	**34,431**	**32,524**	**29,388**	**27,084**	**26,519**

Note: IEUA considers FY 15/16 to represent the single dry year hydrologic conditions. The expected supply is 100% of normal year supply. The IEUA IRP forecasts a regional demand increase of 3.74% by 2040 for a single dry year due to above normal temperature and reduced wet periods (IEUA IRP Appendix E, 2016). Demand increase for prior years is interpolated (from 0.62% in 2015 to 3.74% in 2040). The demand increases for 2045 is assumed to be the same as 2040.

Table 7-6: IEUA Service Area: Multiple Dry Years Supply and Demand Comparison – in Acre-Feet (DWR Table 7-4)

Dry Years	Supply	2025	2030	2035	2040	2045
First year	Supply totals	153,329	156,462	157,397	160,091	160,091
	Demand totals	120,206	125,752	130,318	135,879	136,456
	Difference	**33,124**	**30,710**	**27,079**	**24,212**	**23,635**
Second year	Supply totals	153,329	156,462	157,397	160,091	160,091
	Demand totals	120,206	125,752	130,318	135,879	136,456
	Difference	**33,124**	**30,710**	**27,079**	**24,212**	**23,635**
Third year	Supply totals	153,329	156,462	157,397	160,091	160,091
	Demand totals	120,206	125,752	130,318	135,879	136,456
	Difference	**33,124**	**30,710**	**27,079**	**24,212**	**23,635**
Fourth year	Supply totals	153,329	156,462	157,397	160,091	160,091
	Demand totals	120,206	125,752	130,318	135,879	136,456
	Difference	**33,124**	**30,710**	**27,079**	**24,212**	**23,635**
Fifth year	Supply totals	153,329	156,462	157,397	160,091	160,091
	Demand totals	120,206	125,752	130,318	135,879	136,456
	Difference	**33,124**	**30,710**	**27,079**	**24,212**	**23,635**

Note: IEUA considers FY 15/16 to represent each year of the multiple dry year hydrologic conditions. The expected supply is 100% of normal year supply. The IEUA IRP forecasts a regional demand increase of 5.98% by 2040 for a multi-dry year due to above normal temperature and reduced wet periods (IEUA IRP Appendix E, 2016). Demand increase for prior years is interpolated (from 1.00% in 2015 to 5.98% in 2040). The demand increases for 2045 is assumed to be the same as 2040. The supply and demand for each year of the multi-year drought is expected to be the same.

7.4 Summary of Comparisons

As shown in the analyses above, IEUA has adequate supplies to meet demands during normal, single-dry, and multiple-dry years throughout the 25-year planning period. Based on the reliability analysis completed by MWD for their 2020 UWMP, no decrease in imported water from MWD is expected during dry years due to MWD's extensive storage, transfer, and water supply management efforts. Recycled water supplies are also not expected to decrease overall during drought periods since wastewater flows are typically not significantly affected by drought periods. While IEUA does not expect a shortfall under the scenarios considered, they continue to support reduction in water use through demand management measures, as described in Section 8, and consideration of other supply opportunities to increase the resiliency of their water supply. IEUA is also aware of the potential disruption of supply due to water quality changes and is considering future actions that will help to mitigate any impacts, as discussed in Section 6.

7.5 Drought Risk Assessment

The California Legislature created the new Drought Risk Assessment (DRA) requirement for the 2020 UWMP in part because of the significant duration of recent California droughts and the predictions about hydrological variability attributable to climate change. The DRA requires suppliers to assess water supply reliability over a 5-year period from 2021 to 2025 that examines water supplies, water uses, and the resulting water supply reliability under a reasonable prediction for 5 consecutive dry years. Table 7-7 shows the expected water use (in AF) and the expected total supplies for each year from 2021 to 2025 for both potable water from MWD and IEUA recycled water. As with the reliability assessment, the water supplies and demands only include imported water from MWD and recycled water. The water use for each year was found by interpolating between the 2020 actual water demand total (from the FY 19/20 Annual Water Use Report and the FY 19/20 Recycled Water Annual Report) and the 2025 projected water use during a multiple-year drought (from Table 7-6 above). The expected total supplies were calculated by interpolating between the average year supply estimate from Table 7-1 and the 2025 projected supply available during a multiple year drought (from Table 7-6 above).

As shown in Table 7-7, IEUA expects to have a surplus for each of the 5 years of the consecutive 5-year drought. Therefore, no Water Shortage Contingency Plan actions are required to be implemented. However, in the case of a shortfall in supply, the use reduction and supply augmentation measures described in the WSCP (see Appendix B) are available to be implemented. In addition, IEUA is aware of future impacts to their water supplies and is always considering additional potential opportunities for water supplies or use reduction. IEUA may explore the future water supply projects and programs described in Section 4-4 to further increase their resiliency to drought conditions.

Table 7-7: DWR Five-Year Drought Risk Assessment Tables to address Water Code Section 10635(b) (DWR Table 7-5)

2021	Total

2025	**Total**
Total Water Use (AF)	120,206
Total Supplies (AF)	153,329
Surplus/Shortfall w/o WSCP Action (AF)	33,124
Planned WSCP Actions (use reduction and supply augmentation)	
WSCP - supply augmentation benefit (AF)	0
WSCP - use reduction savings benefit (AF)	0
Revised Surplus/(shortfall) (AF)	**33,124**
Resulting % Use Reduction from WSCP action	0%

Note: Years 2021 through 2024 are interpolated between the 2020 actual supply and use values and the 2025 projected supply and use for multi-year drought (from Table 7-4). 2020 actual supply is the average year supply from Table 7-1.

7.6 Description of Management Tools and Options

While IEUA does not anticipate any shortfall during drought periods, they are committed to supporting the water reliability of the region overall. Some of the management tools and options available to IEUA for increasing their regional water supply and reducing water demand have been described within other sections of this document. These tools and options include prioritizing maximizing the use of local water resources and minimizing the need for imported water due to the vulnerability of MWD imported water to climate change impacts such as changing precipitation patterns. IEUA also has a robust water use efficiency program detailed in Section 8 that identifies the most effective water use efficiency measures and partnerships for implementation in the region. This program coupled with savings from codes and standards and increased conservation-related messaging during drought periods can be a strong tool for reducing water use. IEUA has also made increasing the use of their recycled water a priority for future planning efforts, which will increase this source of supply for the region. Additional tools available to the region include water agency interconnections, service line capital improvements by MWD, and mutual aid agreements with other local agencies. Finally, enhanced groundwater management efforts and improvements in regional water management and coordination are also important for maintaining and enhancing the long-term overall resiliency of the region.

Section 8: Demand Management Measures

The purpose of the Demand Management Measures (DMMs) section of this UWMP is to (a) provide a description of the past water conservation programs that IEUA has implemented since 2015 to support its retail agencies in meeting their urban water use reduction targets and (b) describe the activities and actions IEUA may implement in the future.

8.1 Demand Management

For the purposes of this UWMP, DMMs are categorized as "Foundational" and "Other" DMMs. Listed below are those DMMs that the UWMP Act and Water Code specifically mention for wholesalers:

a) Metering
b) Public education and outreach
c) Water conservation program coordination and staffing support.

Activities in addition to the Foundational DMMs that encourage lower water use in the Agency's service area fall in the "Other DMM" category.

In addition, wholesalers must include a narrative description of its distribution system asset management and wholesale supplier assistance programs. In IEUA's case, the majority of its "Other DMMs" are included in the wholesale supplier assistance programs section (Section 8.7), which has been broken into the following categories: residential; CII; and landscape.

8.1.1 Legislative and Regulatory Requirements

As can be expected in a state with ongoing water resource challenges, California's governing entities have issued a number of regulatory requirements and policies over the past decade. Some of the regulations focus on manufacturing standards while others aim to achieve higher levels of water conservation.

State water use efficiency standards are included in SB X7-7, which requires 20% per capita water use reduction by 2020, and Assembly Bill 1881, the Model Water Efficiency Landscape Ordinance (MWELO). The Indoor efficiency standard is set at 55 gallons per person per day and the outdoor efficiency standard is set at 80% of the local evapotranspiration for existing landscapes (2015 WUEBP).

In 2018, the California State Legislature enacted AB 1668 and SB 606 to establish a new foundation for long-term improvements in water conservation and drought planning to adapt to climate change and the resulting longer and more intense droughts in California. The two bills were developed based on Governor Brown's "Making Water Conservation a California Way of Life" Executive Order B-37-16 signed in May 2016, which sets forth actions to use water wisely, eliminate water waste, strengthen local drought resilience, and improve agricultural water use efficiency and drought planning. The two bills provide requirements that affect water use efficiency and drought planning for urban water suppliers, agricultural water suppliers, and small water suppliers and rural communities. The bills also require water suppliers to develop a Water Shortage Contingency Plan and conduct 5-year Drought Risk Assessment every 5 years. IEUA's WSCP and Drought Risk Assessment are included in this UWMP (Appendix B and Section 7.5, respectively).

There are other relevant standards and regulations that establish water use requirements for water agencies and customers that are included in Table 2-8 in Section 2. IEUA's water use efficiency programs and planning efforts comply with all current state legislative and regulatory requirements and increase the resiliency and sustainability of the region's water supplies. IEUA plans to continue its demand management measures to meet any potential future WUE legislation and regulations.

8.1.2 COVID-19 Considerations for FY 19/20

As noted throughout the following sub-sections, the COVID-19 pandemic that began towards the end of FY 19/20 affected IEUA and its retail agencies' delivery and participation of in-person programs. Staff at the retail agencies and IEUA rethought delivery of each program to keep customers, staff, and contractors safe. Programs were adapted to be contactless or virtual where possible. It is a testament to the resiliency and creativity of IEUA's retail agencies and contractors that the programs were adapted and continued with minimal downtime. Despite the pandemic, activity actually increased year-over-year.

While the future remains uncertain, most agree that the impacts of COVID-19 will be felt for some time. As IEUA and its retail agencies look toward the implementation of WUE programs in this new environment, they remain committed to ensuring the health and safety of its personnel, contractors, and customers. The WUE programs will look to leverage this new normal and come up with fresh ideas for the implementation of traditional programs. Among the accommodations and new practices, IEUA foresees a continued shift towards virtual or video-based workshops and services, a greater emphasis of bill savings in promotional materials, and evaluation of alternative program formats such as online stores and direct delivery of free and discounted products.

8.2 Commitment to Water Use Efficiency

Over the last 5 years, the State of California, specifically the southern California region, has reached a critical point in water supply reliability with the convergence of several key factors that include unseasonably low rainfall, critically dry conditions, drought, economic recession, and significant population increases. As a result of these conditions, water use efficiency has become a statewide priority, and most State and local leaders recognize it as a vital component in meeting current and future water supply needs and reliability.

IEUA and retail agencies have recognized the need for developing programs that protect existing water resources so that adequate water supplies will be available for sustainability and future growth. The development of reliable local resources has been critical to maintaining current and future water supplies. In September 1991, IEUA became one of the first water agencies to sign the CUWCC's Memorandum of Understanding Regarding Urban Water Conservation (MOU), accepting and supporting to implement a prescribed set of urban water conservation BMPs. CUWCC is now known as the California Water Efficiency Partnership.

As the regional wholesale supplier of imported water for the area, IEUA has assumed the role of coordinating the region's activities and programs to reduce demand. IEUA has worked closely with IEUA's retail agencies to facilitate the installation of thousands of water saving technologies and devices, as well as the implementation of public outreach and education programs throughout the region. IEUA retail agencies, whose direct contact with retail customers is crucial to the implementation of water use efficiency measures, have co-funded these efforts with IEUA and taken a proactive approach in educating and working with their customers to conserve water.

In light of these circumstances, IEUA and its retail agencies' commitment to conservation has increased over the past 25 years as demonstrated through financial investments, policies, authorization of a broad range of WUE and conservation programs, expansion of the regional recycled water program, support for legislation, and local ordinance implementation. Moving forward, IEUA will continue to implement active and code-based BMP-related activities using strategies identified in the 2020 Regional WUEBP that is currently in development (discussed in the next section).

The future still presents uncertainties and significant challenges in maintaining regional water supply reliability, especially as the impacts of climate change begin to exacerbate the already existing challenges. The continued development of new and expanded local resources is vital to sustaining current and future water sources. Conservation and the efficient use of water is the most cost-effective source of water supply and essential to meeting the regions demand, today and for years to come.

8.3 Water Use Efficiency Business Plan

Over the past 28 years, IEUA and its regional partners have made great progress to attain environmental stewardship and sustainability through the development of local water supplies and reduced dependence on costly and increasingly unreliable imported water. A large part of that progress has come through the implementation of WUE programs and measures. WUE is universally regarded as the most cost-effective method to reduce water demand within a region. WUE encompasses a wide range of programs, services, devices, and innovations that IEUA captures in its Regional WUEBP, which is updated every 5 years. The most recent WUEBP is currently in development in collaboration with IEUA's regional partners. In general, the elements in the WUEBP may focus on using water more efficiently, eliminating water waste, and drought proofing the region through increased use of recycled water, groundwater, stormwater, and other local water supplies.

The WUEBP may focus on identifying target customers that are the most inefficient water users, educating them about WUE attainment, and providing a "road map" to accomplish this. To create the WUEBP, a thorough review of current, past, and potential new programs is being conducted, with calculations to be performed for costs, savings, and overall benefits to the region. The WUEBP may also evaluate developing WUE trends, emerging technologies, and potential MWD funding availability or other grants. The WUEBP may provide a portfolio of recommended programs with direct quantifiable and cost-effective water savings. Each retail agency may elect to modify the design of the programs presented in the WUEBP and may choose to participate in all programs or only a select few. IEUA collaborates with each retail agency to continually evaluate and modify the plan to meet the goals and objectives of the region.

Each year, IEUA prepares a comprehensive annual report that captures all the implemented activities from the past fiscal year. The annual report tracks the progress that has been made against the goals and objectives, identified in the WUEBP, and provides the retail agencies with service area specific data. As part of its annual report, IEUA quantifies the water savings by sector and by measure. The lifetime water savings by measure as of FY 19/20 are shown in Table 8-1. Savings from HETs dominate the lifetime water savings by measure table, at 42% of total savings, followed by turf removal and smart controllers.

The WUEBP is a working document and, as such, must be modified and updated as changes occur, and program years roll out. IEUA regularly reviews the plan and adjusts accordingly. Changes and/or reviews of the plan take place: when programs are added, subtracted, or modified; on an annual basis to meet the annual reporting requirements; every 5 years in parallel with UWMP updates; and as the State's framework policies are finalized.

The 2020 WUEBP in development may identify the future suite of water use efficiency programs for implementation and focuses on increased efforts in landscape management and reducing outdoor water use. Programs are designed to positively impact long-term behavior regarding efficient use of water. Those activities may include device rebates for residential and commercial customers, sprinkler system tune-ups, leak detection system rebates, turf replacement incentives, landscape evaluations, and landscape retrofits which incorporate hardware and climate appropriate plant recommendations that are consistent with landscape ordinances. This is combined with the ability to initiate a comprehensive marketing, education, and outreach program which includes the combined efforts of IEUA and its retail agencies. Details on the 2020 WUEBP in development and its possible selected programs are included in Section 8.9 and throughout the rest of Section 8.

Table 8-1: Lifetime Savings by Measure for Past Achieved Conservation

Measure	Lifetime Savings (AF)	Percent of Total Savings
High Efficiency and Ultra Low Flow Toilets (all markets)	47,448	42%
Turf Removal (all markets)	11,938	11%
Smart Controllers (all markets)	11,106	10%
Residential Landscape Retrofits (small & large)	8,554	8%
High Efficiency Sprinkler Nozzles (all markets)	8137	7%
Ultra-Low Volume Urinals	7,123	6%
High Efficiency Clothes Washers (all markets)	6,502	6%
Landscape Evaluations (all markets)	5,309	5%
Fontana USD Retrofits	4,170	4%
Plumbing Control Valves	476	0.4%
Water Brooms	416	0.4%
Pre-rinse Spray Valves	379	0.3%
X-ray Film Processors	304	0.3%

Measure	Lifetime Savings (AF)	Percent of Total Savings
Sprinkler System Tune-ups	284	0.3%
Laminar Flow Restrictors	247	0.2%
Pressure Regulating Valves	178	0.2%
Cooling Tower Controllers	155	0.1%
Leak Detection Devices	83	0.1%
Pool Covers	28	0.0%
Large Rotary Nozzles	22	0.0%
Air-Cooled Ice Machines	18	0.0%
Rain Barrels & Cisterns	13	0.0%
Total	**112,890**	**-**

Note: Water savings are active savings only.

8.3.1 Core Water Use Efficiency Strategies for the Region

There are five key elements to the WUE strategy within the IEUA region:

- **Promote Water Resource Management.** Manage effective WUE programs at a regional level using sound business decision-making practices to develop and implement strategies to meet water use efficiency targets and stretch limited water resources.

- **Develop and Implement Regional Programs.** Take advantage of economies of scale and stretch the limited regional WUE budget by implementing programs on a regional basis. It is recognized that some programs may only be implemented at the individual agency level, such as budget-based tiered rate structures and WUE ordinances.

- **Build IEUA Retail Agency Cooperation.** Foster cooperation, collaboration, and active participation of all IEUA retail agencies for the successful development and implementation of WUE programs. It is recognized that successful development and implementation of regional WUE programs requires retail agency cooperation in obtaining accurate water demand data, by customer class, in a timely manner, and promotion of cost-effective programs to customers.

- **Develop Incentive-Based Programs.** Develop effective incentive programs that encourage participation, provide public benefit, and achieve quantifiable water savings.

- **Public Recognition.** Provide recognition to customers who have implemented measures resulting in extraordinary water use efficiency achievements.

8.4 Foundational DMMs

8.4.1 Metering

IEUA does not have any direct connections to potable customers. All imported water supplied to the area through IEUA is delivered through direct connections owned by MWD.

8.4.2 Public Education and Outreach

Developed over the last 15 years and in cooperation with its local retail agencies, IEUA participates in and offers an array of regional educational outreach activities. These programs help provide support to the local retailers to help them meet their DMM requirements.

The following is a list of programs and activities implemented over the last 5 years that will continue to be foundational elements of IEUA's regional programs:

National Theater for Children (NTC) Program: Delivers a package of live theater, student curriculum, and teacher guides focused on uses of water, the importance of water, ways water gets polluted, and ways to conserve water to elementary schools throughout the region. In FY 19/20, NTC visited 40 elementary schools throughout the IEUA service area and conducted 74 shows.

Shows that Teach: Fun, theatrical-style productions which teach students about water science, the value of water, and the importance of conservation. Over FY19/20, this program conducted 23 performances at 12 schools. Retail agencies have decided to focus efforts on only one school education program moving forward and the Shows that Teach program will be eliminated.

Water Discovery Field Trip Program: Prior to the COVID-19 pandemic, IEUA provided free educational field trips to the Chino Creek wetlands and Educational Park to promote understanding of the value of natural treatment wetlands, the creation of habitat for endangered/sensitive species, and environmental stewardship. Due to the pandemic, IEUA shifted all education programs from in-person to virtual. In April 2020, IEUA launched Owlie's Virtual Adventures, a program featuring virtual tours, a series of At-Home Activities, how-to videos, and more.

Community Outreach: IEUA annually participates in the following community outreach activities in coordination with its retail agencies: San Bernardino County Water Conference, Landscape and Water Conservation Fair, CVWD's Earth Day, Earth Day at the Chino Creek Wetlands and Educational Park, and the Smart Irrigation Month Hose Nozzle Giveaway. IEUA also participates in other community outreach events that vary year to year.

IEUA's Social Media Outreach: IEUA continues to offer updates via Facebook, YouTube, Twitter, Instagram, and two educational blogs. On these social media platforms, IEUA provides up-to-the-minute information on events, news, education programs, drought updates, water-wise tips, park updates, and wildlife facts.

IEUA's Regional "Water is Life" Student Art/Poster Contest: IEUA hosts its annual "Water is Life" student art/poster contests for grades K-12. The theme "Water is Life" is used to help students express their creativity while focusing on the importance of water. IEUA typically receives over 500 entries annually. The top five winners from each category (K-5; 6-8; 9-12) are entered into MWD's regional contest.

Solar Cup Competition: The annual Solar Cup competition is held each year in May at MWD's Lake Skinner reservoir in the Temecula Valley. High school students from surrounding areas designed, built, equipped, and raced solar-powered boats. This competition encourages well-thought-out boat design, high speed, and endurance, which require participants to use an alternative power source in a real-world application. IEUA co-sponsors three local highs school teams annually. The May 2020 competition was transitioned to a virtual competition that consisted of 12 virtual challenges due to the health precautions related to the COVID-19 pandemic.

The Water Education – Water Awareness Committee: Since 1989, the committee promotes the importance of water conservation in southern California through coordination and participation in community outreach projects and providing grant funded opportunities for local educators. Projects include hosting booths at local resource and educational fairs, conducting water education workshops at local schools, offering grant and scholarship opportunities for educators and students, and sponsoring an annual water conservation video contest and broadcast media and digital art contest.

8.4.3 Water Use Efficiency Program Coordination and Staffing Support

IEUA's WUE Program consists of two full time employees and two interns. Consultants are also hired to help with reports and larger initiatives, like the 5-year WUEBP. In addition, IEUA collaborates with CBWCD, MWD, and two vendors for funding and implementation of specific WUE programs.

Currently, IEUA's WUE program budget is approximately $2.7 million annually, $1.6 million of IEUA funding and another $1.1 million of outside funding. These revenues are collected with the support and cooperation of the retail water agencies. IEUA's revenue collection for water use efficiency and conservation comes from a Meter Equivalent Unit charge, which is the number of active water accounts of each meter served by an IEUA retail agency. Over the past 5 years, IEUA has dedicated an average of $1,600,000 annually to Wholesale Assistance Programs, of which $300,000 goes to education and outreach programs. These local funds are augmented with external funding from sources such as MWD, DWR, and the U.S. Bureau of Reclamation, and other inter-agency partnering programs.

The 2020 WUEBP in development may provide annual regional WUE program budgets with line items dedicated to specific WUE activities for the next 5 years. The draft projected annual budget for each year is shown in Table 8-2. This budget is still in development and may be subject to change. The budget amount reflects the financial commitment of IEUA only and are exclusive of MWD or other external financial contributions. The budgets presented do not align exactly with actual costs because the figures are based upon estimated WUE programming activity that vary depending upon program participation rates.

Table 8-2: IEUA Annual Water Use Efficiency Programs Budget

Fiscal Year	Annual Water Savings (AF)
2020/21	$1,600,000
2021/22	$1,600,000
2022/23	$1,600,000
2023/24	$1,600,000

Fiscal Year	Annual Water Savings (AF)
2024/25	$1,600,000
Total	**$8,000,000**

Notes:
Budget includes IEUA regional program costs exclusive of outside funding.
Budget does not include administrative overhead costs.
Budget includes $300,000 per year for education and outreach programs.
Budget subject to change during 2020 WUEBP development.

8.5 Other DMMs

IEUA has also provided the following programs to support its retail agencies water use efficiency over the past 5 years:

Member Agency Administered Program: This program provides funding support for retail agency implemented local water use efficiency projects that demonstrate water savings. Members submit proposals that include a project scope of work, estimated water savings, and cost. Proposed project may not be duplicative of existing regional programs.

Technology Based Software: IEUA sponsored the development of agency-specific dashboards that allowed its retail agencies to locate high water use landscapes, identify over water-use parcels, track agency use against set State WUE objectives, and direct WUE programs to customer specific needs. These data analytics tools allow IEUA's retail agencies to identify customers more accurately with excess water usage and communicate with them on how their usage compares to accepted WUE standards.

Budget-Based Water Rates: This is one of the most cost effective WUE programs since there is no cost to implement. These rate structures allocate each individual account an amount of water that would be required for efficient indoor and outdoor water use, adjusted to real-time actual weather and customer characteristics. Customers are able to compare their individualized water budget with their actual usage and the appropriate economic signal rewards efficient use. With a clear financial incentive, the customer is motivated to maintain efficient use patterns. Over the last 5 years, three of IEUA's retail agencies have adopted budget-based rate structures within their respective service areas.

Additional "other" DMMs implemented by IEUA are described in the Section 8.7, Wholesale Agency Support.

8.6 Asset Management

IEUA does not own or operate a potable water distribution system, and therefore, does not have any potable water asset management programs.

8.7 Wholesale Agency Support

IEUA provides financial assistance to each of the local retail agencies in an effort to support local WUE implementation efforts. Each retail agency is eligible to receive an annual grant of

$2,000 to support special events, customer surveying, outreach materials, conservation devices, and vehicle magnets. In addition, IEUA covers dues costs for memberships in the Alliance for Water Efficiency and the California Water Efficiency Partnership on behalf of its retail agencies and conducts annual technical workshops that provide retail agencies with information related to specific water use efficiency initiatives, programs, BMP implementation and compliance with new statutory requirements. This is part of IEUA's commitment to the DMMs (Wholesaler Assistance Programs) which requires a wholesaler to provide financial and/or technical assistance to their local retail agencies to implement DMMs.

IEUA has an annual average WUE budget of approximately $1.6 million that is dedicated to supporting the local retail agencies in implementing WUE and conservation related programs. The following subsections detail residential, CII, landscape, and other programs offered by IEUA and its retail agencies over the last 5 years.

8.7.1 Residential Programs

Between 2015 and 2020, IEUA and its retail agencies continued implementing a variety of WUE and conservation programs and products that have led to significant accomplishments in demand reduction and sustained water savings. These programs have consisted of incentives for homeowners and businesses, landscape efficiency, and educational programs. Most of these programs have been very successful and others were introduced as pilots.

The following is a list of activities and programs that were accomplished by IEUA and its retail agencies from 2015 to 2020. Savings as reported by the WUE annual report for FY 19/20 are also included below. Additional details can be found in the annual report.

MWD SoCalWater$mart.com Residential Rebate Program: IEUA's foundational WUE rebate program for residential customers provides incentives for HETs, washing machines, sprinkler nozzles, weather-based irrigation controllers, and rain barrels. IEUA and its retail agencies dedicate funding specifically for enhancing MWD's base rate rebate amounts to attract greater customer participation. In FY 19/20, this program had an annual water savings of 57 AF for a total lifetime savings of 731 AF. A total of 7,051 devices, from over 1,500 residential and commercial customers, were rebated in FY 19/20. High efficiency sprinkler nozzles and HETs are the largest numbers of devices rebated by residential customers. This program has the lowest cost per AF of water savings.

Turf Replacement Program: As part of the Turf Replacement Program, residential customers within IEUA's service area are eligible for a $3 per square-foot rebate partially funded by MWD. In FY 19/20, approximately 184,286 square feet of residential turf was replaced, for an estimated annual water savings of 24 AF and a total lifetime savings of 243 AF.

Residential Pressure Regulation Program: This program, launched in June 2016, installs PRVs at meters, homes, or at the point-of-connection for irrigation systems to automatically reduce high incoming water pressure from water mains and provide a lower, more functional pressure distribution. PRVs ensure that end-use plumbing fixtures operate at the intended flow rate and reduce the incidence of excessively leaky pipes and fixtures. To date, this program has replaced 1,287 PRVs throughout the IEUA service area with projected savings of 4 AF per year and lifetime savings of 45 AF over the life of the devices. MWD completed a study of the water savings following installation of PRVs, these savings are lower than previously expected; however, IEUA's retail agencies have elected to continue with the program because of its highly valued customer service. The program is now provided on a case-by-case basis for customers experience issues with pressure.

Leak Detection Incentive Program: Recent studies of leak detection programs show a reduction in water use of 8% to 18%, with approximately 70% of customers finding leaks. This program, which was starting as a pilot program at the beginning of FY 19/20, provides a point of purchase discount for the Flume Smart Water System. The Flume app provides real time alerts notifying customers of excessively high volume or long duration water usage. It allows customers to better understand their water usage through user-friendly visuals. Demand for this program was unprecedented and the program is being expanded in FY 20/21. This program has an annual savings of approximately 8 AF per year and a lifetime savings of 83 AF.

IEUA Regional Residential Landscape Retrofit Program – DWR/MWD: Initially launched in April 2011, this program provides outdoor irrigation evaluations and retrofits of high efficiency landscape devices for residential water service customers with lot sizes of ¼ acre or larger. Since program inception, a total of 1,672 site retrofits were completed with annual water savings from device upgrades amounting to 932 AF per year and a lifetime savings of 7,962 AF.

IEUA Residential Education, Survey, and Controller Upgrade Program: Focused on the higher water use demographic within the small residential landscape sector, this program promotes an improved understanding of landscape irrigation control technologies while ensuring more efficient scheduling and operation of automated irrigation systems through required training class attendance, landscape evaluations, and smart controller technology upgrades. In FY 19/20, over 450 smart controllers were installed. Program water savings to date is approximately 20 AF per year for an average lifetime savings of 196 AF.

Santa Ana River Conservation and Conjunctive Use Program Smartscape Residential Tune-Up Program: This pilot program was starting in April 2019 to provide services to maximize the efficiency of a customer's existing irrigation system. In partnership with ConservInc., Orange County Coastkeeper, and Inland Empire Water Keeper, the program includes services such as sprinkler repairs, valve replacements, drip irrigation couplers and emitter replacements, minor lateral irrigation line repairs, and a general audit. Final water savings from the program are still being determined.

FreeSprinklerNozzles.com Voucher Program: Launched in April 2011, this program enabled residential and commercial customers within IEUA's service area to obtain a voucher for free high efficiency irrigation spray nozzles through a web-based portal. Since program inception, a total of 2,214 vouchers have been redeemed by residents for a total of 60,591 nozzles and an estimated water savings of 267 AF per year with a lifetime savings of 1,333 AF.

Water Softener Rebate Program: IEUA incentivizes customers through a rebate to remove residential self-regenerating water softeners. Over the course of the program, 901 water softeners have been removed, for water savings of approximate 17 AF per year in addition to the removal of more than 200 tons of salt.

8.7.2 Commercial, Industrial, Institutional Programs

IEUA's service area hosts a diverse range of CII activities, including numerous service industries (such as hotels and restaurants), manufacturing, agriculture and health care, and a large number of schools and colleges. Each of these sectors present unique opportunities to reduce water consumption. Although commercial accounts comprise only 5% of the total number accounts in the IEUA area, they use approximately 17% of overall demand.

The following is a list of activities and programs that were accomplished by IEUA and its retail agencies from 2015 to 2020:

MWD SoCalWater$mart.com CII Rebate Program: IEUA's foundational water use efficiency rebate program for CII customers provides incentives that include plumbing fixtures, landscaping devices, and some industry specific technologies. IEUA and its retail agencies dedicate funding specifically for enhancing MWD's base rate rebate amounts to attract greater customer participation. In FY 19/20, this program had an annual water savings of 93 AF for a total lifetime savings of 1,043 AF. Laminar flow restrictors and HETs are the largest numbers of devices rebated by commercial customers. This program has the lowest cost per AF of water savings.

Turf Replacement Program: As part of the Turf Replacement Program, commercial customers within IEUA's service area are eligible for a $3 per square-foot rebate, partially funded by MWD. In FY 19/20, approximately 318,778 square feet of commercial turf was replaced, for an estimated annual water savings of 42 AF and a total lifetime savings of 421 AF.

Garden in Every School Program: Each year, the Garden in Every School Program awards either a $4,500 grant per school for up to four schools for the establishment of a new water-wise garden or a $1,000 mini-grant to participating schools to support the sustainability of existing gardens. Due to the COVID-19 pandemic, the program was put on hold through FY 20/21.

8.7.3 Landscape Programs

The semi-arid climate of the IEUA service area, with only 15 inches of average rainfall, combined with the lush landscaping aesthetic that is popular in the region, creates a significant water demand for irrigation of outdoor landscaping. The IEUA service area reflects this demand, where outdoor water use is estimated to be nearly 60% of total demand across all sectors. Many of the residential programs detailed in Section 8.7.1 are landscape programs that are categorized as residential programs.

IEUA and its retail agencies have also completed the following list of activities and programs over the last 5 years:

Sprinkler Tune-Up Program: Begun as a pilot in FY 18/19, the program was operated during FY 19/20 by Conserv Inc, IEUA's existing vendor for smart controller installation programs. There was unprecedented customer demand for this program, with a 275% increase in activity year-over-year. The program provides customers with a free landscape irrigation tune-up that includes recommendations for repairs and upgrades, replacement or adjustment of sprinkler heads and nozzles, reparation of valves and bad wiring, controller programming and scheduling, and minor lateral irrigation line repairs. In FY 19/20, 450 tune-up services were performed, and the program achieved an annual water savings of 104 AF for a total lifetime savings of 209 AF.

IEUA/Chino Basin Water Conservation District Landscape Evaluation and Audit Program (LEAP): The LEAP program provides landscape and irrigation evaluations for residential and CII customers. This program was launched in 2007 through a grant from DWR and is available region-wide annually. In FY 19/20, 91 residential and 53 commercial properties were evaluated. The program has an annual savings of 43 AF and a total lifetime savings of 213 AF, the majority of which comes from commercial customers.

IEUA Regional Landscape Training Workshops: In a series of IEUA-sponsored courses, customers learn the latest ways to create sustainable landscape and improve landscape efficiency to reduce outdoor water usage through workshops. The courses cover information on landscape design and preparation, water wise landscaping, mulching, and composting, and more. Only four in-person workshops were held in FY 19/20, in part due to COVID-19 health precautions but also because of decline in customer demand.

Residential Landscape Transformation Program: From October 2012 to June 2016, this program offered residential participants contractor services that included landscape design, selection of climate appropriate plants, removal of living turf, installation of weed barriers and plants, and conversion of overhead sprinklers to drip irrigation. A total of 263 sites were completed removing 232,655 square feet of turf, resulting in an estimated water savings of 34 AF and a lifetime savings of 341 AF.

Landscape Design Assistance Program: This program delivers a comprehensive landscape design package to support front and backyard renovations at no cost to participants. The service has a market value of approximately $500. A partnership between IEUA, the CBWCD, and IEUA's retail agencies, this program is designed to provide participants with a clear and inspiring design that is easily usable by residents who have no experience reading landscape plans. Since the program launch in February 2018, 32 residential landscape designs have been created, eight turf replacement projects were completed, and 19 projects are in progress.

Residential Landscape Guidebook: The step-by-step instruction book includes "how-to's" on resilient landscape design, building healthy soils, selecting climate appropriate plants, and installing efficient irrigation systems. The Guidebook is located online at www.ieua.org/usewaterwisely/landscaping.

Water Saving Garden Friendly: This program helps customers find the resources they need to be water efficient in their landscape. The program developed a micro-website called "Water Saving Garden friendly in the Inland Empire", an online plant database climate specific to the region. The website also includes garden tours, a garden gallery, a search engine for plants, problem solving plant lists, plant and garden information report printouts, a garden resources section, and water conservation tips. The micro-site can be found at www.watersavinggardenfriendly.com.

8.8 Demand Management Achievements (2015-2020)

The above sections detailed recent savings for each program. Majority of these values come from the Alliance for Water Efficiency (AWE) Conservation Tracking Tool, which IEUA uses to plan for and track water conservation program activity and results. The tool helps estimate the effects of plumbing/appliance standards and planned conservation programs on future water use, utility costs and sales revenue, and average customer rates and bills. Data from the region's locally administered programs as well as MWD's regional rebate programs has been collected and entered into the AWE tracking tool for every year back to 1995.

Using the AWE Tracking Tool, for calendar year 2020, IEUA's annual water savings was approximately 408 AF and 3,292 AF over the life of the measures (excludes national plumbing standards). The majority of the annual water savings come from single-family and commercial programs, which are 49% and 44% of annual water savings, respectively. Table 8-3 shows the FY 19/20 lifetime savings by sector, the year's conservation savings through the lifespan of each measure, which varies measure by measure. Again, the single-family sector accounts for the majority of the water savings, at 64%, which comes predominantly through landscape measures, followed by 29% from the commercial sector. Due to the categorization of the programs, there are no annual water savings for the multi-family sector.

Table 8-3: Water Savings by Sector

Sector	Lifetime Water Savings (AF)	Percent of Total Water Savings
Single-Family	13,954	64%
Multi-Family	0	0%
Commercial	6,372	29%
Irrigation	1,515	7%
Total	**21,841**	

The eight major IEUA WUE programs with verifiable water savings are:

- SoCal WaterSmart Rebates (accounts for 37% of FY 19/20 annual savings and 54% of the lifetime savings)
- Sprinkler Tune-Ups (accounts for 25% of FY 19/20 annual savings and 6% of the lifetime savings)
- Turf Replacement (accounts for 16% of FY 19/20 annual savings and 20% of the lifetime savings)
- Landscape Audit and Evaluations (accounts for 11% of FY 19/20 annual savings and 7% of the lifetime savings)
- Smart Controller Upgrades
- Large Landscape Retrofits

- Leak Detection Incentives
- Pressure Regulation.

The quantifiable savings by program that have been achieved over the last 5 years are included in Table 8-4. As shown in these tables, HETs and turf removal have achieved the most savings both over the last 5 years and over all time (as shown previously in Table 8-1), followed by smart controllers and residential landscape retrofits. It should be noted that the HET program was phased out in FY 2015/16 but still are most of the lifetime savings.

Table 8-4: Savings by Program (FY 2015/16 – FY 2019/20)

Measure	Lifetime Savings (AF)	Percent of Total Savings
High Efficiency Toilets (all markets)	10,775	35%
Turf Removal (all markets)	9,027	29%
Residential Landscape Retrofits (small & large)	4,450	14%
Smart Controllers (all markets)	2,025	7%
High Efficiency Sprinkler Nozzles (all markets)	1872	6%
High Efficiency Clothes Washers (all markets)	890	3%
Landscape Evaluations (all markets)	704	2%
Plumbing Control Valves	476	2%
Sprinkler System Tune-ups	284	1%
Pressure Regulating Valves	178	1%
Laminar Flow Restrictors	142	0.5%
Leak Detection Devices	83	0.3%
Ultra-Low Volume Urinals	29	0.1%
Air-Cooled Ice Machines	14	0.0%
Cooling Tower Controllers	13	0.0%
Rain Barrels & Cisterns	12	0.0%
Total	**30,974**	-

8.9 2020 WUEBP and Future Demand Management Measures

IEUA recognizes that conserving water and increasing water use efficiency is an integral component of a responsible water management strategy. The IEUA region has achieved its 2020 SBX7-7 water use target largely by focusing on offering customers a portfolio of programs to increase indoor and outdoor water efficiency measures, developing building codes and landscape ordinances, and reducing demand for potable water by increasing recycled water supply. IEUA is committed to providing its customers with the education and tools to maintain and even lower their current water use.

The most recent WUEBP is currently in development and will be completed in 2021. The document may be split into two phases. The first phase may cover the WUE plans for the next 2 years. The second phase may be released as an addendum to the WUEBP and will cover the subsequent 3 years of the 5-year planning period. This potential breakdown into two phases would allow IEUA and its regional partners to collaborate more effectively and give more time to dive into its plans to meet upcoming water use regulations. In general, the elements in the WUEBP may focus on using water more efficiently, eliminating water waste, and drought proofing the region through increased use of recycled water, groundwater, stormwater, and other local water supplies. As of the time of this writing, the 2020 WUEBP is still in development; any information included in Section 8 related to the 2020 WUEBP is therefore, subject to change.

As part of the development of the 2020 WUEBP, a possible a portfolio of recommended programs and new technologies have been identified for implementation over the next 5 years that will help the region achieve a prolonged, increased level of water efficiency. While the IEUA regional alliance is currently exceeding water use targets set by SBX7-7, IEUA will continue to implement the DMMs to further lower water uses in anticipation of future water use objectives. The programs, policies, and technologies detailed in the WUEBP will assist in helping IEUA's retail agencies to maintain the conservation levels to allow them to stay in compliance with the SBX7-7 2020 target as described in Section 3 of this UWMP.

Along with continuing its education and outreach programs, the development of the 2020 WUEBP identified possible selected programs for implementation as shown in Table 8-5 below. The table also includes a summary of the reasoning behind the potential selection and the support actions required for each program. These selected programs are subject to change with the further development of the 2020 WUEBP.

Table 8-5: Selected Programs and Reasoning

Program	Reasoning	Support Actions
Landscape Evaluations	• Links customer with WUE Programs • Provides one-on-one customer education • Starts relationship with customer	• Prioritize large landscape customers – if possible, customers that are above their water budget allocation • Provide more in-depth cost/benefit information • Provide personalized follow-up and support
Sprinkler System Tune-Up	• Nearly all irrigation systems need repairs • Repairs are necessary before efficiency upgrades are made otherwise new products will not work as designed • There are millions of sprinkler nozzles in the IEUA territory that are not high efficiency and need to be retrofitted • Measures are professionally installed by qualified contractors	• Nearly all irrigation systems need repairs • Repairs are necessary before efficiency upgrades are made otherwise new products will not work as designed • There are millions of sprinkler nozzles in the IEUA territory that are not high efficiency and need to be retrofitted • Measures are professionally installed by qualified contractors
Large Landscape Retrofit	• Targets large water use • Site visit verifies there will be savings • Professional installations and programming of controller	• Identify customers through Tune-up Program • Additionally, market locally • Provide electronic follow-up with customer to ensure sustained savings

Program	Reasoning	Support Actions
Small Smart Controller Upgrade	• Offering to smaller lots provides bigger pool of potential customers • Site visits verifies there will be savings • Educational workshop ensures customer can program and maintain controller and therefore, sustain savings	• Use water budget and potential savings to show return on investment • Consider providing video conferencing for controller programming assistance • Consider customer co-pay to lower costs
Turf Replacement Incentive	• There are hundreds of thousands of square feet of irrigated turf in IEUA territory • Replacing turf with regionally appropriate plants aids in transforming the market • Program provides long term savings	• Provide easier access to support services • Link customers with design services • Follow up with customers to assist them through process
SoCal Water Smart Rebates	• MWD funding • MWD administration • Most cost-effective program • Ease of implementation	• Continue to add incentive dollars to priority measures • Promote through all other programs • Market locally
Leak Detection Incentive	• Many homes have leaks, currently industry estimates 10% • Most leaks go undetected and customers are not aware for months until they get their bill • Repairing water damage caused by leaks can cost thousands of dollars for a typical homeowner • Providing customers with data on their water use gives them the necessary information and motivation to make efficiency changes	• Finalize program delivery – standard rebate vs home delivery • Market locally
Low Income Leak Repair	• Addresses equity and affordability issues – especially increasing financial impacts of COVID-19 • Repairing water damage caused by leaks can cost thousands of dollars for a typical homeowner • Financially vulnerable population cannot afford to fix leaks • Customers value service and builds relationship with water agency • Program provides excellent PR	• Consider partnering with housing agencies or energy utility • Conduct outreach to targeted population • Identify leaks through water use analysis and preemptively reach out to customers
Pressure Regulating Valve Installations	• Many home plumbing systems have leaks and operate above the intended flow rate due to high pressure	• Consider customer co-pay option to lower costs • Target customers with complaints about high water pressure • Use as a means for promoting other conservation measures

Note: Information from Draft 2020 WUEBP, information subject to change.

The draft 2020 WUEBP currently estimates that its water conservation programs will save approximately 9,008 AF of water over the next 5 years, at a cost of $52/AF. This cost falls well below the region's cost of purchasing imported water from MWD, which is $1,122/AF. Table 8-6 shows the potential projected annual water savings to be achieved through the 5-year plan currently being outlined in the 2020 WUEBP. These plans are subject to change with further development of the 2020 WUEBP.

Table 8-6: Projected Annual Water Savings

Fiscal Year	Annual Water Savings (AF)
2020/21	691
2021/22	1,340
2022/23	1,851
2023/24	2,333
2024/25	2,792
Total	**9,008**

Note: Values from Draft 2020 WUEBP, information is subject to change.

These potential projected annual water savings come from the projected annual activity for each measure, shown in Table 8-7 below.

Table 8-7: Annual Activities by Measure (units vary)

Measure	FY 2020/21	FY 2021/22	FY 2022/23	FY 2023/24	FY 2024/25
SCWS Premium Efficiency Toilet Rebates	550	550	550	550	550

Section 9: Energy Intensity Reporting

9.1 Overview

Water and energy resources are inherently connected. The California Energy Commission estimates that the transport and treatment of water, treatment and disposal of wastewater, and the energy used to heat and consume water account for nearly 20% of the total electricity and 30% of non-power plant related natural gas consumed in California. In 2015, California issued new rules requiring 50% of its power to come from renewables, along with a reduction in greenhouse gas emissions to 40% below 1990 levels by 2030. In 2018, Governor Jerry Brown signed Senate Bill 100 (SB100) into law, committing California to 100% carbon-free energy by 2045. IEUA has voluntarily reported the energy intensity of its wastewater and recycled water operations to assist with this goal. IEUA does not own or operate any potable water facilities.

The methodology for calculating water energy intensity outlined in Appendix O of the UWMP Guidebook was adapted from the California Institute for Energy Efficiency exploratory research study titled “Methodology for Analysis of the Energy Intensity of California’s Water Systems” (Wilkinson 2000). The study defines water energy intensity as the total amount of energy, calculated on a whole-system basis, required for the use of a given amount of water in a specific location.

UWMP reporting is limited to energy intensity associated with water management processes occurring within an urban water supplier’s direct operational control. Operational control is defined as authority over normal business operations at the operational level. Any energy embedded in water supplies imparted by an upstream water supplier (e.g., water wholesaler) or consequently by a downstream water purveyor (e.g., retail water provider) is not included in the UWMP energy intensity tables. IEUA’s calculations for wastewater treatment and recycled water conform to methodologies outlined in the UWMP Guidebook and Wilkinson study.

The water supply energy intensity and wastewater and recycled water energy intensities were calculated for the 2019-2020 fiscal year (July 1st through June 30th). The energy use associated with the wastewater and recycled water processes is shown below in Table 9-1. IEUA’s administrative facilities do not have dedicated energy consumption meters and instead share meters with the connected wastewater and recycled water facilities. As such, the per facility energy usage below includes administrative energy use. Excluding imported electricity that may come from renewable sources, approximately 32% of the total energy associated with IEUA’s wastewater and recycled water operations came from renewable sources, specifically solar, wind, and biogas capture.

Table 9-1: Energy Use for FY 19-20 Wastewater and Recycled Water Processes

Facility	Electricity (kWh)	Natural Gas (kWh)	Diesel (kWh)	Propane (kWh)	Biogas (kWh)	Renewables (kWh)
Wastewater Operations (FY 19-20)						
CCWRF	6,093,490	2,491	20,515	3,643	-	291,104
RP-1	19,764,610	137,798	121,964	132,753	19,682,446	1,472,002
RP-2	2,127,332	51,597	67,851	607	7,164,301	-
RP-4	7,040,126	4,922	27,336	2,226	-	311,110
RP-5	8,612,362	2,288,982	23,293	607	-	1,938,054
Biosolids Handling	-	-	875,072	-	-	-

Philadelphia Lift Station	651,913	-	-	-	-	-
San Bernardino Lift Station	492,701	-	-	-	-	-
Prado Dechlorination Station	59,073	-	-	-	-	-
Prado Lift Station	893	-	-	-	-	-
Recycled Water Operations (FY 19-20)						
CCWRF	3,186,402	-	-	-	-	-
RP-1	6,910,814	-	-	-	-	-
RP-2	-	-	-	-	-	-
RP-4	2,614,994	-	-	-	-	-
RP-5	2,518,862	-	-	-	-	-
1630 E. Station	1,108,112	-	-	-	-	-

Notes:
1. Data collected for FY 2019/2020 from metered data.
2. Energy use data includes energy used for administrative buildings.
3. Diesel numbers are based on purchases and are an average of FY18-19 and FY19-20.
4. The Philadelphia Lift Station energy use is not included in the calculation of wastewater energy intensity; the lift station pumps high strength brine to the non-reclaimable wastewater system.

kWh = kilowatt-hour

9.2 Water Supply Energy Intensity

IEUA is a wholesale distributor of imported water and treats and delivers recycled water to retail agencies and some large retail agricultural customers for the purposes of agriculture, municipal irrigation, industrial uses, and groundwater replenishment. Recycled water is not included in the water supply energy intensity calculations but is included in the following section with wastewater. Since IEUA does not own any water supply infrastructure, it does not have any energy use related to its water supply and distribution, resulting in an energy intensity of zero kilowatt-hours per acre-foot. Table 9-2 (DWR’s Table O-1A) is included below with this information in the narrative section.

Table 9-2: Water Supply Energy Intensity

Metered Data

Data Quality Narrative:

Narrative:

IEUA does not use any energy for stormwater management. Any energy associated with imported water is associated with the infrastructure owned and operated by MWD. IEUA therefore has no energy use associated with its water management process. Any energy associated with groundwater recharge is included in the wastewater and recycled water energy intensity calculations. Any upstream embedded energy consumed prior to IEUA taking control of its imported MWD water or downstream embedded energy consumed by IEUA's member agencies to treat or distribute this water is not included in this analysis.

9.3 Wastewater and Recycled Water Energy Intensity

IEUA manages regional sewage service within its 242-square mile service area to collect, treat, and dispose of wastewater delivered by contracting local agencies. A system of regional trunk and interceptor sewers conveys sewage to five regional wastewater treatment plants owned and operated by IEUA. Wastewater facilities use tertiary treatment to produce recycled water meeting Title 22 standards for non-potable reuse and groundwater replenishment. Recycled water that is not reused is discharged to the Santa Ana River. IEUA delineates wastewater from recycled water at the point following chlorination and prior to the recycled water pump stations.

In addition to wastewater and recycled water infrastructure, IEUA also operates the Prado Dechlorination Facility, Inland Empire Regional Composting Facility, and Chino Creek Wetlands & Educational Park. While operationally controlled by IEUA, the Inland Empire Regional Composting Facility and Chino Creek Wetlands & Educational Park are not directly related to the collection, treatment, or distribution of wastewater or recycled water and thus considered outside the reporting boundaries. While the UWMP Guidebook energy intensity definition considers the energy consumed for all Wastewater Management Processes (collect, treat, and discharge wastewater) and energy consumed for all Recycled Water Management Processes (convey, treat, and distribute recycled water supplies) IEUA has also included the energy consumption from administrative buildings, such as IEUA's headquarters facility, in the energy intensity calculation. This is because IEUA administrative facilities are directly connected to and share energy meters with wastewater and recycled water facilities. The energy associated with the NRWS is not included in the energy intensity calculations.

Over FY 19-20, IEUA collected and treated 55,245 AF of wastewater. 30,495 AF of recycled water was produced, of which 17,115 AF was distributed to retail agencies and retail customers and the remaining 13,381 AF was recharged. Any wastewater that was not recycled was discharged to the Santa Ana River; in FY 19-20 this volume was 24,750. Wastewater volume is based on metered data at the recycling plants.

Table 9-3 shows the energy intensity calculated for the wastewater and recycled water operations using the energy use provided in Table 9-1. The volume of wastewater entering the process is the amount of wastewater treated at the regional water recycling plants RP-1, RP-4, RP-5, and CCWRF. The wastewater is tertiary treated to recycled water meeting Title 22 quality standards for non-potable use and groundwater recharge. Of this volume, a portion is dechlorinated and then discharged to the Santa Ana River. There is no energy associated with the collection or conveyance of recycled; this energy is captured within the energy use for the wastewater operations collection and conveyance. The Philadelphia Lift Station conveys non-reclaimable wastewater to Los Angeles County; the volume and energy use associated with this lift station is therefore, not included in the wastewater energy intensity calculations.

A portion of the energy used in the wastewater and recycled water processes comes from self-generated renewable energy. In FY 19-20, the amount of renewable energy used was 30,859,017 kWh, of which 4,012,270 kWh was from renewable energy sources (solar and wind) and 26,846,747 kWh comes from the capture of biogas. A portion of biogas produced during wastewater treatment is captured and beneficially used as part of IEUA's treatment process. Unused biogas is flared to convert methane to carbon dioxide and reduce greenhouse gas emissions from the facilities. All the self-generated renewable energy is used in the wastewater treatment process. Not included in this amount of renewable energy is the portion of purchased electricity that is supplied through sustainable sources. IEUA purchases electricity from Southern California Edison. On average, 30% of the electricity purchased is considered sustainable.

Quantity of Self-Generated Renewable Energy related to recycled water and wastewater operations

34,713,912 kWh

Data Quality *(Estimate, Metered Data, Combination of Estimates and Metered Data)*

Metered Data

Data Quality Narrative:

Volume of water entering process based on metered data. Metering completed at each wastewater treatment plant.

Narrative:

The volume of wastewater entering the process is the amount of wastewater treated at the regional water recycling plants RP-1, RP-4, RP-5, and CCWRF. The wastewater is tertiary treated to recycled water meeting Title 22 quality standards for non-potable use and groundwater recharge. A portion is dechlorinated and then discharged to the Santa Ana River. The Philadelphia lift station pumps brine to the non-reclaimable water system and is therefore not included in the wastewater energy intensity calculations. All other wastewater discharge flows by gravity to the Santa Ana River. There is no energy associated with the collection or conveyance of recycled water since the volume just moves within the regional water recycling plants.

A portion of the energy used in the wastewater and recycled water processes comes from self-generated renewable energy. In FY 19-20, the amount of renewable energy used was 34,713,912 kWh, of which 7,867,165 kWh was from renewable energy sources (solar and wind) and 26,846,747 kWh comes from the capture of biogas. This amount is approximately 32% of IEUA's total energy use. A portion of biogas produced during wastewater treatment is captured and beneficially burned as part of IEUA's treatment process. Unused biogas is flared to convert methane to carbon dioxide and reduce greenhouse gas emissions from the facilities. All the self-generated renewable energy is used in the wastewater treatment process. Not included in this amount of renewable energy is the portion of purchased electricity that is supplied through sustainable sources. IEUA purchases electricity from Shell and Southern California Edison (SCE). On average, 30% of the electricity purchased from Shell and SCE is considered sustainable.

IEUA also operates the Inland Empire Regional Composting Facility and the Chino Creek Wetlands & Education Park. While operationally-controlled by IEUA, these facilities are not directly related to the collecction, treatment, or discharge of wastewater or recycled water and are considered outside the reporting boundaries. Similarly, while much of IEUA's headquarters and vehicles are dedicated to supporting wastewater and recycled water operations, to maintain consistency with the UWMP Guidebook, energy consumption from these operations has been excluded.

9.4 Key Findings

Calculating operational energy intensities helps agencies understand the water-energy nexus as it relates to their operations and processes. However, there is still work that needs to be done to better understand upstream and downstream water-energy impacts. Reporting boundaries are important to consider when comparing energy intensities between providers and water supply sources, since these boundaries exclude any embedded energy impacts on downstream users. Engaging the upstream and downstream supply chain can lead to more informed decisions that benefit the environment and the engaged parties.

IEUA has taken advantage of its renewable resources by developing a diverse energy portfolio, but additional planning is needed to address changing environmental regulations that may dictate available technologies. To continue providing reliable services to the region while remaining a steward of the environment, IEUA completed a CCAP in 2018. This plan outlined four business goals: maximizing local water supplies, maintaining the health of the groundwater aquifer, maximizing system efficiencies, and measuring performance. These goals will not only guide the agency's energy use but will minimize the agency's impact on the environment. Excluding imported electricity from renewable sources, approximately 32% of the total energy associated with IEUA's wastewater and recycled water operations came from renewable sources, specifically solar, wind, and biogas capture.

Section 10: Seismic Risk Assessment

Per the Water Code Section 10632.5, suppliers are required to assess seismic risk to water supplies as part of their WSCP. The plan also must include a seismic risk assessment and mitigation plan to assess the vulnerability of each of the various facilities of a water system and mitigate those vulnerabilities.

Pursuant to Water Code, the seismic risk assessment must include a description of the vulnerability of each of its water system(s) facilities. Suppliers are encouraged to assess the vulnerability of external facilities or components that extend outside the supplier's service distribution area (e.g., transmission pipes, delivery canals, surface water diversion pumps) since failure of them would still ultimately disrupt the supplier's ability to serve their customers.

As a wholesaler, IEUA does not own or operate any potable water supply infrastructure and therefore, did not conduct a seismic risk assessment. IEUA purchases imported water from MWD, which conducted a seismic risk assessment as part of its 2020 UWMP. A brief summary of MWD's Seismic Risk Assessment and Mitigation Plan (Appendix 9 of MWD'S 2020 UWMP) is included here.

MWD has developed a holistic strategy for seismic resiliency that includes providing a diversified water supply portfolio, establishing system flexibility and emergency storage, preventing damage to infrastructure during seismic or other extreme events, and minimizing water delivery interruptions through a dedicated emergency response and recovery organization. MWD's water conveyance and distribution facilities are designed either to withstand a maximum probable seismic event or to minimize the potential repair time in the event of damage. MWD's ongoing program works to evaluate the seismic risk of aboveground structures, dams, and pipelines based on the current state of practice, operating conditions, seismicity criteria, and asset management strategies. Infrastructure will be prioritized for rehabilitation based on the results of these evaluations. MWD also conducts special seismic assessments periodically to increase understanding of the vulnerability of its assets and operations to various seismic hazards. In addition, MWD is working with the State of California on the Delta Risk Management Strategy to reduce impacts of a seismic event in the Delta that would cause levee failure and disruption of SWP deliveries (MWD 2021). Further information on MWD's seismic risk assessment and resiliency plan can be found in MWD's 2020 UWMP, Appendix 9.

IEUA delivers imported water to its retail agencies via MWD's infrastructure. These retail agencies then distribute the imported water via their own collection and distribution system infrastructure. As part of each retail agencies' 2020 UWMP, they have conducted seismic risk assessments to identify any existing vulnerabilities and identify mitigation measures for implementation. Details of these risk assessments can be found within each respective agencies' 2020 UWMP.

IEUA designs, builds, and operates recycled water treatment and distribution system infrastructure. The recycled water infrastructure owned by IEUA is all designed and constructed in compliance with the most recent California Building Code (CCR Title 24, Part 2) and the standards and practices in place in the time of design. The majority of IEUA's recycled water infrastructure was constructed or retrofitted after 1994, when the 6.7 magnitude earthquake in Northridge occurred. This landmark earthquake motivated significant revisions to the California Building Code to include stronger seismic resilience design requirements, which were finalized in 1998. IEUA's first major regional recycled water pipeline was constructed in 1995 and a backbone recycled water distribution system was installed in Chino and Chino Hills from CCWRF in 1997. Some of its water recycling plants were constructed prior to 1994 but have since been updated to comply with the current seismic design standards.

UWMP Checklist

DWR Checklist for 2020 UWMP
Checklist Arranged by Subject

Water Code Section	Summary as Applies to UWMP	Subject	2020 Guidebook Location	2020 UWMP Location (e.g. Section(s), page number(s), table/figure number(s) or briefly describe why CWC section does not apply)
10608.20(e)	Retail suppliers shall provide baseline daily per capita water use, urban water use target, interim urban water use target, and compliance daily per capita water use, along with the bases for determining those estimates, including references to supporting data.	Baselines and Targets	Chapter 5	Section 3; Tables 3-2, 3-3, and 3-4.
10608.22	Retail suppliers' per capita daily water use reduction shall be no less than 5 percent of base daily per capita water use of the 5 year baseline. This does not apply if the suppliers base GPCD is at or below 100.	Baselines and Targets	Section 5.7.2	Section 3; Tables 3-2, 3-3, and 3-4.
10608.24(a)	Retail suppliers shall meet their water use target by December 31, 2020.	Baselines and Targets	Section 5.7	Section 3.1.2; Table 3-4.
10608.24(d)(2)	If the retail supplier adjusts its compliance GPCD using weather normalization, economic adjustment, or extraordinary events, it shall provide the basis for, and data supporting the adjustment.	Baselines and Targets	Sections 5.2 and 5.5.7	Not applicable.
10608.36	Wholesale suppliers shall include an assessment of present and proposed future measures, programs, and policies to help their retail water suppliers achieve targeted water use reductions.	Baselines and Targets	Section 5.1	Section 8.7.
10608.4	Retail suppliers shall report on their progress in meeting their water use targets. The data shall be reported using a standardized form.	Baselines and Targets	Section 5.8 and App E	Section 3.1.2, Tables 3-3 and 3-4. Also Appendix F.
10631(e)(1)	Retail suppliers shall provide a description of the nature and extent of each demand management measure implemented over the past five years.	Demand Management Measures	Sections 9.2 and 9.3	Not applicable.
10631(e)(2)	Wholesale suppliers shall describe specific demand management measures listed in code, their distribution system asset management program, and supplier assistance program.	Demand Management Measures	Sections 9.1 and 9.3	Section 8.4, 8.5, 8.6, 8.7, and 8.8.
10608.26(a)	Retail suppliers shall conduct a public hearing to discuss adoption, implementation, and economic impact of water use targets.	Plan Adoption, Submittal, and Implementation	Chapter 10	Not applicable.
10621(b)	Notify, at least 60 days prior to the public hearing, any city or county within which the supplier provides water that the urban water supplier will be reviewing the plan and considering amendments or changes to the plan.	Plan Adoption, Submittal, and Implementation	Section 10.2.1	Section 1.12; Tables 1-6, 1-7, 1-8. Appendix E.
10621(f)	Each urban water supplier shall update and submit its 2020 plan to the department by July 1, 2021.	Plan Adoption, Submittal, and Implementation	Sections 10.3.1 and 10.4	IEUA will comply with this provision.
10635(c)	Provide supporting documentation that Water Shortage Contingency Plan has been, or will be, provided to any city or county within which it provides water, no later than 60 days after the submission of the plan to DWR.	Plan Adoption, Submittal, and Implementation	Sections 8.12, 10.4	Appendices B and Appendix E.
10642	Provide supporting documentation that the urban water supplier made the plan and contingency plan available for public inspection, published notice of the public hearing, and held a public hearing about the plan and contingency plan.	Plan Adoption, Submittal, and Implementation	Sections 10.2.2, 10.3, and 10.5	Section 1.12; Tables 1-6, 1-7, 1-8. Also Appendices E and B.
10642	The water supplier is to provide the time and place of the hearing to any city or county within which the supplier provides water.	Plan Adoption, Submittal, and Implementation	Section 10.2	Section 1.12; Tables 1-6, 1-7, 1-8. Appendix E.
10642	Provide supporting documentation that the plan and contingency plan has been adopted as prepared or modified.	Plan Adoption, Submittal, and Implementation	Section 10.3.1	Section 1.12; Tables 1-6, 1-7, 1-8. Also Appendix D. [pending]
10644(a)	Provide supporting documentation that the urban water supplier has submitted this UWMP to the California State Library.	Plan Adoption, Submittal, and Implementation	Section 10.5	Section 1.12; Tables 1-6, 1-7, 1-8. Also Appendix D. [pending]
10644(a)(1)	Provide supporting documentation that the urban water supplier has submitted this UWMP to any city or county within which the supplier provides water no later than 30 days after adoption.	Plan Adoption, Submittal, and Implementation	Section 10.5	Section 1.12; Tables 1-6, 1-7, 1-8. Also Appendix D. [pending]
10644(a)(2)	The plan, or amendments to the plan, submitted to the department shall be submitted electronically.	Plan Adoption, Submittal, and Implementation	Sections 10.4.1 and 10.4.2	IEUA will comply with this provision.

DWR Checklist for 2020 UWMP
Checklist Arranged by Subject

Water Code Section	Summary as Applies to UWMP	Subject	2020 Guidebook Location	2020 UWMP Location *(e.g. Section(s), page number(s), table/figure number(s) or briefly describe why CWC section does not apply)*
10645(a)	Provide supporting documentation that, not later than 30 days after filing a copy of its plan with the department, the supplier has or will make the plan available for public review during normal business hours.	Plan Adoption, Submittal, and Implementation	Section 10.5	IEUA will comply with this provision. Section 1.12; Tables 1-6, 1-7, 1-8. Also Appendix D.
10645(b)	Provide supporting documentation that, not later than 30 days after filing a copy of its water shortage contingency plan with the department, the supplier has or will make the plan available for public review during normal business hours.	Plan Adoption, Submittal, and Implementation	Section 10.5	Appendix B.
10620(b)	Every person that becomes an urban water supplier shall adopt an urban water management plan within one year after it has become an urban water supplier.	Plan Preparation	Section 2.1	IEUA complies with this provision.
10620(d)(2)	Coordinate the preparation of its plan with other appropriate agencies in the area, including other water suppliers that share a common source, water management agencies, and relevant public agencies, to the extent practicable.	Plan Preparation	Section 2.5.2	Section 1.12 and 1.13.
10642	Provide supporting documentation that the water supplier has encouraged active involvement of diverse social, cultural, and economic elements of the population within the service area prior to and during the preparation of the plan and contingency plan.	Plan Preparation	Section 2.6	Section 1.12; Tables 1-6, 1-7, 1-8. Also Appendix E.
10630.5	Each plan shall include a simple description of the supplier's plan including water availability, future requirements, a strategy for meeting needs, and other pertinent information.	Summary	Chapter 1	Section 1.
10631(a)	Describe the water supplier service area.	System Description	Section 3.1	Section 1.5.1.
10631(a)	Describe the climate of the service area of the supplier.	System Description	Section 3.3	Section 1.10.
10631(a)	Provide population projections for 2025, 2030, 2035, 2040 and optionally 2045.	System Description	Section 3.4	Section 1.6; Table 1-4.
10631(a)	Describe other social, economic, and demographic factors affecting the supplier's water management planning.	System Description	Section 3.4	Section 1.7.
10631(a)	Describe the land uses within the service area.	System Description	Section 3.5	Section 1.9.
10631(a)	Indicate the current population of the service area.	System Description and Baselines and Targets	Sections 3.4 and 5.4	Section 1.6.
10631(b)	Identify and quantify the existing and planned sources of water available for 2020, 2025, 2030, 2035, 2040 and optionally 2045.	System Supplies	Section 6.2.8	Section 4; Tables 4-3, 4-4, 4-5, 4-6, 4-8.
10631(b)	Indicate whether groundwater is an existing or planned source of water available to the supplier.	System Supplies	Section 6.2	Section 4.2.2; Table 4-3.
10631(b)(1)	Provide a discussion of anticipated supply availability under a normal, single dry year, and a drought lasting five years, as well as more frequent and severe periods of drought.	System Supplies	Section 6.2	Section 7; Tables 7-2, 7-3, 7-4, 7-5, 7-6, 7-7.
10631(b)(2)	When multiple sources of water supply are identified, describe the management of each supply in relationship to other identified supplies.	System Supplies	Section 6.1	Section 4.
10631(b)(3)	Describe measures taken to acquire and develop planned sources of water.	System Supplies	Section 6.1	Section 4.4; Table 4-8.
10631(b)(4)(A)	Indicate whether a groundwater sustainability plan or groundwater management plan has been adopted by the water supplier or if there is any other specific authorization for groundwater management. Include a copy of the plan or authorization.	System Supplies	Section 6.2.2	Section 4.2.2.2.1.

DWR Checklist for 2020 UWMP
Checklist Arranged by Subject

Water Code Section	Summary as Applies to UWMP	Subject	2020 Guidebook Location	2020 UWMP Location *(e.g. Section(s), page number(s), table/figure number(s) or briefly describe why CWC section does not apply)*
10631(b)(4)(B)	Describe the groundwater basin.	System Supplies	Section 6.2.2	Section 4.2.2.
10631(b)(4)(B)	Indicate if the basin has been adjudicated and include a copy of the court order or decree and a description of the amount of water the supplier has the legal right to pump.	System Supplies	Section 6.2.2	Section 4.2.2.2.1.
10631(b)(4)(B)	For unadjudicated basins, indicate whether or not the department has identified the basin as a high or medium priority. Describe efforts by the supplier to coordinate with sustainability or groundwater agencies to achieve sustainable groundwater conditions.	System Supplies	Section 6.2.3	Not applicable.
10631(b)(4)(C)	Provide a detailed description and analysis of the location, amount, and sufficiency of groundwater pumped by the urban water supplier for the past five years	System Supplies	Section 6.2.4	Section 4.2.2.1; Table 4-3.
10631(b)(4)(D)	Provide a detailed description and analysis of the amount and location of groundwater that is projected to be pumped.	System Supplies	Section 6.2	Not applicable, IEUA does not pump groundwater.
10631(c)	Describe the opportunities for exchanges or transfers of water on a short-term or long- term basis.	System Supplies	Section 6.7	Section 4.4.2.
10631(f)	Describe the expected future water supply projects and programs that may be undertaken by the water supplier to address water supply reliability in average, single- dry, and for a period of drought lasting 5 consecutive water years.	System Supplies	Section 6.8	Section 4.4 and 7.6.
10631(g)	Describe desalinated water project opportunities for long-term supply.	System Supplies	Section 6.6	Section 4.4.3.
10631(h)	Retail suppliers will include documentation that they have provided their wholesale supplier(s) - if any - with water use projections from that source.	System Supplies	Section 2.5.1	Not applicable.
10631(h)	Wholesale suppliers will include documentation that they have provided their urban water suppliers with identification and quantification of the existing and planned sources of water available from the wholesale to the urban supplier during various water year types.	System Supplies	Section 2.5.1	Appendix E.
10633(b)	Describe the quantity of treated wastewater that meets recycled water standards, is being discharged, and is otherwise available for use in a recycled water project.	System Supplies (Recycled Water)	Section 6.2	Section 5.3; Table 5-1.
10633(c)	Describe the recycled water currently being used in the supplier's service area.	System Supplies (Recycled Water)	Section 6.2	Section 5.3; Table 5-1.
10633(d)	Describe and quantify the potential uses of recycled water and provide a determination of the technical and economic feasibility of those uses.	System Supplies (Recycled Water)	Section 6.2	Section 5.4 and 5.5; Table 5-2.
10633(e)	Describe the projected use of recycled water within the supplier's service area at the end of 5, 10, 15, and 20 years, and a description of the actual use of recycled water in comparison to uses previously projected.	System Supplies (Recycled Water)	Section 6.2	Section 5.4 and 5.5; Tables 5-2, 5-3.
10633(f)	Describe the actions which may be taken to encourage the use of recycled water and the projected results of these actions in terms of acre-feet of recycled water used per year.	System Supplies (Recycled Water)	Section 6.2	Section 5.7.
10633(g)	Provide a plan for optimizing the use of recycled water in the supplier's service area.	System Supplies (Recycled Water)	Section 6.2	Section 5.7.
10631(d)(1)	Quantify past, current, and projected water use, identifying the uses among water use sectors.	System Water Use	Section 4.2	Section 2.3 and 2.5. Tables 2-1, 2-2, 2-3, 2-4, 2-5.
10631(d)(3)(A)	Report the distribution system water loss for for each of the 5 years preceding the plan update.	System Water Use	Section 4.3	Not applicable.
10631(d)(3)(C)	Retail suppliers shall provide data to show the distribution loss standards were met.	System Water Use	Section 4.2	Not applicable.
10631.1(a)	Include projected water use needed for lower income housing projected in the service area of the supplier.	System Water Use	Section 4.5	Not applicable.
10632(a)	Provide a water shortage contingency plan (WSCP) with specified elements below.	Water Shortage Contingency Planning	Chapter 8	Appendix B.
10632(a)(2)(A)	Provide the written decision-making process and other methods that the supplier will use each year to determine its water reliability.	Water Shortage Contingency Planning	Section 8.2	Appendix B.
10632(a)(2)(B)	Provide data and methodology to evaluate the supplier’s water reliability for the current year and one dry year pursuant to factors in the code.	Water Shortage Contingency Planning	Section 8.2	Appendix B.

DWR Checklist for 2020 UWMP
Checklist Arranged by Subject

Water Code Section	Summary as Applies to UWMP	Subject	2020 Guidebook Location	2020 UWMP Location *(e.g. Section(s), page number(s), table/figure number(s) or briefly describe why CWC section does not apply)*
10632(a)(3)(A)	Define six standard water shortage levels of 10, 20, 30, 40, 50 percent shortage and greater than 50 percent shortage. These levels shall be based on supply conditions, including percent reductions in supply, changes in groundwater levels, changes in surface elevation, or other conditions. The shortage levels shall also apply to a catastrophic interruption of supply.	Water Shortage Contingency Planning	Section 8.3	Appendix B.
10632(a)(3)(B)	Suppliers with an existing water shortage contingency plan that uses different water shortage levels must cross reference their categories with the six standard categories.	Water Shortage Contingency Planning	Section 8.3	Appendix B.
10632(a)(4)(A)	Suppliers with water shortage contingency plans that align with the defined shortage levels must specify locally appropriate supply augmentation actions.	Water Shortage Contingency Planning	Section 8.4	Appendix B.
10632(a)(4)(B)	Specify locally appropriate demand reduction actions to adequately respond to shortages.	Water Shortage Contingency Planning	Section 8.4	Appendix B.
10632(a)(4)(C)	Specify locally appropriate operational changes.	Water Shortage Contingency Planning	Section 8.4	Appendix B.
10632(a)(4)(D)	Specify additional mandatory prohibitions against specific water use practices that are in addition to state- mandated prohibitions are appropriate to local conditions.	Water Shortage Contingency Planning	Section 8.4	Appendix B.
10632(a)(4)(E)	Estimate the extent to which the gap between supplies and demand will be reduced by implementation of the action.	Water Shortage Contingency Planning	Section 8.4	Appendix B.
10632(a)(5)(A)	Suppliers must describe that they will inform customers, the public and others regarding any current or predicted water shortages.	Water Shortage Contingency Planning	Section 8.5	Appendix B.
10632(a)(5)(B) 10632(a)(5)(C)	Suppliers must describe that they will inform customers, the public and others regarding any shortage response actions triggered or anticipated to be triggered and other relevant communications.	Water Shortage Contingency Planning	Section 8.5, 8.6	Appendix B.
10632(a)(7)(A)	Describe the legal authority that empowers the supplier to enforce shortage response actions.	Water Shortage Contingency Planning	Section 8.7	Appendix B.
10632(a)(7)(B)	Provide a statement that the supplier will declare a water shortage emergency Water Code Chapter 3.	Water Shortage Contingency Planning	Section 8.7	Appendix B.
10632(a)(7)(C)	Provide a statement that the supplier will coordinate with any city or county within which it provides water for the possible proclamation of a local emergency.	Water Shortage Contingency Planning	Section 8.7	Appendix B.
10632(a)(8)(A)	Describe the potential revenue reductions and expense increases associated with activated shortage response actions.	Water Shortage Contingency Planning	Section 8.8	Appendix B.
10632(a)(8)(B)	Provide a description of mitigation actions needed to address revenue reductions and expense increases associated with activated shortage response actions.	Water Shortage Contingency Planning	Section 8.8	Appendix B.
10632(a)(8)(C)	Describe the cost of compliance with Water Code Chapter 3.3: Excessive Residential Water Use During Drought.	Water Shortage Contingency Planning	Section 8.8	Appendix B.
10632(a)(9)	Retail suppliers must describe the monitoring and reporting requirements and procedures that ensure appropriate data is collected, tracked, and analyzed for purposes of monitoring customer compliance.	Water Shortage Contingency Planning	Section 8.9	Appendix B.
10632(a)(10)	Describe reevaluation and improvement procedures for monitoring and evaluation the water shortage contingency plan to ensure risk tolerance is adequate and appropriate water shortage mitigation strategies are implemented.	Water Shortage Contingency Planning	Section 8.10	Appendix B.
10632(b)	Analyze and define water features that are artificially supplied with water, including ponds, lakes, waterfalls, and fountains, separately from swimming pools and spas.	Water Shortage Contingency Planning	Section 8.11	Appendix B.
10620(f)	Describe water management tools and options to maximize resources and minimize the need to import water from other regions.	Water Supply Reliability Assessment	Section 7.4	Section 4.6.
10634	Provide information on the quality of existing sources of water available to the supplier and the manner in which water quality affects water management strategies and supply reliability	Water Supply Reliability Assessment	Chapter 7	Section 6; Tables 6-1, 6-2.

Section 1: Overview of 2020 IEUA Water Shortage Contingency Plan

The Inland Empire Utilities Agency (IEUA) is a wholesale water agency that treats and delivers recycled water and purchases imported water supplies[1] from Metropolitan Water District of Southern California (MWD) and distributes it to its seven retail agencies. Two of IEUA's retail water agencies, [Fontana Water Company (FWC) and Cucamonga Valley Water District (CVWD)] purchase untreated water directly from IEUA and provide their own treatment. Five of IEUA's retail water agencies purchase treated water from the Water Facilities Authority (WFA). WFA purchases untreated imported water from IEUA, treats and delivers the water to the cities of Chino, Chino Hills, Ontario, Upland, and Monte Vista Water District. IEUA does not operate any facilities connecting its retail water agencies to MWD's system.

MWD water supplies account for approximately 25 to 30% of the region's annual water supplies, plus additional water is stored by MWD in the Chino Basin for use in dry years. Each of the retail agencies has other water sources including groundwater and local surface water. Each retail agency has agency-specific Water Shortage Contingency Plans (WSCPs) that account for the reliability of each suppliers' unique water portfolio. The IEUA WSCP focuses on a regional representation of the reliability of imported water supplied by MWD with additional supply reliability from IEUA's recycled water supplies and then outlines the actions that IEUA may take to support its retail agencies during water shortage conditions. The WSCP may also apply to more generalized water shortage conditions that are not necessarily attributable to imported water shortages.

This WSCP is founded on several IEUA source documents, including the 2020 Regional Drought Contingency Plan (2020 DCP, included in WSCP Appendix A), the draft 2020 Water Use Efficiency Business Plan (WUEBP), the Annual Water Use Efficiency (WUE) Reports, and the 2010 and 2015 Urban Water Management Plans. In addition, there is overlapping content with the 2020 UWMP, especially the Supply Reliability (UWMP Section 4). It also draws upon the MWD 2020 WSCP.

This WSCP covers the required elements as set forth by CWC Section 10632. It should also be noted that statute recognizes the WSCP as viable a tool for use during drought emergencies as noted in Water Code section 10632.3 indicating that the State defers to the locally adopted WSCP to the extent practicable.

[1] As of this writing, all MWD supplies are from imported water sources. However, MWD is considering a potential 150 mgd potable reuse project. For more information, please see mwdh2o.com/rrwp

Because IEUA is a wholesale urban water supplier, some of the elements that pertain only to retail water suppliers may not be addressed in this WSCP[2]. For example. IEUA's WUEBP, which is updated every 5 years and Annual WUE Reports, address monitoring and tracking of WUE measures implemented which is not a requirement of wholesalers.

This WSCP document contains 11 sections. The first section is an introduction that explains the purpose of the WSCP and gives background on IEUAs service area. Section 2 is a summary of the water reliability available to IEUA, pursuant to CWC Section 10635. Section 3 is a description of the Annual Water Supply and Demand Assessment (Annual Assessment). Section 4 explains the WSCP's six standard water shortage levels and the relationship to the DCP shortage stages. Section 5 describes the WSCP's shortage response actions that align with the defined shortage levels and the evaluation of effectiveness. Section 6 addresses communication protocols and procedures to inform customers, the public, interested parties, and local, regional, and state governments, regarding any current or predicted shortages and any resulting shortage response actions. Section 7 describes mechanisms to determine water use reductions. Section 8 is a description of the financial consequences of and responses for drought conditions. Section 9 describes actions to prepare for catastrophic interruption. Section 10 addresses reevaluation and improvement procedures for monitoring and evaluating the functionality of the WSCP. Section 11 describes the process to adopt, submit, and amend the WSCP.

It is important to note that outcomes of the various planning processes are not a "cast in stone" series of actions that become mandated procedures, requiring stakeholder adherence. Instead, the plan acts as a resource and general guide for IEUA and its retail agencies. It is understood that each retail agency has its own distinct supply portfolio, operating principals, and customer characteristics. As such, there may be instances when a retail agency is not experiencing the same drought or water shortage impacts and will choose to take a modified course of action. As summarized in WSCP Section 5 and detailed in the DCP, a Drought Response Taskforce of staff from IEUA and its retail agencies may be convened in the event of a water shortage to identify the specific actions of IEUA and the retail agencies as appropriate to the particular shortage condition.

1.1 Relationship to the Urban Water Management Plan

Water Code Section 10632(a) requires that every urban water supplier prepare and adopt a water shortage contingency plan as part of its urban water management plan. While the water shortage contingency plan is a stand-alone document it is updated and adopted in concert with the UWMP. Content of the WSCP is informed by the analysis of water supply reliability conducted pursuant to Water Code Section 10635 (contained in the UWMP). The reliability analysis of the UWMP considered under "normal", "single-dry", and "5-year drought" conditions.

---

[2] WSCP elements that apply specifically to retailer water suppliers are: (1) a description of customer compliance, enforcement, appeal, and exemption procedures for triggered response actions [CWC Section 10632(a)(6)]; (2) a description of the cost of compliance with Chapter 3.3 (commencing with Section 365) of Division 1 [CWC Section 10632(a)(8)(c)]; and (3) monitoring and reporting requirements and procedures that ensure appropriate data is collected, tracked, and analyzed for purposes of monitoring customer compliance and to meet state reporting requirements [CWC Section 10632(a)(9)] (MWD 2020).

The analysis in the UWMP documents that the IEUA region has sufficient supplies to meet normal, single-dry, and multi-dry-year demands. An area of overlap between the UWMP and WSCP is a new requirement to prepare a Drought Risk Assessment (DRA) (Section 7.5 of the 2020 UWMP) to account for the significant duration of recent California droughts and the predictions about hydrological variability attributable to climate change.

The DRA requires suppliers to assess water supply reliability over a 5-year period from 2021 to 2025 that examines water supplies, water uses, and the resulting water supply reliability under a reasonable prediction for 5 consecutive dry years. Table 1-1 (Table 7-7 in the UWMP) shows the expected gross water use [in acre-feet (AF)] and the expected total supplies for each year from 2021 to 2025. The water supplies and demands were aggregated on a regional basis to reflect the entire IEUA service area. The gross water use for each year was found by interpolating between the 2020 actual regional water demand total (from the FY 19/20 Annual Water Use Report and the FY 19/20 Recycled Water Annual Report) and the 2025 projected water use during a multiple-year drought (from UWMP Table 7-7).

As shown in Table 1-1, the IEUA region expects to have a surplus for each of the 5 years of the consecutive 5-year drought from 2021-2025. Therefore, no Water Shortage Contingency Plan actions are anticipated to be implemented. However, in the case of a shortfall in supply, the use reduction and supply augmentation measures described in Section 5 of this WSCP are available to be implemented.

Table 1-1: DWR Five-Year Drought Risk Assessment Tables to Address Water Code Section 10635(b) (DWR Table 7-5)

2021	Total
Total Water Use (AF)	99,898
Total Supplies (AF)	148,650
Surplus/Shortfall w/o WSCP Action (AF)	48,752
Planned WSCP Actions (use reduction and supply augmentation)	
WSCP - supply augmentation benefit (AF)	0
WSCP - use reduction savings benefit (AF)	0
Revised Surplus/(shortfall) (AF)	**48,752**
Resulting % Use Reduction from WSCP action	0%
2022	**Total**
Total Water Use (AF)	103,850
Total Supplies (AF)	149,806
Surplus/Shortfall w/o WSCP Action (AF)	45,957
Planned WSCP Actions (use reduction and supply augmentation)	
WSCP - supply augmentation benefit (AF)	0
WSCP - use reduction savings benefit (AF)	0
Revised Surplus/(shortfall) (AF)	**45,957**
Resulting % Use Reduction from WSCP action	0%

2023	Total
Total Water Use (AF)	107,958
Total Supplies (AF)	150,972
Surplus/Shortfall w/o WSCP Action (AF)	43,014
Planned WSCP Actions (use reduction and supply augmentation)	
WSCP - supply augmentation benefit (AF)	0
WSCP - use reduction savings benefit (AF)	0
Revised Surplus/(shortfall) (AF)	**43,014**
Resulting % Use Reduction from WSCP action	0%
2024	**Total**
Total Water Use (AF)	112,228
Total Supplies (AF)	152,146
Surplus/Shortfall w/o WSCP Action (AF)	39,918
Planned WSCP Actions (use reduction and supply augmentation)	
WSCP - supply augmentation benefit (AF)	0
WSCP - use reduction savings benefit (AF)	0
Revised Surplus/(shortfall) (AF)	**39,918**
Resulting % Use Reduction from WSCP action	0%
2025	**Total**
Total Water Use (AF)	116,667
Total Supplies (AF)	153,329
Surplus/Shortfall w/o WSCP Action (AF)	36,662
Planned WSCP Actions (use reduction and supply augmentation)	
WSCP - supply augmentation benefit (AF)	0
WSCP - use reduction savings benefit (AF)	0
Revised Surplus/(shortfall) (AF)	**36,662**
Resulting % Use Reduction from WSCP action	0%

Note: Years 2021 through 2024 are interpolated between the 2020 actual supply and use values and the 2025 projected supply and use for multi-year drought (from Table 7-4). 2020 actual supply is the average year supply from Table 7-1.

Section 2: Water Supply Reliability Analysis

This section addresses overall water supply reliability for IEUA and meets Water Code Section 10635. Information from the 2010 UWMP which focused on IEUA's role as a wholesaler, information from the 2015 UWMP which included IEUA and Water Facilities Authority (WFA), a retailer, and information from Section 4 of the 2020 UWMP, the 2020 DCP and MWD's draft WSCP issued in February 2021 are used to analyze supply reliability for this section. MWD has taken the lead in drought planning for the southern California region. This is particularly relevant to IEUA, as IEUA is a wholesaler of MWD water.

2.1 MWD Water Supply Reliability

As described in MWD's draft WSCP issued in March 2021, MWD continuously engages in planning for various aspects of its water management, including operations, long-term reliability, and emergency response. These MWD planning efforts include the 1996 Integrated Water Resources Plan (MWD IRP) and its three updates in 2004, 2010, and 2015; the 2020 MWD IRP (currently in development); the draft 2020 WSCP; the annual Water Surplus and Drought Management (WSDM) Plan; the Water Supply Allocation Plan (WSAP); the annually calculated Emergency Storage Objective; and the 2020 Seismic Risk Assessment and Mitigation Plan. These efforts provide a policy framework, operating guidelines, and resource targets for MWD to ensure regional water supply reliability. MWD's WSCP is designed to be consistent with its WSDM Plan and WSAP as described below.

2.1.1 Water Surplus and Drought Management Plan

In 1998, MWD's Board of Directors adopted the WSDM Plan, which addresses both surplus and shortage operating strategies (reference MWD WSDM Plan, April 1998). The WSDM plan reflects anticipated drought responses based on the water supplies available to Metropolitan. Similar in concept to MWD's WSCP, the WSDM Plan provides an overall vision for operational supply management and characterizes a flexible sequence of actions to minimize the probability of severe shortages and reduce the likelihood of extreme shortages. WSDM Plan principles guide the specific actions to be taken under MWD WSCP shortage stages. Data collection, continual analysis, and monthly reporting processes of WSDM Plan implementation will form the basis for MWD's Annual Water Supply Demand Assessment that will be provided annually to the state beginning in July 2022. Because managing MWD's water supply resources requires timely and accurate information on supply and demand conditions that change throughout the year, MWD evaluates available water supplies and existing water storage levels on a monthly basis to determine the appropriate actions identified in the WSDM Plan.

Table 2-1 (referenced from the 2010 MWD UWMP) lists the definitions used by MWD in the WSDM Plan for surplus, shortage, severe shortage, and extreme shortage conditions. Except in severe or extreme shortages or emergencies, MWD's resource management will allow imported water shortages to be mitigated without impacting municipal and industrial customers, including IEUA and IEUA's retail agencies. The WSDM Plan is detailed in Chapter 4 of the MWD UWMP.

Table 2-1: MWD WSDM Plan Definitions

Surplus	Metropolitan can meet full-service and interruptible program demands, and it can deliver water to local and regional storage.
Shortage	Metropolitan can meet full-service demands and partially meet or fully meet interruptible demands, using stored water or water transfer, as necessary.
Severe Shortage	Metropolitan can meet full-service demands only by using stored water, transfers, and possibly calling for extraordinary conservation. In a Severe Shortage, Metropolitan may have to curtail Interim Agricultural Water Program deliveries.
Extreme Shortage	Metropolitan must allocate available supply to full-service customers.

The shortage stages presented in this section apply to IEUA's imported water supply only. The water shortage actions specific to IEUA's water shortage stages are discussed in Section 5.

2.1.2 Water Supply Allocation Plan

MWD's Board of Directors also adopted the WSAP in February 2008 in anticipation of possible water supply shortages. The WSAP provides guidance for allocating limited water supplies to member agencies should the need arise. The WSAP is integral to MWD's WSCP's shortage response strategy in the event that MWD determines that supply augmentation (including storage) and demand reduction measures would not be enough to meet a projected shortage.

MWD's WSAP was developed in consideration of the principles and guidelines in MWD's 1999 WSDM Plan. The WSAP's formula seeks to balance the impacts of a shortage at the retail level while still maintaining equity at the wholesale level for supply shortages of up to 50 percent (%). The formula takes into account the impact on retail customers and the economy, growth and population, changes in supply conditions, investments in local resources, demand hardening aspects of non-potable recycled water use, implementation of conservation savings program, participation in MWD's interruptible programs, and investments in facilities.

In order to implement the WSAP, the MWD Board annually determines the level of the regional shortage based on specific criteria each April; this information is incorporated into IEUA's Annual Water Supply and Demand Assessment discussed in MWD WSCP Section 3. MWD's allocations, if deemed necessary, go into effect in July of the same year and remain in effect for a 12-month period. The WSAP includes an annual review of all MWD supplies and regional shortages to determine overall reliability for the year under review.

The WSAP is MWDs policy and formula for equitably allocating available water supplies to the member agencies during extreme water shortages when MWD determines it is unable to meet all its demands.

2.1.3 Emergency Storage Objective

The MWD Emergency Storage Objective, which is the regional planning estimate for emergency storage, is based on the potential for a major earthquake that would damage all supply aqueducts, isolating Southern California from its imported water sources, or a similar disaster.

In 2019, MWD and its member agencies completed a process to update the planning estimate of MWD's Emergency Storage Objective. This emergency storage represents the amount of water that MWD would store for the region in preparation for a catastrophic earthquake that would damage the aqueducts that transport imported water supplies to Southern California, including: the Colorado River Aqueduct, both the East and West branches of the California Aqueduct of the State Water Project (SWP), and the Los Angeles Aqueduct. The emergency storage allows MWD to deliver reserve supplies to the member agencies to supplement local production. This helps avoid severe water shortages during periods when the imported water aqueducts may be out of service.

Beginning January 2020, CWC Section 10632.5 mandates that urban water suppliers include in their UWMP a seismic risk assessment and mitigation plan to assess the vulnerability of each of the various facilities of a water system and mitigate those vulnerabilities. For IEUA, this requirement was addressed as part of developing its resilience strategy and is presented in detail in MWD's seismic resiliency reports in Appendix 9 to MWD's 2020 UWMP.

2.2 IEUA Water Supply Reliability

IEUA's imported water supply reliability is directly tied to MWD's supply reliability and if imported shortages occur, MWD uses the WSAP to allocate the available water. Fortunately, IEUA's exposure to potential MWD shortages is minimized in that imported water represents only 25 to 30%of the total regional supplies. Member agencies have rights to local surface and groundwater for the remaining 70 to 75% of the supply needed. Moreover, IEUA provides recycled water and is able to capture stormwater during rain events to replenish the Chino Basin to maximize water reuse and offset potable water demands. The 2020 DCP included a detailed analysis to evaluate potential impacts of book end or worst-case water supply shortages in the IEUA service area; the DCP Scenarios 2 and 3 considered the following:

1. **Imported water was reduced by 67.5% (Shortage Allocation Index 9 of MWD's WSAP)** In the 2020 DCP Scenario 2 analysis, which assumed local supplies were still available, the region had an overall surplus of water supply, while three agencies that depend heavily on imported water resulted in potential shortages. The 2020 DCP Scenario 3 assumed reductions in imported and local supplies as a result of a 5-year drought. DCP Scenario 3 predicted that while two agencies showed surpluses, overall, the region has a deficit of 13% of demand with current supplies. Under DCP Scenario 3, the loss of 67.5% of the imported water supply will result in the increased reliance on local surface and groundwater sources with associated water quality impacts. The ability to use some local wells may be affected by two water quality factors as detailed in item 2 below. It should be noted that MWD's IRP indicates only one scenario in which significant shortages would be anticipated to occur; the scenario assumed no future investments which is a conservative assumption. In fact, MWD continues to provide investments towards the development of local supply projects and is considering investments in Delta conveyance and a 150 million gallon per day (mgd) Regional Recycled Water facility in-region that may further improve MWD's overall water supply reliability and minimize the occurrence of requiring a MWD WSAP Shortage Allocation Index 9. Additionally, it should be noted that demands on MWD for water supplies has dropped in half from a high of approximately 2.4 million acre-feet per year to approximately 1.2 million acre-feet today. This remarkable reduction in demand for

MWD's water supplies is due to reductions in water use at the customer level along with the development of local supply projects throughout MWD's service territory.

2. **Reductions in local supply, due to potential impairments to groundwater quality, pose the most significant water reliability risk to the IEUA service area**. Nearly all the retail agencies rely on local groundwater to meet their annual demands. DCP Scenario 3 results indicate that agencies with groundwater supplies that currently require blending lose higher quality imported blending water and agencies with impaired supplies that do not require blending would be required to blend as groundwater quality declines. Therefore, conditions related to groundwater quality and reduced water available for blending could reduce the availability and reliability of groundwater in the future. DCP Scenario 3 illustrates that reduced groundwater quality combined with a loss of imported water could cause significant shortages for multiple agencies within the service area.

It should be noted that the 2020 DCP is a forward-looking planning document that provides insight for potential future 2035 conditions for IEUA and its retail agencies. The Drought Risk Assessment for 2021-2025 presented in Section 1, is based on MWD's estimates of supply availability for the near future which does not anticipate that longer-term worst-case conditions as described in the 2020 DCP will occur.

Section 3: Annual Water Supply and Demand Assessment Procedures

This section describes annual supply and demand assessment procedures, known as the Annual Assessment, to be performed by IEUA and submitted to DWR each year starting on July 1, 2022. The information in this section is highly reliant on the analyses presented in the 2020 DCP and UWMPs. IEUA will coordinate with both MWD and its retail agencies to meet the annual water supply and demand requirements of Water Code Section 10632(a)(2).

3.1 Drought Monitoring

The framework for drought monitoring largely relies on the knowledge and expertise of IEUA's retail agencies in order to interpret real time local conditions and analyze future supplies. IEUA's role is to act as a facilitator and gather supply data from all retail agencies, consolidate all collected data, and calculate the supply-demand index. Additionally, IEUA tracks potential imported water shortages through MWD and the MWD Board's annual determination each April of the level of the regional shortage based on the WSAP criteria. It is important to note that supply types and portfolios within the IEUA service area are extremely diverse and availability of supply types are dependent on several different factors.

The four primary components of the drought monitoring framework are outlined in the IEUA 2020 DCP and are as follows:

- **Indicator Data Collection and Distribution.** Key imported water availability indicators will be compiled and provided to the retail agencies annually.

- **Member Agency Reporting**. Based on the provided indicator data and their own monitoring activities, participating retail agencies will provide their annual projections for supplies and demands within their service area once a year.

- **Regional Supply-Demand Index Calculation**. The agency projections will be combined to formulate a regional supply-demand ratio (or index). The Supply-Demand Index Calculation is further described in Section 3.2.

- **Shortage Classification.** The regional index will be used to classify the level of water shortage (if any).

The monitoring framework allows current and projected water supplies to be compared against current and projected demands. Should there be a downward shift in available water supplies or an increase in customer demand, IEUA and its retail agencies will determine the severity of the change, the categorized stage level, and the required response. Figure 3-1 gives a graphic representation of the monitoring framework.

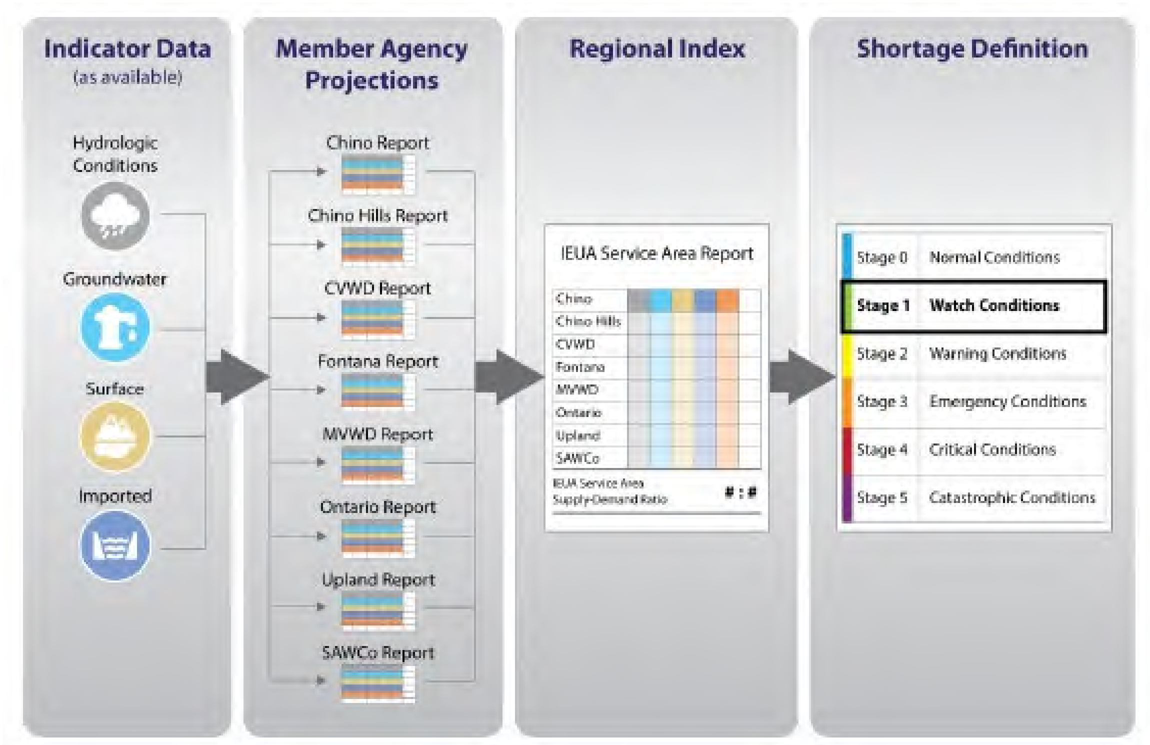

Figure 3-1: IEUA Regional Drought Monitoring Framework (2020 DCP)

3.1.1 Regional Collaborative Reporting Framework

IEUA has an established regular forum to provide and receive updates from the retail agencies on water supply conditions. Retail agencies submit annual data regarding water demands for the prior year between July and August of each year. IEUA hosts regular meetings with retail agency General Managers and IEUA also communicates with retail agency Water Managers in meetings that occur on an as-needed basis. Prior to 2020, the Water Managers typically met every 2 months. These meetings serve as a forum wherein the Water Managers review supply conditions, demand shifts, and regulatory changes that may impact supply. IEUA also prepares a Newsletter for retail agencies to communicate imported water and other regulatory conditions. If local circumstances or external drivers significantly shift, IEUA will request updated local supply data from respective retail agencies. As with the annual reporting, this information will be used to determine whether there is a regional water shortage due to these factors.

IEUA's monitoring process specific to drought will be based on an annual determination of potential drought shortage conditions, triggering the formation of a regional Drought Response Task Force that will meet periodically, as conditions warrant, and will trigger a two-step decision-making process as follows:

1. Key water supply indicators for imported water, discussed in Section 3.2, will be compiled into a standardized report and distributed to the water managers from each retail agency. A meeting with Water Managers' may be convened if needed. This will include projected deliveries of imported water from MWD as described in Section 3.2 in

addition to any potential forecasts for shortages. IEUA will also provide estimated demand projections to the participating retail agencies, as a reference or guide, based on a 5-year historical average.

2. Each retail agency will report their projected local supplies and demand for the coming year to IEUA. Table 3-1 below is a sample of the information obtained from each retail agency used to generate the supply-demand ratio.

Table 3-1: Sample Reporting Framework for IEUA Member Agencies (2020 DCP)

Agency	Local Groundwater	Surface Water	Imported Water	Annual Demand	Supply Shortage
Chino					
Chino Hills					
Fontana Water Company					
Ontario					
Upland					
Cucamonga Valley Water District					
Monte Vista Water District					
San Antonio Water Company					

This reporting process and structure was selected because it uses the annual reporting timeframe conducted by IEUA, the retail agencies, and MWD.

3.2 Imported Water WSAP Monitoring

IEUA began importing supplemental Colorado River water to the Chino Basin from MWD in 1951. In the late 1970's, MWD began delivering water from northern California via the State Water Project (SWP), offering IEUA an opportunity to connect to MWD's Rialto pipeline and switch to 100% SWP supplies after disconnecting from MWD's Upper Feeder pipeline as shown on Figure **3-2** that follows. The SWP became IEUA's exclusive source of imported water supplies in order to achieve groundwater quality requirements.

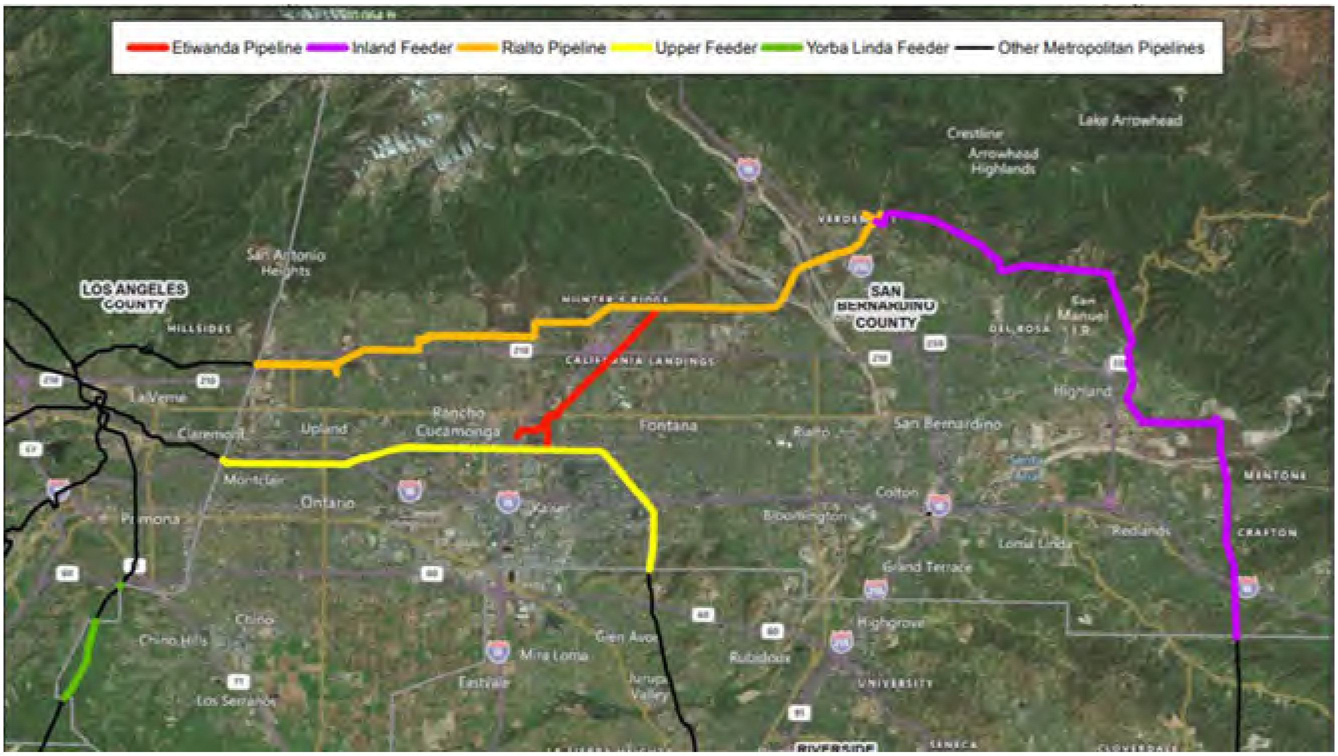

Figure 3-2: MWD Imported Water Pipeline Network

The SWP originates along the Feather River (a tributary to the Sacramento River) hundreds of miles north of IEUA. The SWP utilizes facilities to pump and convey water from the Sacramento-San Joaquin River Delta (Delta) to Southern California, as well as to the San Francisco Bay Area, the San Joaquin Valley, and the Central Coast. From 2009 to 2018, SWP imported water supplies delivered by MWD account for roughly 25-30% of the water supplies in the IEUA service area.

MWD actively monitors and manages the water supplies it imports to the region to assess availability and predict shortages. In response to critically dry conditions in the early 2000s and federal court rulings to protect the Delta Smelt in 2007 (which tightened regulations on Delta exports), as discussed in Section 2.1.2, MWD developed the WSAP to help manage uncertainty in the future water availability from their portfolio of sources and storage. Should a water shortage be declared by MWD's Board, the WSAP establishes MWD member agency supply allocations in a fair and reasonable way based on pre-determined formulas and key implementation elements needed to administer an allocation.

The framework of the WSAP includes an allocation year that spans from July to June, with a declaration in April. The key dates for MWD's WSAP monitoring and declaration process include the following:

January to March: Water Surplus and Drought Management reporting process provides updated information on storage reserve levels, projected supply, and demand conditions to the MWD Water Planning and Stewardship Committee meetings. Consideration of a potential allocation situation would be announced during this time.

April: Assuming supply conditions did not improve, MWD member agencies would report their projected local supplies for the coming allocation year (July to June) to update MWD's projected total supplies. Staff analysis of MWD storage reserves and projected supply and demand conditions would provide an allocation recommendation to the MWD Board of Directors. The allocation would be effective starting July 1 and held through the following June 30.

A 10-level WSAP Shortage Allocation Index would determine the Wholesale Minimum Allocation and the Maximum Retail Impact Adjustment. A "Wholesale Minimum Allocation" is defined as the minimum amount of MWD-supplied wholesale water service provided to each member agency. The Maximum Retail Impact Adjustment ensures that agencies with a high level of dependence on MWD do not encounter unequal retail shortages when experiencing a reduction in wholesale supplies.

In addition to the Wholesale Minimum Allocation and Retail Impact Adjustment, a Conservation Demand Hardening Credit and Minimum Per-Capita Water Use Credit would be considered to determine each Member Agency's WSAP Allocation. The allocation to an agency for its municipal and industrial retail demand is the sum of the above described four components, which are described in detail in the Appendix of the WSAP.

July to June: Member agencies would be requested by MWD to submit their local production on a monthly basis and certify the end of allocation year local supply use. Local production data must be reported to MWD by the end of the month following the month of use (i.e., use in July must be reported by the end of August). The production and supply use information is then combined with MWD sales information to track retail water use throughout MWD's service area. Each month, MWD reports on member agency water sales compared to their allocation amounts.

June 30: Allocation year would be complete.

August: MWD calculates potable water use based on supply certifications and actual sales data for the previous allocation year (July to June). Allocation surcharges are assessed for usage above a given member agency's final adjusted allocation.

It is important to note that while MWD's analysis focuses on combined SWP and Colorado River supply sufficiency, it is capable of focusing singularly on SWP-only supply sufficiency for IEUA and any other SWP-exclusive member agencies, if needed.

3.3 Supply/Demand Ratio

As detailed in the 2020 DCP, the supply and demand ratios for each year will be calculated based on the projections provided by the water managers. The data will be compiled into a singular supply-demand ratio for the IEUA service area and reported to the Water Managers. The regional supply-demand ratio calculation and a comparison to the DCP Drought Stages, discussed in Section 4 will then assist in determining whether there is a regional water shortage requiring action.

Figure 3-3 provides an example compilation of member agency projections and calculation of the regional supply-demand ratio. There will be considerations for expected shortages for individual retail agencies that may not be reflected in the regional ratio.

Between reporting periods, the participating retail agencies will continue their individual monitoring activities. Each of the retail agencies have developed their own approach to monitoring their supplies and have established unique definitions and responses for localized shortage conditions. "Appendix B: Summary of Member Agency Water Shortage Stages" in the 2020 DCP provides an overview of each agencies' shortage definitions and responses.

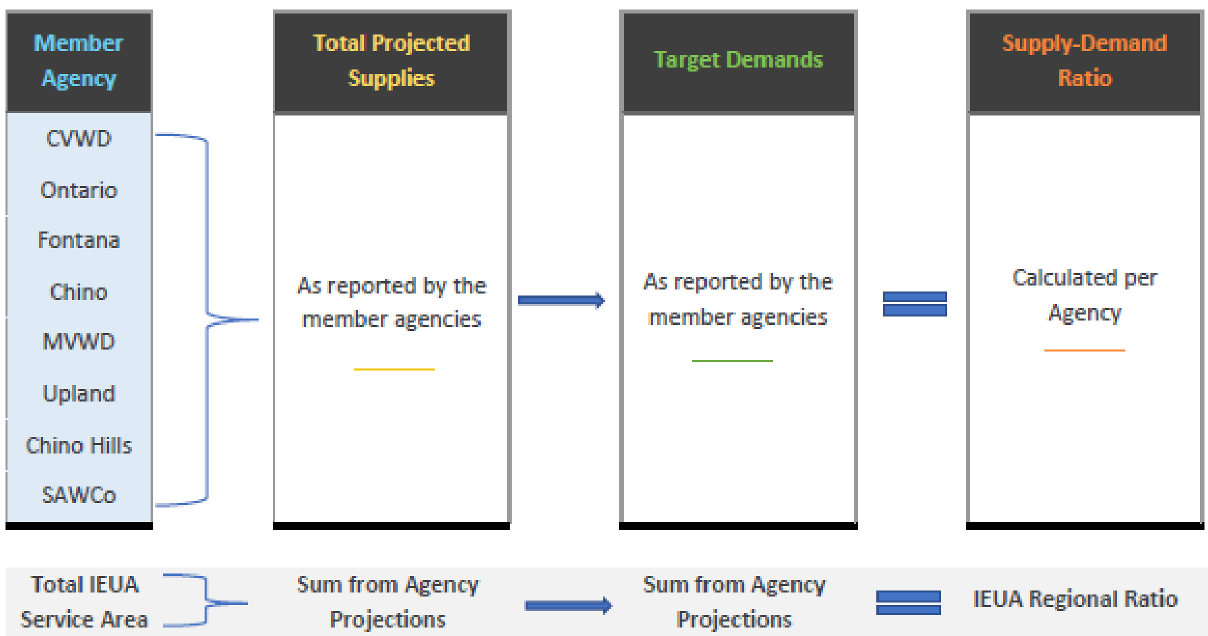

Figure 3-3: Annual Regional Supply and Demand Projections for IEUA Service Area (2020 DCP)

Section 4: Shortage Stages

This section describes the water shortage stages as defined by IEUA. The water shortage stages presented meet the requirements of Water Code Section 10632(a)(3).

4.1 Overview of Shortage Stages

The water shortage stages described in this section are in compliance with state legislation (SB 606 and AB 1668), which now requires drought plans to be standardized, as well as include six stages of drought severity. These stages were developed in consultation with each of the member agency's own definitions for local drought or water shortage levels and can be viewed in "Appendix B: Summary of Member Agency Water Shortage Stages" in the IEUA 2020 DCP. Additionally, each member agency may have their own Water Shortage Contingency Plan for use at the retail level.

The Water Shortage Stages are defined based on the calculated supply-demand ratios for the IEUA service area and are shown into DWRs shortage levels.

Table 4-1. These stages are used to help the Drought Response Taskforce identify the most appropriate regional responses for the anticipated shortages. Table 4-1 also contains the cross reference from the DCP shortage stage to DWRs shortage levels.

Table 4-1: IEUA Regional Water Shortage Stages (IEUA, 2020) Cross Reference with DWR Shortage

2020 DCP			2020 WSCP PER DWR	
Drought Stage	**Stage Descriptions**	**Triggers**	**2020 WSCP Level**	**Shortage Level**
Stage 0	Normal Conditions	No water shortages anticipated.	-	
Stage 1	Watch Conditions	IEUA regional ratio is predicting shortages between 1% and 5%.	1	≤10%
Stage 2	Warning Conditions	IEUA regional ratio is predicting shortages between 6% and 15%.	2	10 – 20%
Stage 3	Emergency Conditions	IEUA regional ratio is predicting shortages between 16% and 25%.	3	20 – 30%
Stage 4	Critical Conditions	IEUA regional ratio is predicting shortages between 26% and 50%.	4 5	30 – 40% 40 – 50%
Stage 5	Catastrophic Conditions	IEUA regional ratio is predicting shortages greater than 50%.	6	>50%

It is important to note that while the water shortage stage at the time of a drought is calculated and declared for the overall region, a local retail agency may have a water supply level that varies from the regional stage due to the uniqueness of their water supply mix. When this occurs, the local agency may develop customer messaging that is specifically applicable to their retail service area.

4.2 Water Shortage Stage Declaration

In the event of an emergency, IEUA may declare a Water Shortage Emergency and assemble the Drought Response Taskforce who will help inform the decision with tasks that include reviewing regional shortage conditions, deciding regional actions, budget generation and an implementation timeline. Coordination efforts may include retail agencies, MWD, Board of Directors, and regional stakeholders.

Typically, IEUA implements various stages of conservation actions based on the degree of water shortage before a state emergency is declared. If an emergency declaration is made, IEUA will coordinate with both its retail agencies and MWD to comply with all governing regulations. An unexpexted or sudden loss of water supplies may result in the expidited declaration of a water shortage emergency and associated activities.

Section 5: Shortage Response Actions (by Water Shortage Stage)

This section describes the water shortage stage response actions as defined by IEUA and are based on IEUA's definitions of the water shortage stages. The response actions presented in this section are heavily reliant on the 2020 DCP and its UWMPs. The response actions meet the requirements of Water Code Section 10632(a)(4).

5.1 Shortage Response Actions Overview

With growing populations and the inevitability of future drought cycles, IEUA, has invested in local supply and demand management programs with the aim of building regional, long-term resiliency to drought and climate change that will aid the region to be able to withstand future water shortages without extreme hardships.

By leveraging funding and programs from MWD and other regional stakeholders, IEUA and its retail agencies have partnered to help reduce per capita water use by re-shaping customers' attitudes about water use efficiency and their personal role in achieving water shortage resiliency. Through education, messaging, and investments of approximately $1.6 million, annually in water use efficiency programs, IEUA has been assisting customers to make significant equipment and lifestyle changes at their homes and businesses. The more our region is able to be self-sufficient with its water supplies, the less impactful any imported water supply shortages will be.

In 2018, California chaptered into law legislation (AB 1668 and SB 606) requiring all retail water agencies to annually establish a Water Use Objective (WUO) that will serve as a standard for assuring community-wide water-use efficiency. Each of IEUA's retail water agencies is required to submit their WUO's to a State agency by November 2023. If actual water use in their service territory is lower than their WUO, then that agency's customers are considered to be using water efficiently. Some assumed values in the calculation of the WUO will reduce over time, such as the assumed per capita water used indoors in residential properties, which will start at 55 gallons per capita per day (gpcd) in 2023 and reduce to 50 gpcd after 2030. The penalty for non-compliance is up to $10,000 per day per retail water agency.

Beyond regional efforts to establish efficient water-use practices and sustainable lifestyles, extraordinary conservation may be required during periods of droughts or during other water shortages, in order to reduce regional demands sufficiently to meet allocation goals. This will need to be driven by an escalation in marketing, increased programming and services, and enhanced incentives that increase as drought stages escalate. Also, MWD and potentially the retail agencies have the option to institute water pricing mechanisms to encourage reduced water use during shortage conditions.

Several response actions for achieving extraordinary conservation are available and can be deployed relatively quickly, including increased customer messaging content and frequency, expanded outreach channels, enhanced water-use efficiency incentives and programs, and as necessary, water usage restrictions and pricing mechanisms as detailed below. Future responses to future water shortage considerations should be mindful, however, of the effects that “demand hardening” will have on the customers’ ability to reduce water use. Demand hardening recognizes that as per capita water uses reduce down towards health and safety standards, there will be fewer discretionary uses of water that can be curtailed.

During water shortage conditions, IEUA makes itself available to assist retail agencies in implementing certain actions to alert the region to the need for extraordinary conservation by the measures identified below, , most of which are existing programs.

- **Messaging:** Creative and attention-grabbing content are needed to secure customers’ attention and motivate them to take action. Public Service Announcements (PSAs) are an effective tool for messaging the civic responsibility for undertaking extraordinary conservation efforts during water shortage conditions.

- **Expanded Outreach:** Customer attitudes and expectations continue to evolve over time. In our customer-centric world, water agencies are competing for attention. Grabbing attention requires a modern approach to outreach, including social media and potentially influencer marketing. As the need for reduced demands continues and intensifies, cities and counties and other large water users such as CalTrans will be encouraged to reduce irrigation of public lands and other highly visible reductions in water use may be required to intensify the call for reductions in per capita water use.

- **Programs:** Water efficiency programs provide customers with the means and guidance to lower their properties’ water usage. Customer-friendly programs, higher incentives, direct installation options, and strong support services drive stronger response rates. The greater the services and incentives, the greater the customer response.

- **Restrictions:** Watering restrictions further reduce water-use while reinforcing the message of community importance of “doing your part”, are highly effective in securing immediate water savings, and are a powerful tool for agencies. However, they set an authoritarian tone, which may result in negative public perceptions if the rationale is not well defined.

The Drought Taskforce, described in Section 5.7.2, can be convened to focus and coordinate the activities related to shortage response actions between IEUA and the retail agencies.

5.2 Strategy Per Drought Stage

Different drought stages require varying strategies. In general, drought actions will expand as drought stages escalate. As increased drought stages are declared, agencies may increase customer support and provide a higher level of program incentives and services.

Once a drought enters a specific stage, the Taskforce will assemble to finalize the Response Plan for that stage, begin the implementation process for target-marketing and increased outreach. The DCP stages and actions are summarized below and are included in Table 5-1 by stage and DWR’s defined drought response actions.

- **At DCP Stage Zero**, a non-drought stage, programs and incentives will continue to be offered to customers at standard levels. During this time, the goal will be to encourage and incentivize customers to create drought sustainable properties in advance of an emergency. The focus will be on turf replacement programs and customer education offerings.

- At **DCP Stage 1 (1-5% decrease),** customers and micro-target high potential customers will be profiled, utilizing messaging that will best resonate with those customers.

- The strategic focus for **DCP Stage 2 (6-15% decrease)** is to expand activity for irrigation equipment and direct installation programs, and to ramp up influencer marketing.

- Tactics for **DCP Stage 3 (16-25% decrease)** require incentive increases for landscape and irrigation measures, and an expansion in customer outreach.

- **DCP Stage 4 (26-50% decrease)** requires heightened messaging of urgency and put forth a community “call to action”. Additionally, there will be an increase in penalties, implementation of emergency alerts, and expanded news media coverage.

- During **DCP Stage 5 (water use for essential functions only), IEUA may consider modifying or suspending landscape and irrigation programs to focus** on indoor plumbing, property leak detection programs and other associated efforts. All landscape and irrigation programs will be suspended, and IEUA will implement crisis messaging, announcing water for essential use only.

Table 5-1 Demand Reduction Actions (DWR Table 8-2)

Shortage Level	Demand Reduction Actions	How much is this going to reduce the shortage gap? *Include volume units used.*	Additional Explanation or Reference *(optional)*	Penalty, Charge, or Other Enforcement?
1	Expand Public Information Campaign	Minimum 1-5% of water use	Begin outreach, appealing to civic duty to reduce water use, identify high water waste reduction potential customers. Develop messaging that will best resonate with those customers	No
1	Provide Rebates on Plumbing Fixtures and Devices		SoCal WaterSmart Residential and Commercial Rebates	No
1	Provide Rebates for Landscape Irrigation Efficiency		Residential Irrigation Tune-Up, Home Surveys, Landscape Workshops, and Design Services	No
1	Provide Rebates for Turf Replacement		Turf Replacement Program	No
2	Expand Public Information Campaign	Minimum 6-15% of water use	Ramp up outreach messaging to emphasize importance of taking action. Continue targeting high water waste potential customers	No
2	Provide Rebates on Plumbing Fixtures and Devices		Implement direct installation programs	No
2	Provide Rebates for Landscape Irrigation Efficiency		Expand Landscape Design Services; offer more frequent landscape workshops and home surveys	No
2	Provide Rebates for Landscape Irrigation Efficiency		Continue Turf Replacement Program and consider increased funding	No

Shortage Level	Demand Reduction Actions	How much is this going to reduce the shortage gap? *Include volume units used.*	Additional Explanation or Reference *(optional)*	Penalty, Charge, or Other Enforcement?
3	Expand Public Information Campaign	Minimum 16-25% of water use	Continue to expand outreach and marketing efforts to mid-tier water waste potential customers	No
3	Provide Rebates on Plumbing Fixtures and Devices		Continue base programs; Consider increase incentive amounts for certain programs; continue smart irrigation direct installation programs	No
3	Provide Rebates for Landscape Irrigation Efficiency		Continue Stage 2 Actions	No
3	Provide Rebates for Turf Replacement		Consider increase incentive amounts	No
4, 5	Expand Public Information Campaign	Minimum 24-50% of water use	Strengthen message of urgency and community call to action	No
4, 5	Provide Rebates on Plumbing Fixtures and Devices		Continue exploring incentive increase and smart irrigation direct installation programs	No
4, 5	Provide Rebates for Landscape Irrigation Efficiency		Continue Stage 2 Actions	No
4, 5	Provide Rebates for Turf Replacement		Consider increase incentive amounts	No

Shortage Level	Demand Reduction Actions	How much is this going to reduce the shortage gap? *Include volume units used.*	Additional Explanation or Reference *(optional)*	Penalty, Charge, or Other Enforcement?
6	Expand Public Information Campaign	Minimum 50% of water use	Implement catastrophic messaging, explore essential use only	No
6	Provide Rebates on Plumbing Fixtures and Devices		Continue exploring incentive increase and smart irrigation direct installation programs.	No
6	Provide Rebates for Landscape Irrigation Efficiency		Consider modifying or suspending programs to support other efforts	No
6	Provide Rebates for Turf Replacement		Consider modifying or suspending programs to support other efforts	No

Note: Each IEUA retail agency has local authority to enforce local water waste ordinances; details of the restrictions by agency can be found in the 2020 DCP and each individual retail agency's 2020 WSCP. Additional details on drought response actions can be found in the IEUA's 2020 DCP and WSCP.

5.3 Supply Augmentation Actions

While IEUA and its retail agencies recognize the need for additional supply during drought years, as a wholesaler, IEUA is limited in its ability to implement water supply augmentation actions. The applicable DWR supply augmentation actions that may be available to IEUA during a water shortage condition are presented in Table 5-2.

Table 5-2: Supply Augmentation and Other Actions (DWR Table 8-3)

Shortage Level	Supply Augmentation Methods and Other Actions by Water Supplier	How much is this going to reduce the shortage gap? *Include volume units used.*	Additional Explanation or Reference *(optional)*
1 through 6	Other actions (describe)	Undetermined amount	IEUA is always exploring opportunities for supplemental recycled water connections and conjunctive use to increase supply and flexibility.
6	Other purchases	Up to 23,531AFY (MWD Contract Amount)	Difference between Resolution No. 2014-12-1 imported amount of 69,752 AFY and MWD tier 1 imported water annual maximum of 93,283 AFY

Note:.

The supply augmentation actions overlap other long-term regional supply reliability activities identified in the IRP as described below; it should be noted that not all IRP activities address a specific water shortage condition in the region.

Additional stored water, in the form of new groundwater production facilities, Chino Desalters with new water transmission lines, pumping plants, and storage tanks significantly increase local supplies and reliability to meet shortages and emergency outages by individual agencies. Interconnections between utilities also allow for mutual supply arrangements and enhances local reliability.

Additionally, through the existing and ongoing regional plans, such as the IRP, there has been considerable effort and extensive stakeholder engagement aimed specifically at developing mitigation-type actions to improve regional water supply reliability.

The mitigation actions identified through the IRP fall into two core strategies.

1. **Invest in Cost-Effective Local Supplies**: As the availability of imported water potentially becomes less reliable in the future, it will be ever more important to continue to invest in cost-effective forms of local water supplies, including groundwater, surface water, and recycled water and conjunctive management of all supplies. It should be noted that MWD is considering investments in new supply projects, both in and out of region. As such, analysis should be undertaken to find the balance of supply-reliability being developed by MWD, IEUA and its retail agencies in any given moment. Building the right amount of local water supply capacity decreases reliance on imported supplies and improves resiliency for the regional water supply portfolio.

2. **Enhance Groundwater Availability**: Groundwater is the most heavily relied on local water supply type. The Chino Groundwater Basin provided approximately 40% of the regional water supply portfolio over the last decade. The vulnerability assessment for the DCP illustrated how compromised groundwater quality poses a significant threat to local water supply reliability and can be compounded as other supplies currently used for blending, such as imported water, become less reliable. Enhancing groundwater treatment and groundwater recharge opportunities will be crucial as groundwater quality issues mount within the basin and dependence on groundwater potentially increases as other sources become less reliable. Groundwater recharge with good quality water sources provides the benefits of both groundwater quality management and increased groundwater storage.

5.4 Prohibitions, Penalties, and Consumption Reduction Methods

This section describes several prohibitions, penalties, and consumption reduction methods including drought ordinances and restrictions.

5.4.1 Emergency Drought Ordinances within IEUA Service Area

IEUA does not have its own drought ordinances concerning drought measures. However, IEUA's retail agencies have several ordinances and measures in place concerning water waste, conservation efforts, and more. Table 5-3 from the DCP lists several ordinances for IEUA's retail agencies.

Table 5-3: Water Waste Ordinance by Agency (IEUA 2020)

Agency	Ordinance/Code Title
City of Chino	Municipal Code Water Conservation 13.-5.010 – 13.05.120
City of Chino Hills	Ordinance 300u
Cucamonga Valley Water District	Ordinance 2019-5-1
Fontana Water Company	San Gabriel Valley Water Company Rule No. 14 & Schedule 14.1
Monte Vista Water District	Ordinance 33
City of Ontario	Municipal Code Water Conservation Plan Title 6, Section 8A
City of Upland	Municipal Code 13.16.020 & 13.16.05.050

5.4.2 Voluntary and Mandatory Restrictions

Both voluntary and mandatory restrictions are coupled with public education campaigns to provide customers with information about the purpose for the restriction(s) and the call-to-action. Restrictions are typically highly publicized through local media, web pages, social media, mailings, and water bills.

Mandatory restrictions are a more effective tool for drought coping than voluntary measures; however, mandatory restrictions may create heightened negativity directed at the customer's water provider.

Common restrictions include partial or total prohibitions against using hoses to wash paved areas, limits on car washing and filling or refilling swimming pools, and restrictions on watering times.

As drought stages are declared, each agency will implement voluntary and mandatory restrictions as dictated by their respective Water Waste Ordinance. It is important to note the following:

1. Each ordinance is unique to a specific water provider and the ordinances differ slightly from one another.

2. Ordinance stages are locally declared and therefore, may not align with other agencies or a regionally declared stage.

Although enforcement is difficult to maintain, each agency is responsible for locally enforcing each ordinance. In order to accomplish this, agencies must add field staffing, coordinate with administration of the water waste ordinance, and manage the increased level of customer phone calls.

Enforcement has been critical to the integrity of the ordinance in the past and remains critical for future water shortages as well. Without action and penalties, the ordinance will not be taken seriously by customers, which then nullifies the effectiveness of the initiative. Typically, violations are reported by community members or visually seen by agency staff. Enforcement staff will then send letters, visit customer properties, and educate customers on the importance of adherence for both the resident and the overall community.

5.5 Operational Changes

IEUA does not operate any imported water systems and therefore, does not require operational changes during a water shortage. Changes to supply augmentation are described in Section 5.3 and consumption reduction methods are described in Section 5.4.

5.6 Customer Compliance, Enforcement and Appeal, and Exemption Procedures for Triggered Response Actions

IEUA does not have direct retail customers. However, IEUA is part of the Drought Response Taskforce (described in Section 5.7.2), which supports retail agencies with various resources for coordination, outreach, enforcement and more. The Taskforce coordinates with retail agencies and staff to identify resource and funding needs. Further explanation of the current funds and the funding process is described in the Regional Water Use Efficiency Business Plan (IEUA 2019).

5.7 Description of Legal Authorities to Implement and Enforce Shortage Response Actions

This section describes the legal authorities that implement and enforce shortage response actions, including their roles and responsibilities. Additionally, mutual aid agreements are described.

5.7.1 Roles and Responsibilities

IEUA: IEUA serves as the administrative facilitator of all components of the DCP. IEUA is responsible for developing regional demand and supply projections, calculating supply/demand ratio, communicating outcomes, convening the Drought Response Taskforce, implementing response strategies and actions as determined by the Drought Response Taskforce, conducting vulnerability assessments, evaluating and implementing IEUA controlled mitigation actions, and updating the plan.

Retail Agencies: Retail agencies are responsible for providing demand and supply projections, implementing agency-selected local mitigation actions, participating on the Drought Taskforce, and implementing response actions including local water waste restrictions.

5.7.2 Drought Response Taskforce Process

Once the drought monitoring framework indicates that the region has reached a specific stage of drought conditions, several actions will occur.

First, the Drought Response Taskforce (Taskforce) will assemble. The Drought Response Taskforce is the organizational group empowered to:

1. Create the Drought Response Plan blueprint.
2. Assemble the Taskforce to finalize strategic response actions during drought condition stages.
3. Work with their respective organization to implement response actions, according to plan.

The Taskforce is comprised of representatives from each of the retail agencies, in addition to personnel from IEUA. The group works in a collaborative effort to gain consensus on appropriate regional response actions.

The Taskforce will make decisions about the level of programming and services, restrictions, and messaging to regional customers. Additionally, the group determines the level taken for each element of the plan.

It is important to note that during a regional drought, an individual retail agency may not be experiencing a drought condition due to their local supply mix. In this circumstance, the agency may elect the capacity in which to participate on the Taskforce. The agency may determine how best to communicate with its customers when there are no water supply issues, locally while the region is undergoing a drought stage.

Moving forward, the Taskforce will work to balance the effectiveness of regional messaging with the differing needs of individual retail agencies. There are no pre-determined mandates regarding service offerings, restrictions, communications, or budgets. The Taskforce will collaborate on policies, while fully supporting flexibility for each agency.

The group will review the proposed actions set forth in the existing plan and make modifications, as necessary. The plan was intended to be flexible and changeable. Modifications to the plan might include a change in incentive levels or program delivery mechanisms. There may also be a new water-saving technology that may be available to customers. The Taskforce may be able to secure additional grant funds, as well. Once the action plan is finalized, the Taskforce will implement the programs, penalties, and communications plan, as agreed upon.

An overview of the DCP drought response process is provided on Figure 5-1.

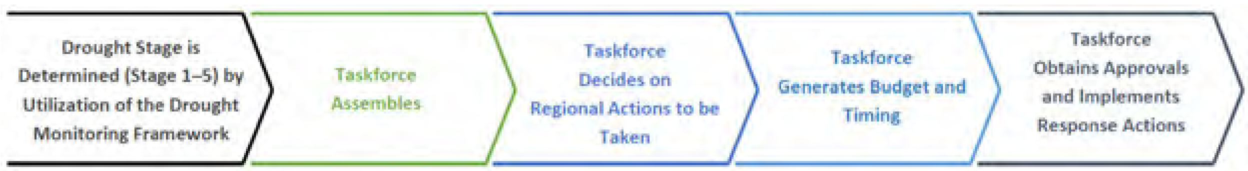

Figure 5-1 Drought DCP Response Process

5.7.3 Mutual Aid Agreements

IEUA currently has no mutual agreements except those concerning the sanitary sewer system. Additionally, retail agencies typically coordinate with other agencies to balance water uses.

5.8 Effectiveness of Shortage Response Actions (by Water Shortage Stage)

This section describes the annual review of the shortage response actions outlined in Section 5.1. Additional reviews for effectiveness are outlined in the WUE Business Plan (IEUA 2020), which is updated every 5 years.

The Drought Response Taskforce process described in Section 5.7.2 resulted in several programs that would address water shortages. The following process was used to determine the effectiveness of each program. It is important to note that the ranking process provides general consensus and structure for planning, but program ranking is fluid and, as circumstances evolve in the future, selected programs and priority levels may change.

1. Each of the selected programs addressing water shortages were ranked by agency representatives to determine its viability during each advancing drought stage. The selection process for these programs and services was conducted by having agency representatives individually rank viable programs as a high (3 points), medium (2 points), or low (1 point) at each respective drought stage level.

2. This ranking criterion was based on the level of feasibility, appropriateness, and overall impact provided by that program/service at each drought stage. Budgets and program scalability were additional considerations factored into the ranking process. The group also assessed the effect and motivation that escalating drought stages would have on customers and how that, in turn, might drive customers' response for each program/service.

3. The results were totaled and averaged for each program/service at each drought stage. Higher numbers reflected a greater expected effectiveness for that program or service. Lower numbers indicated reduced support for the program or service and less likelihood for inclusion in the list of program offerings.

4. Using the high, medium, or low point rubric program rankings were compiled and recorded.

In general, it was found that the higher the drought stage, the more program services were to be provided by agencies. It was also found that there is heightened customer response and program participation during higher drought stages. This is especially true when customers are provided with free installation and low-cost product or, as with turf incentives, the rebate level is enticingly high. Additionally, as stages escalate, agencies are prepared to ramp up activity for all programs, but will rely most heavily on Turf Replacement, FreeSprinklerNozzles.com, and direct installation of landscape measures. The number of home surveys, workshops, and design services may also increase. Home Leak Detection was ranked as the lowest priority program during Stage 0 and Stage 1, and only ramps up significantly in the later drought stages.

At each drought stage, it is anticipated that the highest-ranking programs will be those most actively promoted, and those offering attractive customer enticements to participate.

However, it is important to reinforce that the program and services rankings are not absolute and are a suggested template to be adjusted according to circumstances that exist at each actual drought stage. Actual incentives, services, and roll out schedules will be determined by the Taskforce when the drought stage is declared and the group is assembled.

Section 6: Communication Protocols

This section describes communication protocols as outlined in the 2020 DCP.

6.1 Messaging and Outreach

Communication and outreach play as crucial a role in the delivery of water savings as the programs themselves. A strong plan will ensure that IEUA reaches the target audience, boosts awareness, and ultimately, delivers water savings. For this reason, the Response Plan communication must:

- Be heard by the right customers, understood, and favorably received.
- Clearly inform the customer of the current stage, tell them what action is desired, and motivate them to respond to the request.

Ultimately, all forms of communications and outreach must work together throughout the region to raise response and increase water savings per household. The combination of regional drought messaging paired with the retail agencies' individual outreach efforts will create a stronger, more unified message.

6.2 Requirements for An Effective Message and Campaign

The key principles of a successful outreach and communication campaign are:

1. Know Your Customer.
2. Get the Message Right.
3. Craft an Outreach Plan that Drives Customer Response.

6.2.1 Know Your Customer

An organization must understand each customer's needs in order to provide the "I can't say no" offer. Companies experience much higher response rates when they understand and effectively respond to customers' needs.

Target audiences are single family households with high water-use and large landscape customers. Reaching these customers requires data analysis, creation of customer personas, and micro-targeting. There are numerous analytics programs available today that help agencies identify distinct customer groups and personas. Statistics show that micro-targeting greatly boosts customer response, which in turns leads to higher water savings as well.

6.2.2 Get the Messaging Right

Marketing campaigns are highly successful when they evoke emotion and resonate with a human need. An emotional message strategy uses feeling, which is a much more powerful motivator than logic, to sell. An outreach vehicle using this tactic will make the target audience feel an emotional connection to the agency, program, water efficiency measure, and/or call-to-action. IEUA will need to utilize the following messaging strategies to garner interest and participation from customers:

- **Emphasize the benefits**: What does this specific customer need? Present a solution to their problem.
- **Keep it simple**: A confused mind says “no.” People worry that deceit is hidden amongst complexity.
- **Make it Fun**: Draw customers in by using fun and catchy messaging, stories, eye-catching visuals, and humor.
- **Use Authority**: Influencing others is easier if customers view the person making the pitch as an authority figure. We all like to listen to and follow an expert. We trust that they know what they are doing.

6.2.3 Two Types of Messaging Required

There are reasons for creating and driving mass audiences through broad messaging as opposed to targeted action messaging directed to specific audiences. IEUA will need to effectively provide both types of communication during drought conditions.

1. **Broad Messaging:** Broad messaging (delivered via news stories, radio/TV ads, billboards, etc.) provides the widest reach and allows IEUA to communicate overarching messages including:
   a. Water Scarcity Issue
   b. Urgency to Act
   c. Commitment to continue to provide safe, reliable water supply.
2. **Targeted Action Messaging:** Targeted action messaging is typically aimed at specific groups of customers (i.e., those most likely to respond to your request for program participation or water-use reduction). To promote action, IEUA and the retail agencies must create messaging content and outreach such as those described below.
   a. Design messaging to motivate landscape changes for single family customers
   b. Post success stories: community members, people of prominence, business leaders
   c. Promote stories from micro-influencers: Q&A blogs with customers, homeowner success stories, “Did You Know?” educational snippets

d. Consider the utilization of third-party influencers: these individuals are more trusted than a company itself

e. Create a community call to action: “your community needs your help” messaging.

6.2.4 Craft an Outreach Plan that Drives Customer Response

Successful outreach campaigns utilize the following strategies:

- Profile your customers to understand customer’s persona
- Micro-target to prospect the right customers for each offer
- Incorporate your strong messaging and influencer authority figures in all offers
- Add personalization
- Demonstrate value and generous offer
- Include a call to action
- Make it easy for customers to say “YES”
- Follow up
- Track results
- As stages advance, increase frequency, urgency, and intensity.

IEUA and its retail agencies will need a creative and dynamic approach in order to increase customer response and water use reduction, especially during higher drought stages.

6.3 Successful Outreach Methods

There are major outreach mechanisms to be utilized for general categories of customers. Each outreach approach should be personalized to the group being targeted, as follows:

- Direct outreach to high users via personalized means (phone, letter, email, etc.)
- Regional outreach through broad media channels
- Earned media
- Social media
- Grassroots and community outreach.

6.4 Importance of Influencers and Relationships

Influencer marketing is another effective strategy to enhance response. Influencers are trusted individuals who have a large audience and can reach across media and social platforms. Because of their high level of “trust-ability”, they’re often able to persuade (or “influence”) readers and viewers to purchase products or endorse causes that they promote.

Influencer marketing is a highly effective way to reach interested customers and dramatically increase response. They act as a trusted and respected “friend”, as customers trust third party influencers more than a company itself. Those prominent in the Inland Empire include:

- Well known business owners/leaders
- Local sports or entertainment figures
- Elected officials
- Active Parent Teacher Association members
- High profile community organizers.

6.5 Drought Outreach Matrix

The urgency for communications increases as drought stages escalate. Because customers are essential to water-savings solutions, it is imperative that they understand each drought stage and what is required of them. Quality messaging will clearly communicate the current drought stage, define the condition, request a desired customer behavior, and direct them to tangible solutions. Table 6-1 shows the DCP drought outreach matrix for IEUA, which outlines the possible outreach methods for each water shortage stage.

Table 6-1: DCP Drought Outreach Matrix for IEUA

Stages	0	1	2	3	4	5
Messaging	Overall preparedness and drought resiliency. Drought will be regular occurrence.	What ***Watch*** Condition Means	What ***Warning*** Condition Means	What ***Emergency*** Condition Means	What ***Critical*** Condition Means	What ***Catastrophic*** Condition Means
Desired Behavior	Get customers to install drought resilient landscapes & smart irrigation prior to the next drought.	Minimum 1-5% decrease in water use.	Minimum 6-15% decrease in water use.	Minimum 16-25% decrease in water use.	Minimum 25-50% decrease in water use.	Water used for only essential functions.
Outreach Strategies	Evaluate your specific community and the customers in your service territory to determine a compressive plan using a combination of the following strategies and tactics. Each approach should be personalized to the group you are targeting. - Direct outreach to high users - Regional outreach through broad media channels - Social media outreach - Grassroots and community outreach					

Section 7: Mechanism to Determine Reductions in Water Use and to Meet State Reporting Requirements

Water Code Section 10632(a)(9) is not applicable for IEUA, as it is a requirement for urban retail water suppliers. However, the IEUA WUE Business Plan addresses methodologies for and the effectiveness of attaining water use efficiency. The IEUA WUE Business Plan is a working document and, as such, must be modified and updated as changes occur, and program years roll out. IEUA regularly reviews the plan and makes adjustments accordingly.

Changes and/or reviews of the plan take place in line with the following conditions:

- When programs are added, subtracted, or modified.
- On a yearly basis in order to meet the annual reporting requirements.
- Every 5 years to meet the Urban Water Management Plan report cycle.
- As the State's Framework policies are finalized.

Section 8: Impacts to Revenue

This section addresses Water Code Section 10632(a)(8).

If a drought is declared, financial impacts to the local retail water agencies will vary from one agency to another. As a wholesale water agency, IEUA is simply a “pass-through” wholesaler, so loss of revenue has no significant impacts. One exception may include the loss of revenue due to conservation programs that receive a portion of funding through a surcharge on each acre-foot of imported water sold. Otherwise, IEUA’s revenue is no longer based on water sales. Revenue is currently based on the number of meters as well as meter size within its area.

Current rates are outlined in Resolution No. 2019-6-1.

Section 9: Actions to Prepare for Catastrophic Supply Interruption

This section largely relies on the analyses performed in previous UWMPs and meets Water Code Section 10632(a)(3).

9.1 Planning for a Catastrophe

Southern California's three imported water supplies (State Water Project, Colorado River Aqueduct, and Los Angeles Aqueduct) cross the San Andreas Fault. Many other fault lines bisect major water facilities throughout the region. Experts consider it likely that one or more of these supplies will be disrupted in the event of a major earthquake. Given the great distances that imported supplies travel to reach the Inland Empire, the region is vulnerable to imported water interruptions along hundreds of miles of aqueducts, pipelines and other facilities associated with delivering the supplies to the region.

MWD has comprehensive plans for stages of actions it would undertake to address a catastrophic interruption in water supplies through its WSDM and WSAP. MWD also developed an Emergency Storage Requirement to mitigate against potential interruption in water supplies resulting from catastrophic occurrences within the southern California region, including seismic events along the San Andreas Fault. For MWD, the required planning is captured in its Emergency Storage Objective, Seismic Resiliency Reports, and Emergency Response Plans. For greater detail on MWD's planned responses to catastrophic interruption, please refer to MWDs 2020 UWMP.

MWD estimates that restoring service on any of these facilities following a catastrophic outage could take up to 6 months. This, in turn, could reduce annual deliveries by roughly up to 50% for MWD-supplied water. The UWMP requires agencies to consider the effect of a 50% cutback in water supplies. This corresponds approximately to the degree of cutback contemplated by MWD's earthquake disruption scenario.

IEUA is unique among MWD member agencies in that it only has access to imported water off the eastern branch of the State Water Project and does not have access to most of MWD's in-region surface storage supplies. Therefore, a catastrophic interruption of SWP supplies would be particularly impactful on IEUA.

In September 2005, IEUA adopted federal emergency response procedures called NIMS (National Incident Management System) which can be implemented by IEUA personnel for a localized event such as an accident at one of IEUA's facilities or on a broader based regional event such as an earthquake or flood. This system provides a consistent nationwide template to enable federal, state, and local governments (and local private sector and non-governmental organizations) to work together effectively and efficiently to prepare for, prevent, respond to, and recover from domestic incidents, regardless of cause, size, or complexity, including acts of terrorism. Complementary to NIMS, IEUA has completed Mutual Aid Agreements between itself and its local retail agencies (see Appendix R of 2010 UWMP).

9.2 Supply Augmentation Actions

The methods described in Section 5.3 will apply during emergencies.

9.3 Emergency Curtailment of Imported Water

In June 2004, MWD conducted an unplanned shutdown of the Rialto Feeder pipeline. The pipeline was discovered to be in danger of collapse and repairs were needed immediately. Because the Rialto Feeder is the only source of significant imported water deliveries to the IEUA and the Three Valleys Municipal Water District (TVMWD) service areas, the loss of that supply during the summer when municipal and industrial water demand was high, could have had a devastating impact on local agencies. The Rialto Pipeline Shutdown occurred from Monday, June 7, 2004 through Saturday, June 12, 2004.

To prepare their customers for the shutdown, the local agencies coordinated among themselves, MWD, and the local television and newspaper media. Water agencies asked their largest customers to stop irrigating their landscapes and stop all non-essential water uses during the 5-day shutdown for repairs. Also, local agencies asked their residential customers to eliminate landscape irrigation and to reduce or eliminate their non-essential water use practices. Because each local agency has a different resource mix, each agency was affected somewhat differently by the shutdown. Some retail agencies rely on imported water to supply a large portion (as much as 50%) of their demand during that time of the year.

One retail agency determined that the best course of action was to declare a “state of water supply emergency” and issued an emergency shutdown notice to all their customers. Their customers responded well to the request by reducing overall water use by 60% during the repairs. This response allowed CVWD to successfully meet all essential municipal and industrial demands, as well as fire flow requirements. Other local agencies saw similar responses from their customers.

In the weeks following the shutdown, MWD, IEUA, and TVMWD issued a survey questionnaire to the affected water agencies asking for their assessment of the way the shutdown was handled.

The responses to the survey showed, that overall, the lead agencies response to the shutdown and coordination with local media were reasonably successful. There was some confusion by commercial and residential properties owners on how to operate their irrigation controllers. As a result, a few landscapes remained watered during the first days of the shutdown. There was also some confusion by the public as to why several large landscapes in certain cities were being watered. As it turned out, these sites were using recycled water to irrigate. Ultimately, the irrigation was turned off to avoid further confusion.

Each of the agencies learned valuable lessons during this water emergency. Clearly, when the public is informed about the issue, water supply officials can expect a generally positive response from the public. The coordination with local agencies, the distribution of information, and conservation suggestions to the residents are the keys to maintaining credibility and confidence with the public.

MWD has initiated a program to rehabilitate 100 miles of pre-stressed concrete cylinder pipe (PCCP) on five at-risk major feeders with ongoing monitoring, evaluation, and prioritization for immediate repair and rehabilitation over 20 years. MWD is closely coordinating with IEUA and its retail agencies to help mitigate immediate emergency concerns on the Rialto Pipeline by continuing regular inspection and monitoring for stray currents and/or installation of cathodic protection and performing individual segment repairs as needed. MWD has also developed an extensive rehabilitation effort expected to cost over $600 million for the Rialto Pipeline alone that is in its early stages of planning and design.

Section 10: Reevaluation and Improvement Procedures

The WSCP is founded on several planning documents including the IEUA WUE Business Plan. The IEUA WUE Business Plan outlines methodologies and sets goals that measure the effectiveness of water use efficiency programming. The IEUA WUE Business Plan is a working document and, as such, must be modified and updated as changes occur and program years roll out. IEUA reviews the plan every 5 years in conjunction with the UWMP and adjusts accordingly. The WSCP will also be evaluated and updated on the same 5-year cycle.

IEUA is in the process of updating the 2015-2020 Water Use Efficiency Business Plan. The State is tentatively scheduled to finalize the new water use efficiency standard/objective and establish water use objectives for Retailers by 2023. IEUA's WUE Business Plan is being completed in two phases. Phase I will cover FY 2021-2023 and incorporate existing and newly proposed programs and measures. Phase II will cover FY 2023-2025, expand on Phase I existing and new programming, and develop a pathway to meet or exceed compliance with the new State regulations.

Section 11: Water Shortage Contingency Plan – Adoption Resolution

11.1 Overview

During the process of preparation of the UWMP, IEUA also reviewed related information from regional and local agencies and developed this WSCP, which was largely founded on the 2020 DCP. An extensive coordination effort occurred during the DCP preparation between September 2017 to September 2019 which included five workshops, as well as four Response Action Taskforce meetings. IEUA also encouraged public involvement in the UWMP and WSCP by holding a public hearing for residents to learn and ask questions about their water supply.

This section provides the information required in Water Code Section 10632(a)(c) related to adoption and implementation of the WSCP. Table 11-1 summarizes external coordination and outreach activities carried out by the IEUA and the corresponding dates.

Table 11-1: External Coordination and Outreach

External Coordination and Outreach	Date	Reference
Notification of Preparation; Encouraged public involvement	November 24 and 30, 2020	WSCP Appendix B
Notified city or county within supplier's service area that water supplier is preparing an updated UWMP (at least 60 days prior to public hearing)	April 5, 2021	WSCP Appendix C
Newspaper notice of public hearing and intent to adopt UWMP and WSCP	May 17 and May 24, 2021	WSCP Appendix D
Adopted UWMP and WSCP by Resolution	June 16, 2021	WSCP Appendix E
Submitted UWMP and WSCP to DWR (no later than 30 days after adoption)	By July 1, 2021	-
Made UWMP and WSCP available for public review (no later than 30 days after filing with DWR)	By July 1, 2021	-
Submitted UWMP and WSCP to the California State Library and city or county within the supplier's service area (no later than 30 days after adoption)	By July 13, 2021	-

The UWMP and WSCP was adopted by IEUA's Board of Directors on June 16, 2021. A copy of the adopted resolution is provided in WSCP Appendix E.

IEUA also notified any city or county within its service area at least 60 days prior to the public hearing. As indicated in Table 11-2, IEUA sent a Letter of Notification to the County of San Bernardino and cities within its service area in November 2020 and again in April 2021 to state that it was in the process of preparation to meet the DWR requirements (WSCP Appendices A and B).

Table 11-2:Notification to Cities and Counties (DWR Table 10-1)

☑	Supplier has notified more than 10 cities or counties in accordance with Water Code Sections 10621 (b) and 10642. **Completion of the table below is not required. Provide a separate list of the cities and counties that were notified.**	
Table 11-2 of the WSCP	Provide the page or location of this list in the UWMP.	
	Supplier has notified 10 or fewer cities or counties. **Complete the table below.**	
City Name	**60 Day Notice**	**Notice of Public Hearing**
Add additional rows as needed		
City of Chino	☑	☑
City of Chino Hills	☑	☑
Cucamonga Valley Water District	☑	☑
Fontana Water Company	☑	☑
Monte Vista Water District	☑	☑
City of Ontario	☑	☑
San Antonio Water Company	☑	☑
City of Upland	☑	☑
City of Rancho Cucamonga	☑	☑
City of Montclair	☑	☑
West Valley Water District	☑	☑
County Name	**60-Day Notice**	**Notice of Public Hearing**
Add additional rows as needed		
San Bernardino County	☑	☑

Notes: In addition, the following agencies were also given a 60-Day Notice and Notice of Public Hearing: Chino Basin Water Master, Chino Basin Desalter Authority, Local Agency Formation Commission for San Bernardino County, Metropolitan Water District, Santa Ana Regional Water Quality Control Board, Santa Ana Watershed Project Authority, Three Valleys Municipal Water District, and the Water Facilities Authority.
Notification letters were sent out in November 2020 and April 2021. Copies of these notification letters are included in WSCP Appendices A and B.

11.2 Public Participation

IEUA encouraged community and public interest involvement in the plan update through a public hearing and inspection of the draft document on June 16, 2021. Public hearing notifications were published in local newspapers. A copy of the published Notice of Public Hearing is included in WSCP Appendix D. The hearing provided an opportunity for all residents and employees in the service area to learn and ask questions about their water supply in addition to the IEUA's plans for providing a reliable, safe, high-quality water supply. Copies of the draft plan were made available for public inspection at the IEUA headquarters and website.

11.3 Agency Coordination

IEUA's water supply planning relates to the policies, rules, and regulations of its regional and local water providers. IEUA is dependent on imported water from MWD, its regional wholesaler. As such, IEUA involved the water providers in this 2020 UWMP at various levels of contribution as summarized in Table 11-3.

11.4 WSCP Submittal

IEUA's five-member Board of Directors reviewed and approved the Final 2020 WSCP on June 16, 2021 (Resolution No. 2021-06-10). See WSCP Appendix E for the resolution approving the Plan.

By July 1, 2021, the adopted 2020 WSCP was filed with DWR and posted to IEUA's website. By July 13, 2021, the adopted 2020 WSCP was filed with the California State Library, County of San Bernardino, and cities within its service area, if applicable.

Table 11-3: Coordination with Appropriate Agencies

Agency Name	Participated in Plan Development	Commented on Draft	Attended Public Meetings	Sent Notice of Plan in Preparation[a]	Received Copy of Draft Plan[b]	Sent Notice of Intent to Adopt[a]	Received Copy of Adopted Plan[b]
City of Chino	No	No	No	Yes	Yes	Yes	Yes

Water Facilities Authority	No	No	No	Yes	Yes	Yes	Yes

Notes:

(a) IEUA sent notice of plan in preparation in November of 2020 and notice of intent to adopt in April 2021. Both notices are included in WSCP Appendices A and B.
(b) IEUA posted the draft 2020 WSCP to its website on 11 May 2021 and the adopted final 2020 WSCP to its website prior to July 1, 2021.
(c) While stakeholders did not participate directly in the development of the WSCP, stakeholders participated in the development of the foundational 2020 DCP, provided supply and demand data, and/or provided input to the Draft 2020 Water Use Efficiency Business Plan.

IEUA is a wholesale distributor of imported water and a regional wastewater treatment agency, serving 875,000 residents over 242 square miles.

As a public agency, IEUA purchases imported water from the MWD Water District of Southern California (MWD) and is situated on the largest groundwater storage basin in Southern California.

IEUA wholesales water purchased from Metropolitan Water District of Southern California (MWD) to cities, municipal water districts, investor-owned utilities and special districts. IEUA's retail agencies include: the cities of Chino, Chino Hills, Ontario, and Upland, Cucamonga Valley Water District in the city of Rancho Cucamonga, the Fontana Water Company in the city of Fontana, Monte Vista Water District in the city of Montclair, and San Antonio Water Company in the city of Upland.

What Defines a Drought?

A *drought* is a natural prolonged period of abnormally low rainfall, leading to a shortage of water. Drought is a weather-related recurring feature in Southern California and the Inland Empire region.

While drought cannot be prevented by local water management, the impacts can be mitigated by preparing the region for the eventuality of a future drought cycle.

What Defines a Water Shortage?

A *water shortage* is the lack of sufficient available water resources to meet the demands of water usage within a region, either for a short-term or long-term duration. The shortage can be caused by a variety of reasons including groundwater contamination or other water quality constraints.

While noting the distinction between drought and water shortage, both of these conditions are impactful. The Inland Empire may find that there is a situation wherein there isn't a drought, but instead, a groundwater quality issue, causing a shortage that impacts the entire area.

IEUA and its member agencies are acutely cognizant that preparedness for either occurrence is critical to the region.

1 Introduction

A Look Back

IEUA created the 2009 Drought Plan at the time when the region was in the midst of a prolonged three-year drought. The main objective of the plan was to implement Metropolitan Water District's Water Supply Allocation Plan. This well-reasoned plan provided a fair and equitable process for allocating potential future limited water supplies.

Two years later, IEUA and its member agencies faced one of the most intense droughts in California history (2011 – 2017); with the period of late 2011 through 2014 being the driest in California's recorded history.

Gaining Insight

With tremendous collective efforts on the part of IEUA and retail member agencies, the region endured the demanding years of these drought cycles. Despite the many dead lawns and unwashed cars, thanks to regional and local response actions, adequate supply was never a question.

The numerous challenges that arose during this time period yielded much gained insight for water resource managers throughout the State.

It was clear that the great majority of customer sites were not drought resilient going in, or coming out, of the drought. Water savings came about predominantly through restrictions; not customer drought preparedness.

Breaking from this trend, customers in the IEUA service area did respond to the turf removal program; removing over 7 million square feet of turf AND customers rallied and reduced water usage by over 30%. While this occurred rather late in the drought cycle, the focus on long term drought preparedness was a welcomed sight.

The 2011 – 2017 drought illustrated the growing evidence that climate change is causing longer and more frequent droughts. The 2009 Drought Plan, while appropriate for its time, needed to be expanded.

USBR Grant Funding

Coinciding with the need for a more robust plan, the United States Bureau of Reclamation (USBR) provided a funding opportunity for development of Drought Contingency Plans (DCP), with the aim of building long-term resiliency to drought and climate change.

In 2016, IEUA submitted a proposal and received grant award for development of a DCP. The objectives of the planning process, as put forth by USBR, were to help resource planners to 1) recognize drought in its early stages; 2) identify the effects of drought or water shortages; and 3) provide water supply protection into the future.

As required under this grant, IEUA has documented the input and participation of our multiple stakeholders, factored climate change impacts to drought conditions, and identified potential drought mitigation and response actions, to enhance the IEUA region's resilience to drought, as exacerbated by climate change.

The DCP, as a federally sanctioned plan, not only provides the IEUA region with an increased level of proactivity and preparedness, it also better positions IEUA and its member agencies, should there be a need for federal emergency relief funds.

Goals of the Drought Contingency Plan

The DCP is a comprehensive plan, designed to:

- ✓ **Define regional shortage conditions** to tailored stages, responses, and mitigation actions for the IEUA service area needs and resources.
- ✓ **Build resiliency** by identifying and facilitating investment in local projects that strengthen and further diversify water portfolios within the service area (i.e. conservation, recycled water, interconnections, and groundwater recharge).
- ✓ **Facilitate consistent communication** for the service area to ensure consistency and effectiveness during times requiring reduced water usage.
- ✓ Maintain a commitment to **sustainability and environmental stewardship** by meeting the needs of the present without compromising the ability of future generations to meet their own needs.
- ✓ **Maintain consistency** with Metropolitan Water District's Water Shortage Allocation Plan and Dry Year Yield policies, as well as other IEUA and member agency water resource planning documents.
- ✓ Ensure **equity and fairness** throughout the service area.

Plan Components

There are five distinct components to IEUA's plan, as required by the USBR grant:

1. The Drought Monitoring Framework
2. The Vulnerability Assessment

3. Mitigation Actions
4. Response Actions (Drought Communications & Outreach Plan)
5. The Operational & Administrative Framework

The **Drought Monitoring Framework** provides the tools and data metrics necessary to determine the existence and severity of a drought or water shortage.

The **Vulnerability Assessment** identifies and quantifies the key factors that can negatively affect water supply reliability.

The **Mitigation Actions** are prioritized projects and strategies that can be implemented prior to a drought situation in order to lessen the risks and impacts of water shortages.

The **Response Actions** provide a blueprint for deployment of strategic response actions for each stage of water shortage or drought condition.

The **Operational and Administrative Framework** describes the roles, responsibilities and procedures to implement each element of the Plan.

Plan Development Process

The development of the drought plan was intentionally crafted to be a highly collaborative and inclusive process.

IEUA launched the project by assembling a taskforce, inclusive of each retail agency's management, planning and conservation staff as well as other regional stakeholders.

GEI Consultants, one of nations leading engineering firms with a known capability for drought planning, was awarded the contract to develop the plan.

Periodic taskforce meetings were held to present the outcomes of each planning component. Taskforce members were solicited for feedback, after which final technical memos were produced for:

1) Drought Monitoring
2) Vulnerability Assessment
3) Mitigation Actions

Additionally, consultant Maureen Erbeznik, a conservation program design and implementation expert, was hired to develop the response actions also known as the Communications & Outreach Plan. Four additional stakeholder workshops were convened with IEUA and retail member agency conservation staff. Over the course of the four workshops, the group ranked and selected programs best suited for drought response, established a strategy for restrictions & enforcement, identified communication tactics, and aligned these response actions with drought stages. The Communications & Outreach Plan was then integrated with the technical memos produced by the taskforce to create the final Drought Contingency Plan.

It is important to note that outcomes of the planning process are not a "cast in stone" series of actions that become mandated procedures, requiring stakeholder adherence. Instead the plan results act as a resource and general guide for IEUA and the member agencies. It is understood that each retail agency has its own distinct supply portfolio, operating principals, and customer characteristics. As such, there may be instances when a retail agency is not experiencing the same drought or water shortage impacts and will choose to take a modified course of action.

When the time comes and a regional drought is declared, a Drought Response Taskforce will be assembled with representatives from each agency. This group will review the recommended response actions for that particular drought stage, modify according to the "real life" conditions, set a budget, and finalize the drought response course of action.

Additional Benefits of the Plan

The USBR grant has allowed IEUA and the member agencies to create a plan that will deliver an increased level of proactivity and preparedness in advance of future water shortages. It integrates multiple local drought planning initiatives, tools and resources under one umbrella. At the same time, it increases the speed that drought response actions can be rolled out by providing a more detailed guide.

The plan provides a medium to document and attest to the completeness of drought planning activities. In addition, the plan meets federal and states "checklists" for drought and water shortage contingency planning. The DCP not only meets the requirements for USBR grants, but also directly aligns with the State of California's requirements for a Water Shortage Contingency Plan (WSCP).

In other words, the retail agencies are each required to create a WSCP as part of their Urban Water Management Plans. Should the agencies choose to create, instead, a Regional WSCP, the Drought Contingency Plan provides nearly all of the component requirements of the Regional WSCP.

Table 1 below lists and compares the contents of the DCP with the requirements of the WSCP:

Table 1 . DCP Components Compared to Water Shortage Contingency Plan Requirements

Contents	DCP	WSCP
Analysis of water supply reliability	✓	✓
Written decision making process to determine water supply reliability	✓	✓
Key data inputs and assessment methodology used to evaluate the water supply reliability	✓	✓
Unconstrained demand, considering weather, growth, and other influencing factors	✓	✓
Available supply, considering hydrological and regulatory conditions in the current year and one dry year	✓	✓
Existing infrastructure capabilities and plausible constraints	✓	✓
Evaluation criteria water supply and demand assessment	✓	✓
Description and quantification of each source of water supply	✓	✓
Six standard water shortage levels corresponding to progressive ranges of up to 10, 20, 30, 40, and 50 percent shortages and greater than 50 percent shortage	✓	✓
Water shortage response actions that align with the defined shortage level	✓	✓
Mandatory prohibitions against specific water use practices	✓	✓
Communication protocols and procedures	✓	✓
Description of the financial consequences of, and responses for, drought conditions	--	✓
Mitigation actions needed to address revenue reductions and expense increases	--	✓
Monitoring and reporting requirements and procedures	✓	✓
Monitoring and evaluating the functionality of the water shortage contingency plan to ensure mitigation strategies are implemented as needed	✓	✓

2 Background

2.1 IEUA Service Area

Formed in 1950, Inland Empire Utilities Agency was originally created with a mission to supply supplemental imported water purchased from the Metropolitan Water District of Southern California (MWD) to municipalities in the Chino Groundwater Basin.

Since then, IEUA has expanded its mission and, today is focused on providing the following key areas of service:

- Securing and supplying imported water.
- Collecting and treating wastewater.
- Producing high-quality renewable products such as recycled water, compost, and energy.
- Promoting sustainable use of groundwater and development of local water supplies.

The area is relatively flat alluvial valley from east to west and slopes from north to south at a one to two percent grade. Valley elevation ranges from about 2,000 feet above sea level in the foothills below the San Gabriel Mountains to about 500 feet near Prado Dam.

The IEUA service area almost entirely overlies the Chino Groundwater Basin and covers approximately 242 square miles in western San Bernardino County (see Figure 1).

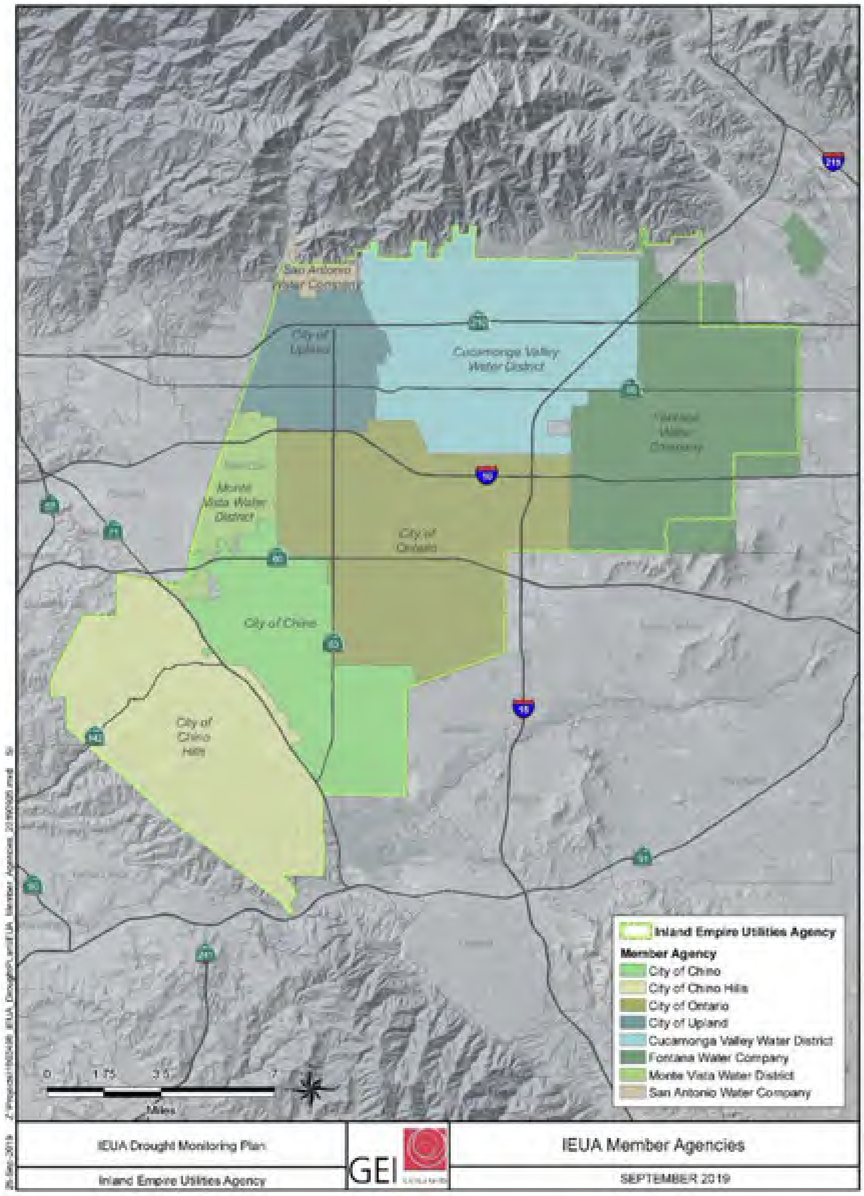

Figure 1. IEUA Service Boundary Map

2.2 CLIMATE

IEUA is located within the South Coast Air Basin (SCAB) that encompasses all of Orange County and the urban areas of Los Angeles, San Bernardino, and Riverside counties. The SCAB climate is characterized as "Mediterranean" with a semi-arid environment and mild winters, warm summers, and moderate rainfall. A summary of the annual precipitation is provided in Figure 2.

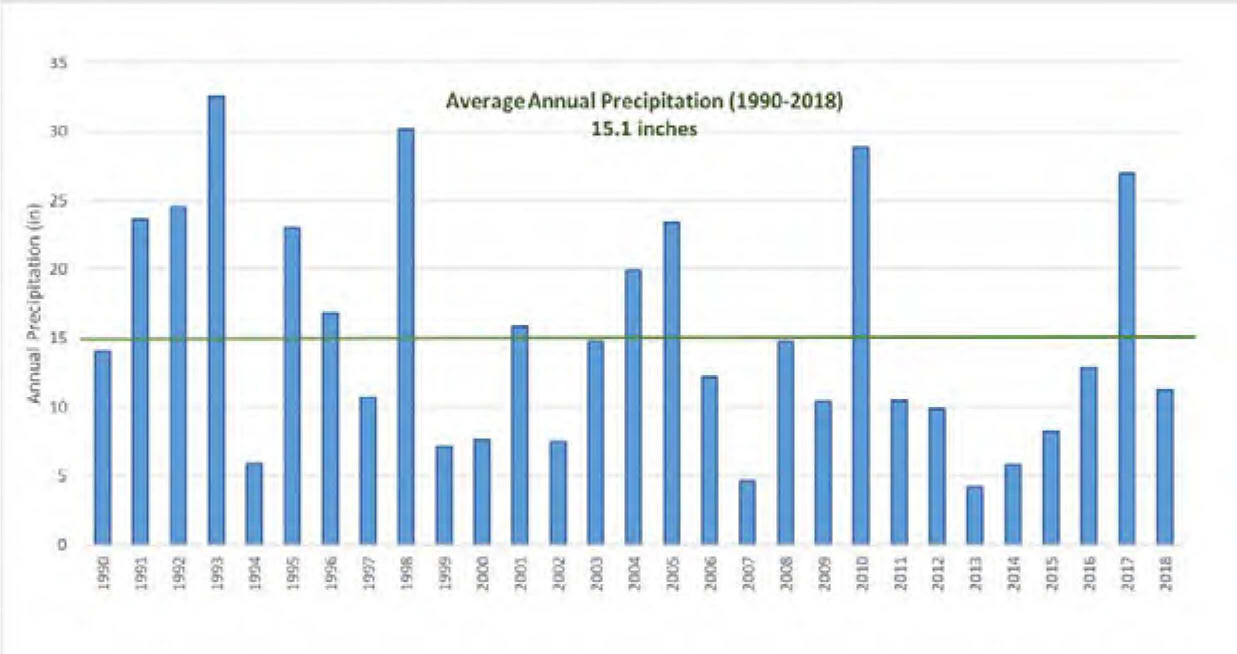

Figure 2. Historical Annual Regional Rainfall (Pomona CIMIS Station #78)

2.3 Regional Water Demand Forecasts

Within the IEUA service area, water demand since 1995 has increased by approximately 20 percent, despite a regional growth of 30 percent. This is indicative of new water use behaviors, including increasing efficiency in outdoor irrigation and indoor fixtures. This improved efficiency prolongs the availability of current regional water supplies into the future.

More recently, census data for 2014 to 2017 shows that annual population growth rates have been slightly less than one percent per year. Table 2 provides the regional municipal and industrial (M&I) water demand forecasts for 2020 and 2040 as reported in the IEUA 2015 Integrated Water Resources Plan (IRP). The IRP demand forecasts were developed based on the member agencies' Urban Water Management Plans (UWMPs). Three ranges of growth were reported based on varying assumptions related to future developments, housing density, and water practices.

Table 2. M&I Regional Demand Forecast (from 2015 IRP)

Total Regional Demand Forecast (AC-FT)	2020	2040
High Demand Forecast[1]	230,000	267,000
Medium Demand Forecast[2]	220,000	238,000
Low Demand Forecast[3]	212,000	217,400

1. *Traditional development and current usage patterns (55 GPCD indoor water use).*

2. *Higher density development based on the Southern California Association of Governments (SCAG) Regional Transportation Plan (RTP) average housing density. Existing outdoor use is limited to 70% of reference evapotranspiration (ETo). Future outdoor use is limited to 60% ETo, and indoor water use is reduced from 55 GPCD in 2015 to 35 GPCD by 2040 for new development.*
3. *High density development based on the SCAG RTP high housing density. Existing outdoor use is limited to 70% of reference ETo and future outdoor use is limited to 60% ETo. Indoor water use is reduced from 55 GPCD in 2015 to 35 GPCD by 2040 for new development.*

2.4 Planning Steps

The Drought Contingency Plan was developed following the USBR "*Guidance Regarding the Drought Contingency Planning Process"* as a framework. Below are the steps undertaken to develop the plan, resources utilized, and the associated deliverables.

Table 3. Planning Steps

Approach/Steps	Resources Utilized	Deliverable
Step 1		
Reviewed regional and local master planning documents and determined goals and factors impacting the DCP.	▪ 2009 IEUA Drought Response Plan ▪ 2015 IEUA Integrated Water Resources Plan ▪ 2015 IEUA Water Use Efficiency Business Plan update ▪ 2015 Urban Water Management Plans – local and regional ▪ Recharge Master Plan Update ▪ MWD Water Surplus & Drought Management Plan ▪ MWD Water Savings Allocation Plan ▪ Existing IRP modeling data	Drought Goals documented
Step 2		
Created a framework for predicting and confirming future droughts by establishing data metrics used to indicate drought conditions in the region.	▪ Input and collaboration from the *DCP Taskforce* meetings	Drought Monitoring Technical Memo
Step 3		
Evaluated the risks and impact of current and future drought in the IEUA service area. Assessed the region's vulnerabilities in terms of water supply reliability for each water supply type and effects by climate change, growth and other reliability factors.	▪ 2015 IEUA Integrated Water Resources Plan ▪ Chino Basin Regional Water Supply Infrastructure Model results	Vulnerability Assessment Technical Memo

Approach/Steps	Resources Utilized	Deliverable
Step 4		
Developed mitigation actions	▪ Chino Basin Water Master's Optimum Basin Management Program (2000) ▪ Chino Basin Organics Management Strategy (2001) ▪ Recycled Water System Feasibility Study (2002) ▪ Wastewater Facilities Master Plan (2002) ▪ 2015 IEUA Integrate Resource Plan	Mitigation Actions Technical Memo
Step 5		
Developed strategies and response actions for each stage of drought condition.	▪ Consensus outputs from *Response Actions Taskforce* meetings ▪ 2015 IEUA WUE Business Plan ▪ 2015 – 2018 WUE Program Activity and Final Reports ▪ 2011 – 2017 Customer Water Use	Drought Response Action Plan (Communications & Outreach Plan)
Step 6		
Developed and documented the roles, responsibilities and procedures for ongoing monitoring, vulnerability assessment, mitigation and response actions.	▪ Feedback and outcomes from taskforce meetings	Operational & Administrative Framework
Step 7		
Produced comprehensive Drought Contingency Plan.	▪ Drought Monitoring Technical Memo ▪ Vulnerability Assessment Technical Memo ▪ Mitigation Actions Technical Memo ▪ Drought Response Action Plan (Communications & Outreach Plan)	Drought Contingency Plan

The DCP was developed in coordination with IEUA's eight retail member agencies. IEUA invited representatives from each member agency's management, planning and conservation groups as well as other stakeholders including representatives from Chino Basin Watermaster, Water Facilities Authority and the Chino Basin Water Conservation District.

There were five workshops held over a two-year period, starting in September 2017 and concluding in September 2019. The Drought Contingency Taskforce members were given the opportunity to review and comment on technical memorandums for each plan component and the draft DCP, as well as to guide the development of the plan.

Below is the list of DCP Taskforce participants and their respective organizations:

The first workshop on December 11, 2017, served as an initial kick-off meeting to review the purpose and scope of the DCP, as well as to establish the participants for future workshop. The subsequent four workshops were held to review the results for each component of the plan.

The dates and topics discussed for each of the workshops are shown in Figure 3. Also shown in Figure 3 are the interim draft materials that were shared for review and comment by the taskforce, including the:

- Annotated DCP outline
- Drought Monitoring Technical Memorandum
- Vulnerability Assessment Technical Memorandum
- Mitigation Actions Technical Memorandum

In addition, one-on-one meetings were held between IEUA and member agencies as needed in order to provide an added forum for discussion and clarification.

DCP Technical Taskforce Workshop Schedule

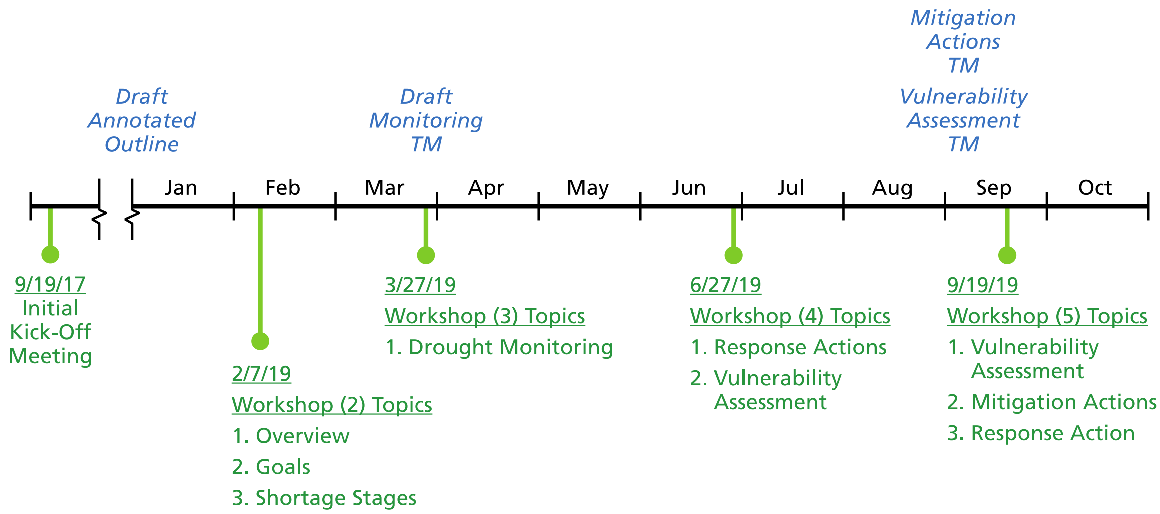

Figure 3. DCP Technical Taskforce Workshop Schedule

During this same time period, a Response Actions Taskforce was operating with the mission to create the Response Action (Communication & Outreach) Plan. The response action taskforce was comprised of retail member agency conservation staff and IEUA.

Below are the IEUA and Retail Agency participants:

Response Actions Taskforce Participants

3 Drought Monitoring

The **Drought Monitoring Framework** provides the tools to determine the existence and severity of a drought or water shortage.

This framework will rely largely on the knowledge and expertise of IEUA's member agencies for interpretation of real time conditions and prediction of future supply. IEUA's role is to act as the facilitator to, track potential water shortages through MWD, gather supply data from retail member agencies, consolidate the data and calculate the supply-demand index. It's important to note that the supply types and portfolios within the IEUA service area are extremely diverse, and the availability of supply types can depend on many factors.

There are four primary components to the drought monitoring framework:

1. **Indicator Data Collection and Distribution**- Key imported water availability indicators will be compiled and provided to the member agencies annually.

2. **Member Agency Reporting**- Based on the provided indicator data and their own monitoring activities, the member agencies will provide their annual forecast for available local supplies and demands.

3. **Regional Supply-Demand Index Calculation**- The agency projections will be combined to formulate a regional supply-demand ratio (or index).

4. **Shortage Classification**- The regional index will be used to classify the level of water shortage (if any).

Simply stated, the assessment looks at current and future projected water supplies as compared to current and projected water demand. Should there be a downward shift in available water supplies or an increase in customer demand, IEUA and its member agencies will determine the severity of the change, the categorized stage level, and the determine the required response.

This Drought Monitoring section:

- Provides background and operational information on the IEUA service area supply types and their conditions.

- Summarizes and describe the data to be used for monitoring each of the water supplies (also called indicators).

- Describes the member agency reporting process for the drought monitoring framework.

- Defines the water shortage stages to be implemented within the drought monitoring framework and associated regional supply-demand index calculation.

3.1 Drought Indicators

Given the diversity in the supply types and portfolios within the IEUA service area, the data available to inform water supply availability and conditions are abundant and often interconnected. The supply types reviewed here include Chino Basin groundwater, non-Chino Basin groundwater, imported water, and local surface water.

3.1.1 Groundwater

Chino Basin Groundwater

The Chino Basin is an adjudicated groundwater basin and is one of the largest groundwater basins in Southern California. San Bernardino County Superior Court created the Chino Basin Watermaster (CBWM) in 1978 as a solution to lawsuits over water rights. The CBWM is responsible for management of the Chino Basin in accordance with the Judgement, 2000 Peace Agreement, 2007 Peace II Agreement, and the Chino Basin Optimum Basin Management Program (OBMP).

Water rights in the Chino Basin are held by representatives of three stakeholder groups, called Pools. The three Pools are:

- Overlying Agricultural Pool: representing dairymen, farmers, and the State of California
- Overlying Non-agricultural Pool: representing area industries
- Appropriative Pool: representing local cities, public water districts, and private water companies

The court judgment allocates groundwater rights by establishing an annual pumping “safe yield” for each Pool. The Operating Safe Yield (OSY) is the annual amount of groundwater that can be pumped from the basin by the Pool parties, free of replenishment obligations. Annual groundwater production in excess of the OSY is allowed by the adjudication, provided that the pumped water is replaced and recharged back into the groundwater basin. In addition, stakeholders within the different Pools can reach agreements to exchange groundwater rights for other water sources. For example, there have been agreements between dairymen in the agricultural pool and purveyors in the appropriative pool to exchange recycled water for groundwater rights. The OSY and the average total groundwater production since 1978 for each Pool is summarized in Table 4.

Table 4. Chino Basin Groundwater Operational Safe Yield and Historical Production

Stakeholder Pool	Operational Safe Yield[1] (AF)	Average Groundwater Production[2] 1977-2017 (AF)
Agricultural	82,800	42,248
Non-agricultural	7,366	3,984
Appropriative	54,834	97,215
Total	145,000	143,447

[1] Values represent the OSY from 1978 to June 2018. The appropriative rights toward the safe yield were reduced by 5,000 AF to 49,834 AF in June 2018.
[2]Based on the 41st Annual Chino Basin Report (Fiscal Year 2017-18) (http://www.cbwm.org/rep_annual.htm**)**

The quantity of groundwater stored in the Chino Basin has been carefully managed by the CBWM. Currently, there are numerous efforts to increase the amount of groundwater recharge. There are 19 active spreading basins that are operated to capture stormwater, recycled water, and/or imported water for recharge into the Chino Basin. The safe storage for the groundwater basin was previously defined as 500,000 acre-feet (AF), and there are investigations underway regarding the feasibility of increasing that storage to as much as 1,000,000 AF.

The water quality in the southern portion of the Chino Basin has been impacted by historical agricultural uses and now has high levels of nitrate and total dissolved solids (TDS) in certain areas. There are also some areas that exceed standards for perchlorate and volatile organic chemicals (VOCs). Most recently, there have been growing concerns around the occurrence of perfluorinated chemicals (PFOS and PFOA) and there are efforts to understand their occurrence in the regional water supply as they may become subject to regulatory limits.

Lower quality groundwater requires additional treatment, and/or blending with higher quality imported water. The CBWM works in partnership with local municipalities, IEUA, and the Santa Ana Regional Water Quality Control Board to address these water quality issues. In addition, IEUA is part of a Joint Powers Agency, the Chino Basin Desalter Authority (CDA), which was formed to manage the production, treatment, and distribution of treated potable water. Treatment occurs at two plants – Chino I and II Desalters – to remove salts and volatile organic chemicals through reverse osmosis, ion-exchange, and air stripping. A detailed summary of the general conditions of the Chino Basin can be found in the 2016 State of the Basin Report on the CBWM website. The 2016 State of the Basin is an atlas-style report with maps and figures displaying the conditions and trends within the basin.

Because of these conditions, the availability of Chino Basin groundwater is largely driven by quality as opposed to quantity. For example, for the period of 2009 to 2018, Chino Basin groundwater comprised roughly 15 percent of the total water supply for the Chino Hills service area (not including the water received from the CDA, which comprised 26 percent of the annual supplies for the same time period). However, in 2018, quality concerns in their area required that all groundwater wells within the service area be taken offline for an extended duration and alternative water supplies be utilized. The resiliency of the regional supply portfolio and the interconnections between the member agencies facilitated access to alternative water supplies.

The availability of real-time groundwater quality data within the Chino Basin varies significantly depending on location, well type, and constituent of interest, complicating the selection of groundwater availability indicators for the IEUA drought monitoring framework. However, due to the active management and monitoring of the basin by the CBWM, along with each of the IEUA member agencies and other stakeholders, the conditions and availability of the groundwater are generally known by the stakeholders. The drought monitoring framework will rely on the collective expertise of the IEUA member agencies and their water managers to define groundwater availability conditions and inform the regional drought monitoring framework.

Non-Chino Basin Groundwater

There are four agencies within the IEUA service area that utilize groundwater from basins adjacent to the Chino Basin as a water supply source: Upland, Cucamonga Valley Water District (CVWD), Fontana Water Company (FWC), and San Antonio Water Company (SAWCo). The additional basins include Cucamonga, Rialto, Lytle Creek, Colton, and the Six Basins groundwater basins. The Six Basins are comprised of the Ganesha, Live Oak, Pomona, Lower Claremont Heights, Upper Claremont Heights and Canyon Basin. These basins combined provided approximately 13 percent of the regional water supply portfolio between 2009 and 2018.

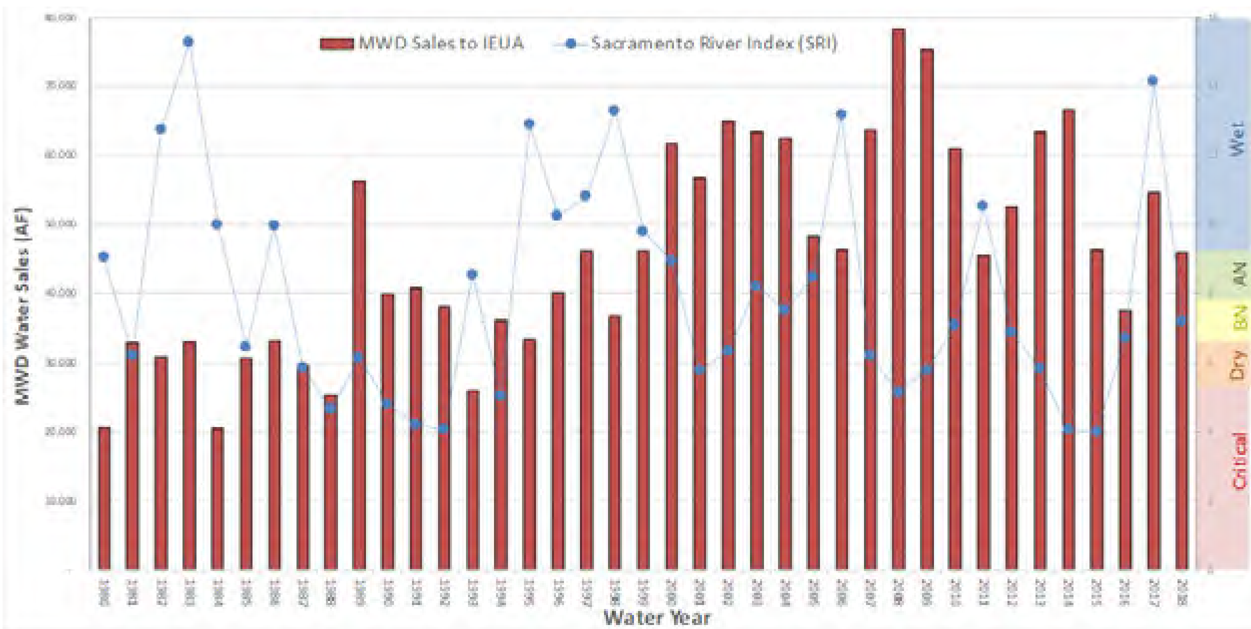
The trends and conditions in other groundwater basins are unique and the supply availability has specific implications for each member agency. The drought monitoring framework will allow the member agencies relying on non-Chino Basin groundwater to provide their insights into the conditions of each of the groundwater basins. The member agencies' individual insights will serve as the key indicators for non-Chino Basin groundwater.

3.1.2 Imported Water

IEUA began importing supplemental surface water to the Chino Basin from MWD in 1951. While MWD also imports water from the Colorado River, the State Water Project (SWP) is the primary source of imported water supplies delivered to IEUA. The SWP originates along the Feather River (a tributary to the Sacramento River), hundreds of miles north of IEUA, and includes facilities to pump and convey water from the Sacramento-San Joaquin River Delta (Delta) to Southern California as well as to the San Francisco Bay Area, the San Joaquin Valley, and the Central Coast. From 2009 to 2018, imported water supplies delivered by MWD have accounted for roughly 25 percent of the water supplies in the IEUA service area.

There are numerous conditions that contribute to the relative availability of the imported water supplies, including current hydrologic conditions along the Feather and Sacramento Rivers and in the Delta, the regulatory restrictions on Delta exports, the amount of water remaining in SWP storage facilities from previous years, the conditions of the conveyance infrastructure south of the Delta, the water management strategies of MWD, and numerous other operational and legal constraints. While some of these constraints can be difficult to quantify or consolidate, there are several metrics available to quantify the hydrologic conditions of the Feather and Sacramento Rivers that may be useful in predicting the availability of imported supplies.

The Sacramento River Index (SRI) published by DWR provides a quantification of Delta inflows from the Sacramento River by estimating the sum of runoff for the four major rivers within the river basin (Sacramento, Feather, Yuba, and American Rivers). The SRI is reflective of the overall water year and classifies each year as wet, above normal, below normal, dry, or critical. The historical relationship between imported water availability in the IEUA service area and the hydrologic conditions in the Sacramento River basin was examined by comparing the SRI to historical MWD deliveries to IEUA (see Figure 5). This comparison indicates that hydrologic conditions in the Sacramento River basin are not directly correlated with imported water deliveries in that year.



Note: A data request was fulfilled by MWD for all water sales to IEUA from water years 1980 to 2018. Categories include: Agricultural, Full Service, Interruptible Programs, Local Projects, and Storage Programs. Of these categories, Full Service and Interruptible Programs were summed to determine MWD deliveries that meet municipal demand. Agency Sales Report data for 29 water years (1980 to 2018).

Figure 5. MWD Water Sales to IEUA with the Sacramento River Index (SRI)

Since water year 2000, the largest and second largest MWD sales occurred in critical and dry years, respectively. Deliveries for water years classified as wet or above normal typically coincide with relatively average deliveries. This indirect relationship between hydrologic conditions and water deliveries is indicative of MWD and IEUA's long-term water management strategies, including use of carryover storage from year to year and real-time portfolio management to optimize use of available sources of water to meet water demands in any given year.

MWD actively monitors and manages the water supplies it imports to the region to assess availability and predict shortages. In response to critically dry conditions in the early 2000s and federal court rulings to protect the Delta Smelt in 2007 (which tightened regulations on Delta exports), MWD developed the Water Supply Allocation Plan (WSAP) to help manage uncertainty in the SWP's future water availability. The WSAP includes the specific formulas for determining member agency supply allocations in a fair and reasonable way and the key implementation elements needed to administer an allocation should a shortage be declared. The framework of the WSAP includes an allocation year that spans from July to June, with a declaration in April.

The key dates for the WSAP monitoring and declaration process are as follows:

January to March: Water Surplus and Drought Management reporting process provides updated information on storage reserve levels, projected supply, and demand conditions to the MWD Water Planning and Stewardship Committee meetings.

April: Member agencies report their projected local supplies for the coming allocation year (July to June) to update projected supplies. Staff analysis of storage reserves and projected supply and demand conditions provide an allocation recommendation to the MWD Board of Directors. This allocation is effective starting July 1 and held through the following June 30.

A 10-level Shortage Allocation Index determines the Wholesale Minimum Allocation and the Maximum Retail Impact Adjustment. Wholesale Minimum Allocation is defined as the minimum amount of MWD-supplied wholesale water service provided to each member agency. The Maximum Retail Impact Adjustment ensures that agencies with a high level of dependence on MWD do not encounter unequal retail shortages when experiencing a reduction in wholesale supplies.

In addition to the Wholesale Minimum Allocation and Retail Impact Adjustment, a Conservation Demand Hardening Credit and Minimum Per-Capita Water Use Credit are considered to determine the total WSAP Allocation. The allocation to an agency for its municipal and industrial retail demand is the sum of these four calculations, which are described in detail in the Appendix of the WSAP.

July to June: Member agencies are requested to submit their local production on a monthly basis and certify end of allocation year local supply use. Local production data must be reported to MWD by the end of the month following the month of use (i.e., use in July must be reported by the end of August). This information is combined with MWD sales information to track retail water use throughout MWD's service area. Each month MWD reports on member agency water sales compared to their allocation amounts.

June 30: Allocation year is complete.

August: MWD calculates potable water use based on supply certifications and actual sales data for the previous allocation year (July to June). Allocation surcharges are assessed for usage above a given member agency's final adjusted allocation.

Given the complexity of the various factors influencing the availability of imported water, the drought monitoring framework will rely on the monitoring efforts and allocation procedures of MWD to inform the availability of the imported supplies.

3.1.3 Local Surface Water

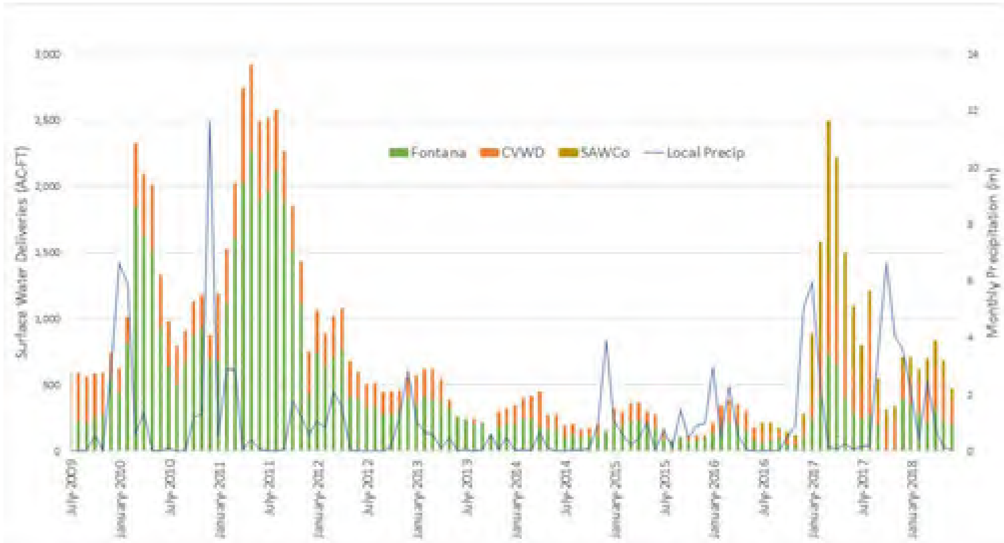
Three IEUA member agencies utilize local surface water supplies to meet demand, CVWD, Fontana Water Company, and SAWCo.

CVWD local surface water supplies come from streams, springs, and tunnels within canyons located in the northern area of the CVWD boundary. CVWD has rights to six sources of canyon water, three of which are currently utilized (Cucamonga Canyon, Day/East Canyon, and Deer Canyon). Based on historical data, CVWD estimates a reasonable available volume of 4,540 acre-feet per year (AFY) from local surface water supplies.

Fontana Water Company receives local surface water supplies from Lytle Creek, which is then treated at the Sandhill Plant. Lytle Creek supplies from 2011 to 2015 averaged 6,250 AFY. The Lytle Creek sum is augmented with water obtained from the Grapeland Tunnel. The Grapeland Tunnel has extensive collector lines in the Lytle Creek Canyon tributaries and a large line running below the streambed of Lytle Creek.

SAWCo has rights to surface flow from San Antonio Creek that are pre-1914 rights and over the years have been supported by Court Judgments per a confidential report entitled "Opinion Re Water Rights of San Antonio Water Company," dated June 1993. In 2011, a wet year, SAWCo diverted 8,800 AF from San Antonio Creek. The average diversion from 2012 to 2015 was 1,963 AFY.

Figure 6 compares the monthly local surface water deliveries for Fontana Water Company, CVWD, and SAWCo with monthly precipitation from a nearby weather station (CIMIS Station #78, Pomona). Local surface water supplies for each of these member agencies are highly reliant on local precipitation, and months of high local precipitation typically correspond with a greater volume of local surface water supply for the months to follow. Local precipitation provides a helpful predictor for local surface water availability and is a valuable indicator for the drought monitoring framework.



Note: Local precipitation was collected from CIMIS station in Pomona (#78). A Chino CIMIS station (#255) was added in March 2018 and could be used for future applications.

Figure 6. Historical Local Surface Water Supplies and Local Precipitation

3.2 DROUGHT MONITORING

The supply types and portfolios within the IEUA service area are extremely diverse, and the relative availability of supply types can depend on many factors. The IEUA drought monitoring framework will rely largely on the knowledge and expertise of IEUA's member agencies to interpret real-time conditions and predict and define regional water shortages due to the disparate nature of the indicators of drought conditions throughout the region. There are four key cornerstones of the IEUA drought monitoring framework as described below and shown in Figure 7.

- **Indicator Data Collection and Distribution.** Key imported water availability indicators will be compiled and provided to the member agencies annually.
- **Member Agency Reporting**. Based on the provided indicator data and their own monitoring activities, participating member agencies will provide their annual projections for supplies and demands within their service area once a year.
- **Regional Supply-Demand Index Calculation**. The agency projections will be combined to formulate a regional supply-demand ratio (or index).
- **Shortage Classification.** The regional index will be used to classify the level of water shortage (if any).

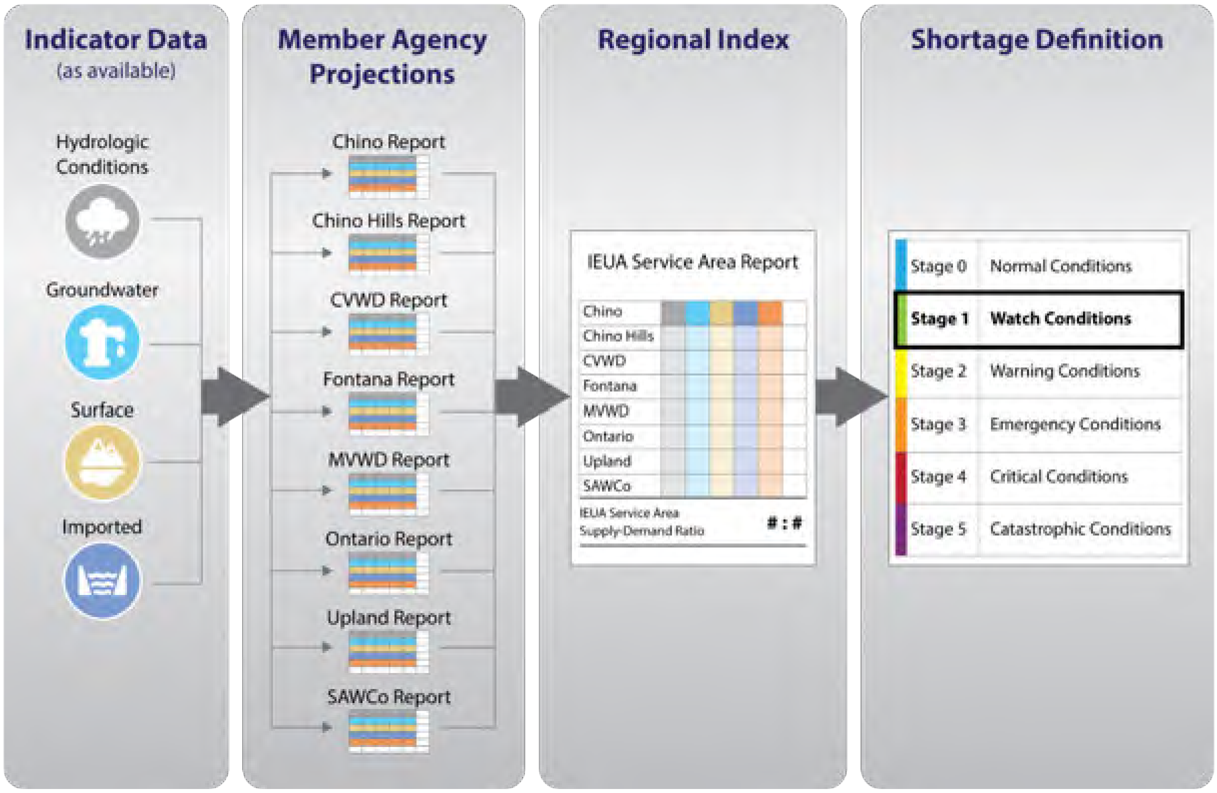


Figure 7. IEUA Regional Drought Monitoring Framework

3.2.1 Reporting Framework

The drought monitoring reporting will occur on an annual basis and will be a two-step process. First, key water supply indicators for imported water will be compiled into a standardized report and distributed to the water managers from each member agency. This will include projected deliveries of imported water from MWD in addition to any potential forecasts for shortages. IEUA will also provide estimated demand projections to the participating member agencies, as a reference or guide, based on a five-year historical average.

Second, each retail member agency will report their projected local supplies and demand for the coming year. Figure 8 below is the information obtained from each member agency that will be utilized to generate the supply-demand ratio.

Annual Supply Projections					
Agency	Local Groundwater	Surface Water	Imported Water	Annual Demand	Supply Shortage
Chino					
Chino Hills					
Fontana Water Company					
Ontario					
Upland					
Cucamonga valley Water District					
Monte Vista Water District					
San Antonio Water Company					

Figure 8. Sample Reporting Framework

This reporting time frame and structure was selected because it piggy-backs the annual reporting time frame conducted by IEUA, the retail member agencies and MWD.

As well, there is an additional review process. IEUA has an established monthly forum to provide and receive updates from the member agencies on water supply conditions. IEUA hosts member agency Water Manager meetings each month, where the managers review supply conditions, demand shifts and regulatory changes that may impact supply. If local circumstances or external drivers significantly shift, IEUA will request updated local supply data from respective member agencies. As with the annual reporting, this information will be used to determine if there is a regional water shortage due to these factors.

3.2.2 Supply and Demand Ratios

The supply and demand ratios for each year will be calculated based on the projections provided by the water managers. The data will be compiled into a singular supply-demand ratio for the IEUA service area. The regional supply-demand ratio will serve as the trigger to inform the regional water shortage.

Figure 9, on the following page, provides an example compilation of member agency projections and the calculation of the regional supply-demand ratio. There will be considerations for expected shortages for individual member agencies that may not be reflected in the regional ratio.

Between reporting periods, the participating member agencies will continue their individual monitoring activities. Each of the member agencies have developed their own approach to monitoring their supplies and have established unique definitions and responses for localized shortage conditions. *Appendix B:*

Summary of Member Agency Water Shortage Stages provides an overview of each agencies' shortage definitions and responses.

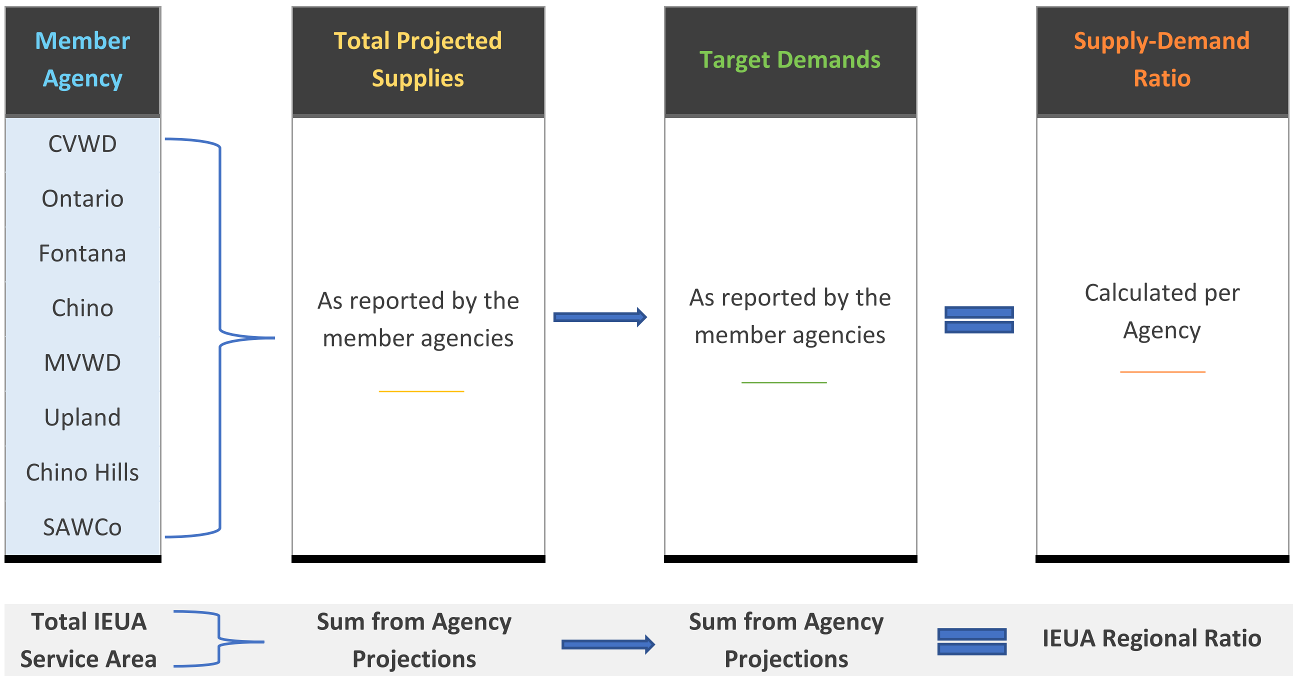

Figure 9. Annual Regional Supply and Demand Projects for IEUA Service Area

3.2.3 Water Shortage Stages

Stages will be defined based on the calculated supply-demand ratios for the IEUA service area. The water shortage stages and descriptions are shown in Table 5.

These stages will be used to help the Drought Response Taskforce identify the most appropriate regional responses for the anticipated shortages.

The stages are in compliance with the newly passed state legislation (SB 606 and AB 1668), which now requires drought plans to be standardized and include six stages of drought severity. These stages were developed in consultation with each of the member agency's own definitions for local drought or water shortage levels and can be viewed in *Appendix B: Summary of Member Agency Water Shortage Stages.*

It is important to understand that the stage is calculated and declared for the overall region, and at the time, a local retail agency may have a water supply level that varies from the regional stage due to the uniqueness of their water supply mix. When this occurs, the local agency may develop customer messaging that clarifies that their agency is not directly impacted to the same level as the region.

Water shortage stages and triggers for IEUA region are below:

Table 5. IEUA Regional Water Shortage Stages

Drought Stage:	Stage Descriptions:	Triggers:
Stage 0	Normal Conditions	No water shortages anticipated.
Stage 1	Watch Conditions	IEUA regional ratio is predicting shortages between 1% and 5%.
Stage 2	Warning Conditions	IEUA regional ratio is predicting shortages between 6% and 15%.
Stage 3	Emergency Conditions	IEUA regional ratio is predicting shortages between 16% and 25%.
Stage 4	Critical Conditions	IEUA regional ratio is predicting shortages between 26% and 50%.
Stage 5	Catastrophic Conditions	IEUA regional ratio is predicting shortages greater than 50%.

4 Vulnerability Assessment

In the western part of the United States, climate change is predicted to cause increased temperatures, less mountain snowpack, more severe and frequent droughts, changes in runoff patterns and overall negative impacts on regional water supplies.

Climate related factors may make it more challenging for water planners to manage demand needs. Add population growth into the mix and the picture becomes even more complicated.

A **vulnerability assessment** predictively identifies, quantifies, and prioritizes the potential susceptibilities of a region's complex and dynamic water supply sources. The assessment takes into consideration climate conditions, as well as other factors such as environmental and political policy, and population growth.

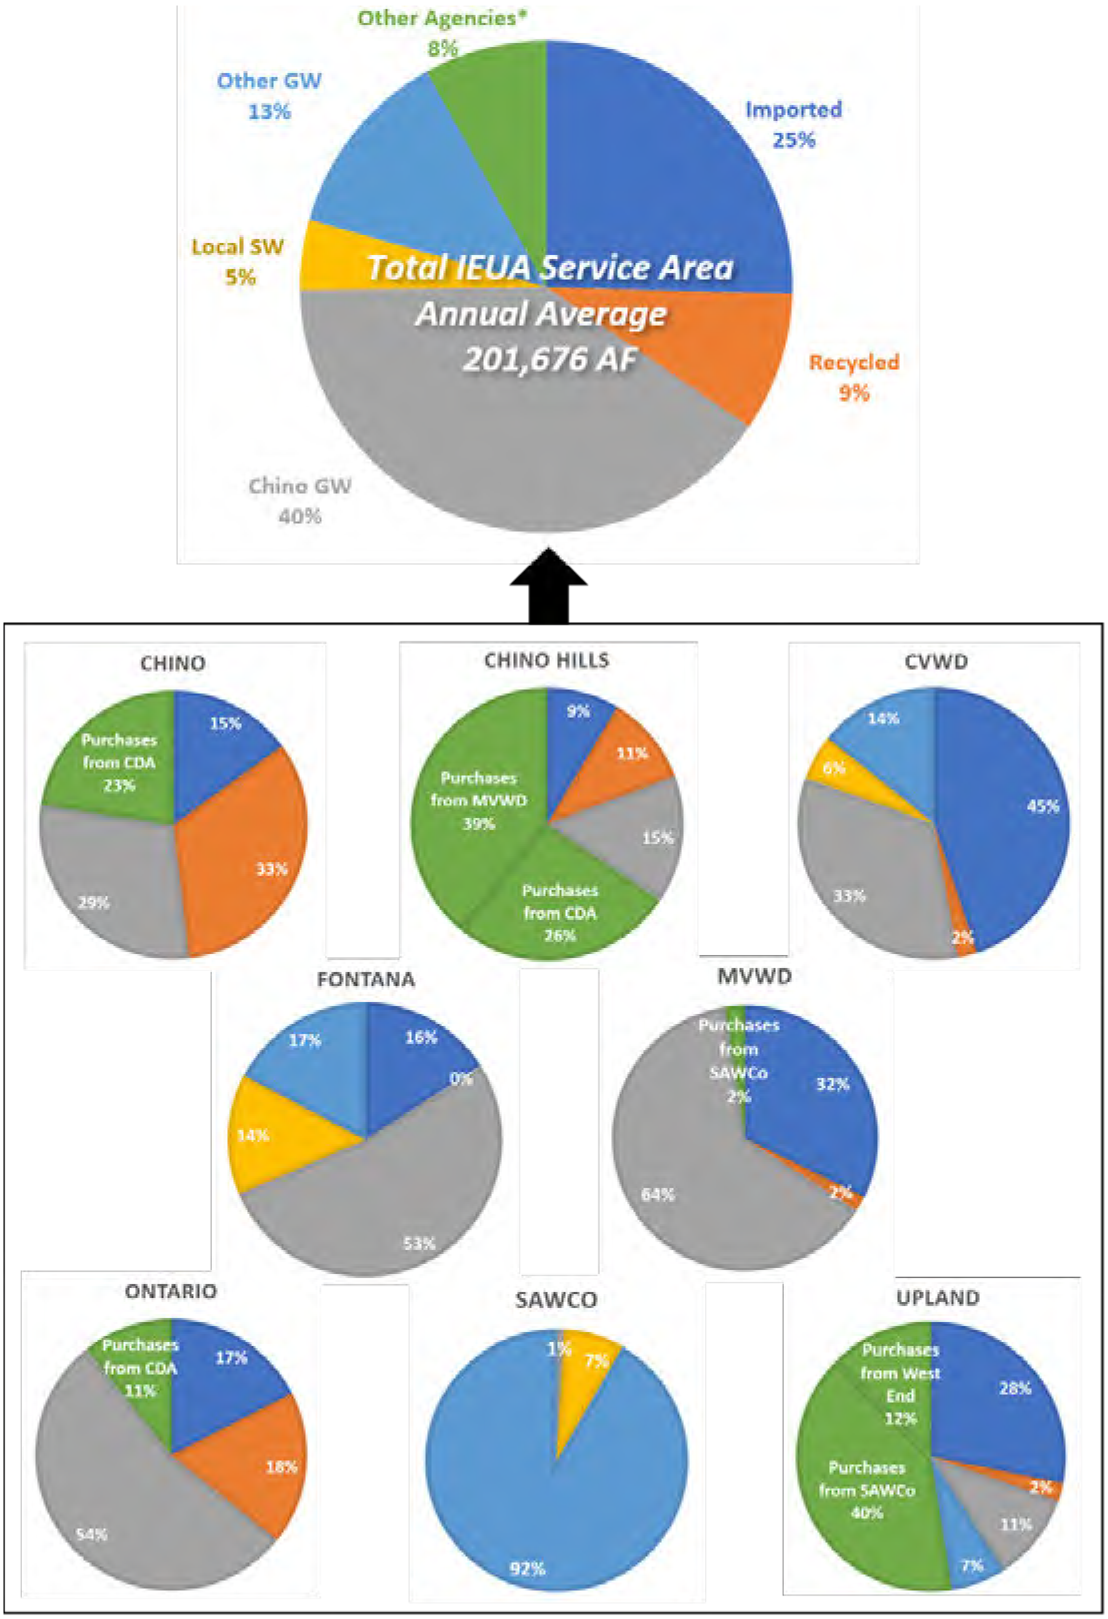
The desired outcome of the vulnerability assessment is to improve understanding of 1) the potential for, and 2) the characteristics of, future drought conditions.

This section is organized into four parts.

> **First**, the regional water resources are reviewed and described.
>
> **Then**, potential future conditions are discussed related specifically to climate change and growth and how they may impact each of the regional water supply types.
>
> **Next**, results from IEUA's Integrated Resource Plan modeling efforts, which explores the potential impacts to the regional water supplies based on simulated future scenarios, are presented.
>
> **Lastly**, the key vulnerabilities are reviewed and discussed.

4.1 Regional Water Supplies

As described in previous sections, the region relies on imported water, groundwater from both the Chino and non-Chino groundwater basins, IEUA-supplied recycled water, exchanges and purchases from other agencies, and local surface water from local creeks and canyons to meet demands. The composition of the regional and member agency supply portfolios based on the average annual deliveries from 2009 to 2018 are shown in Figure 10. Chino Basin groundwater provides the largest portion of the annual regional supply at 40 percent and imported water accounts for about 30 percent. Each of the member agencies also has their own unique portfolio as shown in Figure 10.



Note: "Other Agencies" in the regional portfolio are reflective of purchases from non-member agencies. The member agencies' supply portfolios show all purchases (whether from member or non-member agencies).

Figure 10. Regional and Member Agency Supply Portfolios (2009-2018 Averages)

4.2 Future Conditions

This section addresses predictive impacts to regional water resources and imported supply resulting from growth, climate change, and other possible factors. To support this process, resource information was gleaned from the following sources:

- California's Fourth Climate Change Assessment (2018 CCCA)
    - Mean and Extreme Climate Change Impacts on the State Water Project [CCCA SWP]
    - Los Angeles Region Report [CCCA LA]
- IEUA's Integrated Water Resources Plan (2015 IRP)
- IEUA's Climate Change Action Plan (2018 CCAP)

The CCCA's Los Angeles Region Report was utilized because it encompasses Los Angeles, Ventura and Orange counties, and most importantly, urbanized portions of San Bernardino County.

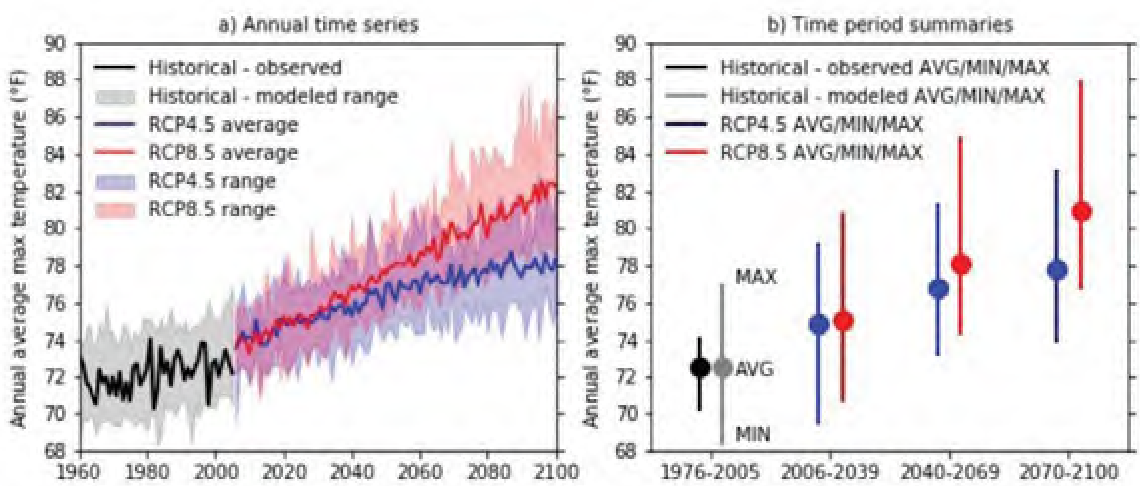
Los Angeles region topography and boundary definition as a solid red line, which encompasses Los Angeles, Ventura, and Orange Counties, and adjacent urbanized portions of San Bernardino and Riverside Counties.

Like the rest of the state, the Los Angeles region is expected to face a challenging combination of decreased water supply and increased water demand. The future reliability for IEUA's water resources are dependent upon climate conditions (both local and at the source of supplies), environmental and political drivers, and growth. Climate change-induced temperature increases, changes in runoff patterns, and drought are some of the key factors that will have a substantial impact on regional water supplies. Additionally, growth in the region will create new demand for potentially strained water supplies. The effects of climate change and growth are discussed in a general sense in Sections 4.2.1 and 4.2.2, respectively. Regional water supplies within the IEUA service are then summarized and analyzed through three lenses: climate change, growth, and other supply reliability factors.

4.2.1 General Effects of Climate Change

The effects of a changing climate are apparent throughout California, including increased temperatures, prolonged drought, rising sea levels, severe atmospheric river events, and extreme wildfires. Figure 11 shows the predicted trends for temperature in the Los Angeles area, as reported by the CCCA LA report, based on global climate models. In the figure, modeled scenarios are described as Representative

Concentration Pathways (RCP) 4.5 and 8.5. RCP4.5 represents a mitigation scenario where global CO_2 emissions peak by 2040, while RCP8.5 represents a "business-as-usual" scenario where CO_2 emissions continue to rise throughout the 21st century. Both scenarios show a predicted increase in average temperatures in the Los Angeles region. Though projections are similar during the early 21st century regardless of the emissions scenario, later in the 21st century the projections diverge as emissions continue to rise under RCP8.5 and they level off in the mid-century under RCP4.5. Based on the modeled results, average annual temperatures in the region could rise 4 to 5 degrees Fahrenheit by the mid-21st century, and 5 to 8 degrees Fahrenheit by the late 21st century.



Historical-observed (black), historical-modeled (grey), and projected future (RCP4.5 - blue, RCP8.5 - red) annual average maximum temperature over the LA region. (a) Annual time series of data (future projections begin in 2006), with solid lines representing model-averages and shading representing model spread. (b) Summary of model-average (circles) and spread (vertical lines) across four time periods: 1976-2005 (historical), 2006-2039 (early-21st century), 2040-2069 (mid-21st century), and 2070-2100 (late-21st century). Unit is °F.

Source: CCCA LA

Figure 11. Historical and Projected Temperatures for the Los Angeles Region

Annual precipitation in the Los Angeles/San Bernardino region is highly variable and a significant portion of the regional rainfall is concentrated in the winter months from November to April. Figure 2 (provided in Section 2) shows the annual precipitation from 1990 to 2018. As the figure shows, while the average annual precipitation is slightly more than 15 inches, there have been very few years that have reflected that average. There are typically years with much greater than average precipitation or much less. The climate science regarding the future magnitude and timing of precipitation in the region is still an active area of research, though the consensus is that dry and wet extremes are both expected to increase in the future (CCCA LA); meaning that, while the projected average annual precipitation may align with historical trends, the wet years will likely be wetter and the dry years drier, thus exacerbating an already highly variable water supply reliability factor.

The reliabilities of imported surface water, local groundwater, recycled water, and local surface water are all susceptible to the effects of climate change and are discussed in the following sections.

4.2.2 General Effects from Growth

Population growth within IEUA's service area creates new demand for water supplies, but regional planning efforts such as IEUA's 2015 IRP and 2018 CCAP provide a path forward that strives to decrease demands and optimize resource allocations. Through thoughtful planning and development, sustainable growth within IEUA is a probable outcome. In the 2015 IRP demand analysis, it was found that per capita water usage decreases as development trends shift toward higher density and smaller landscaped areas. Also, the public has shown a willingness to reduce total water usage in response to statewide calls for conservation. Both factors suggest that increases in population do not necessarily constitute substantial increase in water use.

4.2.3 Groundwater

Groundwater within the IEUA service area is, and will continue to be, crucial to the water supply portfolio. The Chino and non-Chino Basin groundwater supplies have accounted for 53 percent of the regional supply portfolio for the last decade. In addition, each of the member agencies rely, to some degree, on groundwater to meet their annual demands. Per the 2015 IRP, the baseline amount of groundwater production between 2020 and 2040 is assumed to be 91,300 AF for Chino Basin, and 22,000 AF for non-Chino basins.

Future conditions for Chino and non-Chino Basin groundwater are discussed below through the lenses of climate change, growth, and other reliability factors.

Climate Change Impacts

It is anticipated that the groundwater supply will likely be adversely impacted by climate change-induced temperature increases and drought. As discussed above, impacts of climate change for the Los Angeles/San Bernardino region are likely to include increased temperatures and more extreme precipitation events. Groundwater elevation and water quality within the region are both dependent upon rainfall and supplemental sources of recharge. Although the effect of climate change on precipitation in California is still unclear, more frequent occurrences of extreme events similar to the 2011 to 2017 drought could significantly decrease natural groundwater recharge. In addition, as other supplies become constrained in a drought situation, there is potential for less water availability for groundwater recharge purposes. Current supplies utilized for groundwater recharge include surface water, imported water, and recycled water. The 2015 IRP, which was informed by model simulations performed by Wildermuth Environment Inc., showed that natural groundwater recharge would decrease by 0.44 percent for each 1 percent decline in long-term precipitation. A key conclusion drawn from the simulations is that it is important to secure supplemental water when available to recharge the Chino Basin (through direct or in lieu practices) to enable increased groundwater production during droughts and emergencies (2015 IRP).

Groundwater quality is susceptible to climate change because as other sources become less available, groundwater will likely be more heavily relied upon, and if, in addition to those stresses, recharge is also reduced, the groundwater quality issues in the basin may be exacerbated.

Growth Impacts

The 2015 IRP assumed that baseline groundwater production between 2020 and 2040 to be 91,300 AFY, which is only 750 AFY more than the current baseline amount of groundwater production. This shows that groundwater pumping is not anticipated to ramp up to meet increased demand.

Future development patterns with increased hardscaping and more efficient irrigation practices (2015 IRP) also have the potential to impact the groundwater supply. Hardscaping and increased irrigation efficiency coupled with warmer surface air temperatures, will change urban landscapes. Lawns reliant on irrigation may be converted to low-water yards of mulch, rock, shrubs, and other ground cover (CCCA LA). These changes in urban landscapes have a dual effect – one lessens the demand and the other decreases the amount of recharge from deep percolation of applied water.

Other Reliability Factors

Other factors that will impact the future viability of local groundwater within IEUA include changes in stormwater volume and timing, as well as salinity, nitrogen, and other constituent build-up in the groundwater aquifer.

Stormwater caused by surface water runoff originating from both rain and snow in the San Gabriel Mountains and locally within the IEUA service area is an important source of groundwater recharge. Future conditions for stormwater are closely related to both climate change and growth as described above. As climactic events become more extreme, it is likely that there will often be times of minimal stormwater due to drought, and other times of far too much stormwater resulting from atmospheric rivers and other extreme storm events. Additionally, increased growth in the region will likely convert agricultural or non-developed land to hardscapes, which generate more surface runoff and, consequently, stormwater.

IEUA, the CBWM, the Chino Basin Water Conservation District (CBWCD), and San Bernardino Flood Control District will need to continue cooperative management of flood control channels to capture stormwater in adjacent detention basins. Runoff not captured during these large storm events will likely reach the Santa Ana River and the Pacific Ocean, resulting in a lost opportunity to recharge stormwater flows during large storm events. The CBWM Recharge Master Plan Update (RMPU) recommended projects to increase stormwater recharge increasing the recharge capacity by 6,400 AFY (2013 CBWM RMPU). Stormwater is an extremely valuable resource to the region because it is considered “free” once the necessary facilities to capture and use this water have been constructed. It is also a high-quality water source that can improve the quality of the groundwater supplies once it has infiltrated and become blended with the aquifer (2015 IRP).

Groundwater quality in the Chino Basin has historically been impacted by high salt, nitrate, and other constituent concentrations and water quality is therefore a crucial constraint on future groundwater production. Although much of the historical agricultural land within the IEUA service area has been urbanized, agricultural operations continue to use water supplies to irrigate crops and raise livestock. Reduced rainfall and increased groundwater withdrawal may lead to more salinity buildup in topsoil and increased concentrations within the aquifer posing problems for the region's salt-sensitive crops (CCCA LA), increasing the need to secure fresh water supplies for blending or to invest in advanced treatment technologies. In addition, the CDA is an important element of the long-term salinity management strategy for the basin.

4.2.4 Imported Water

The availability of imported water supplies is heavily dependent on the regional hydrology of the SWP as well as environmental regulations. This dependency can lead to high variability in the annual amount of water available to the Southern California region. For example, during the most recent California drought (December 2011 to March 2017), the California SWP was able to supply only five percent of its contract allocation in 2013-2014, which is a significant reduction from past allocations (2015 IRP).

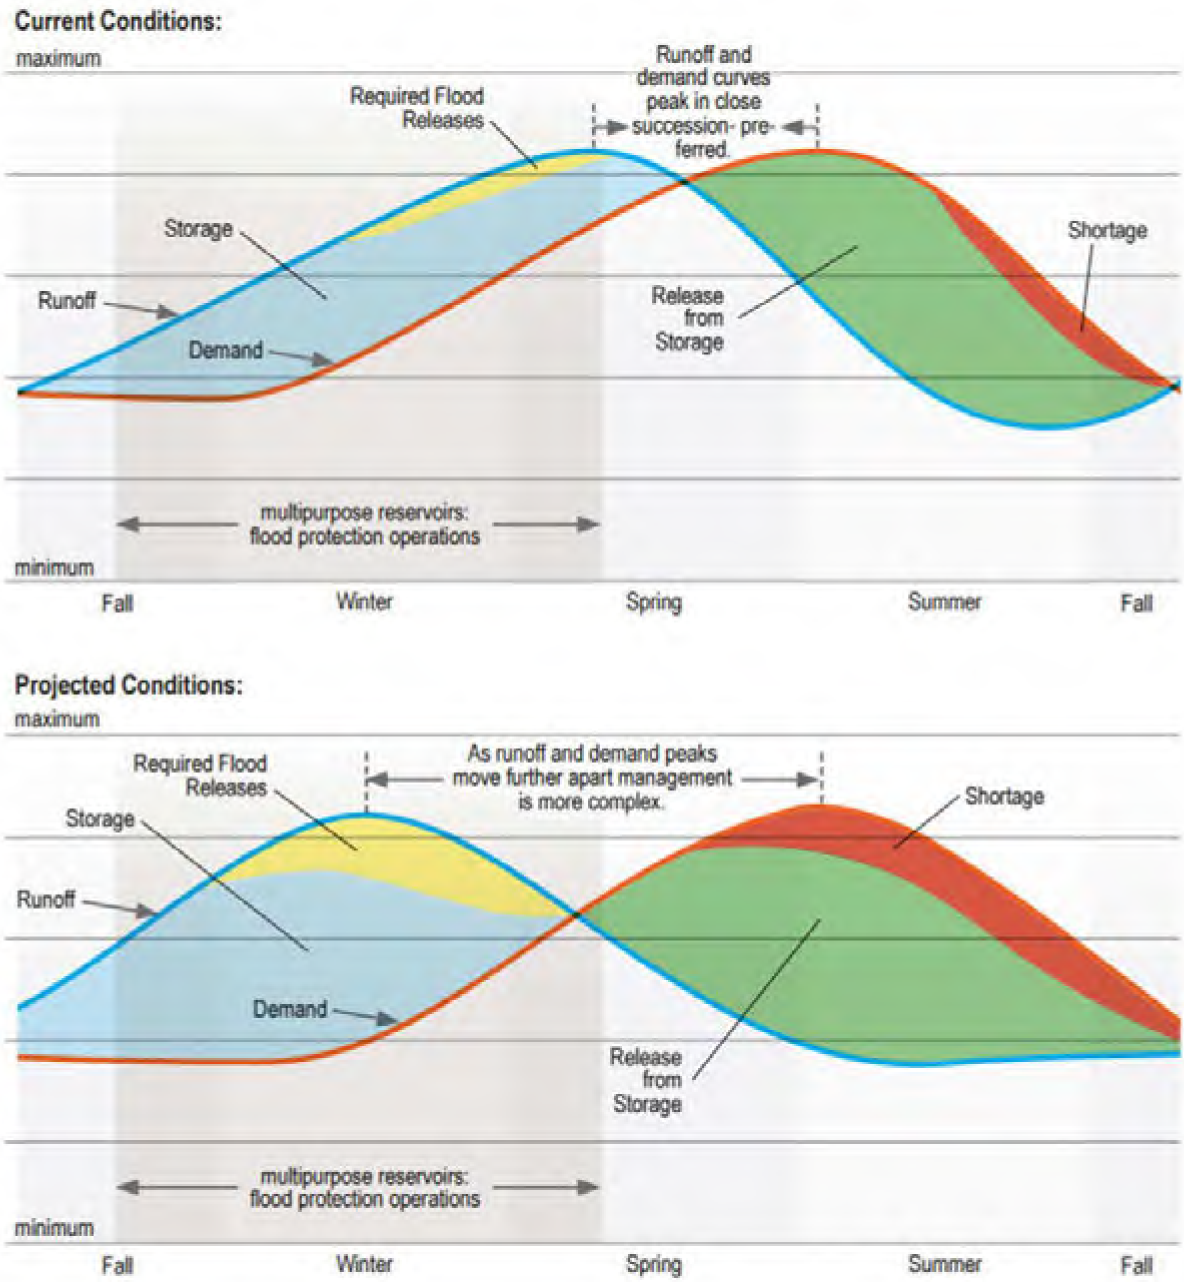
Imported water purchased from MWD is limited by a purchase order agreement. The agreement allows the region to purchase up to a total of 93,283 AFY at its lowest (Tier I untreated) rate. This limit is based on historical imported water purchases for municipal use by the member agencies and for regional groundwater recharge. The agreement includes an annual minimum purchase commitment of 39,835 AF, which is slightly less than the 40,000 AFY minimum needed to operate the region's water treatment facilities. The future of SWP supplies to MWD is uncertain, but it is projected that climate change and other factors will curtail allocations and ultimately increase the cost of water.

Future conditions for imported water are discussed below through the lenses of climate change, growth, and other reliability factors.

Climate Change Impacts

Climate change is expected to continue to significantly impact the timing and characteristics of snowpack, on which the SWP system depends. The SWP's infrastructure was designed to capture snowmelt from Sierra Nevada snowpack, and when snow melts during the warmer spring and summer months, a combination of reservoirs and conveyance facilities provides a steady water supply throughout the year. This system is particularly effective during the summer and fall seasons when water demands peak and the precipitation is limited. The reservoirs were sized based on the historical precipitation patterns, and as more precipitation falls as rain in the winter months, more water will be required to be released from the reservoirs. The challenge of the shifting snowmelt and resulting runoff patterns is illustrated in Figure 12. The reliability of imported SWP water has declined in recent years and climate change predictions appear to show further decreases in reliability.

The CCCA SWP reported that changing seasonal precipitation and flow patterns, combined with sea level rise, could result in an annual 500,000 AF reduction of Delta export as well as a roughly 25 percent decrease of north-of-Delta carryover storage by around 2060. The results also indicate that the extra runoff from early snow melting and higher percentage of rain in the winter and early spring is not conserved in reservoirs and thus cannot be used to meet the higher summer demand in the current SWP system. This extra water is released as flood water in the winter and early spring to become Delta outflow. Most climate models reviewed for the CCCA indicate that the south-of-Delta exports are anticipated to be reduced from 4 to 44 percent annually compared to historical deliveries (CCCA SWP).



Source: California Department of Water Resources

Figure 12. Changes in Runoff versus Demand for Reservoirs Dependent on Snowmelt

<u>*Growth Impacts*</u>

There are no specific challenges posed to imported supplies due to growth. The challenges associated with growth will be general in that the regional water demand increases as imported water supplies become less reliable.

Other Reliability Factors

The existing SWP infrastructure relies on the ability to pump water from the Sacramento-San Joaquin Delta where local water rights, environmental protections, and imported water conveyance are often in competition with one another. Because of these frequently competing interests and the factors described above, regulations and restrictions on Delta Exports could potentially increase in the future.

4.2.5 Recycled Water

IEUA owns and operates four water recycling plants. These facilities provide tertiary-treated wastewater, also known as recycled water. Recycled water supplies can be used for three different applications, direct non-potable uses, groundwater recharge for the Chino Basin, and other regional discharge obligations.

Recharge of recycled water is allowed by the Regional Water Quality Control Board (RWQCB) through the OBMP. In addition, the region secured several permits allowing for the direct use and groundwater recharge of recycled water. These permits define requirements for the use of non-potable recycled water, including, but not limited to, uses, water quality limits, and monitoring requirements.

The recycled water program is operated based on the following order of priorities for recycled water supply:

1. Regional discharge obligations (Santa Ana River Judgement, environmental, etc.)
2. Agency direct use demands
3. Regional groundwater recharge

Based on recent wastewater projections that were calculated as part of the Wastewater Facilities Master Plan (WFMP), treated flows are expected to increase to over 85,000 AFY by 2040. These flow estimates were based on current existing indoor water usage levels (to ensure that facilities and pipelines are adequately sized) and are consistent with the IEUA's upper demand forecast. However, indoor water use efficiency is increasing, and new plumbing code and appliance standards are being implemented. As a result, available wastewater flows by 2040 are expected to be lower than 80,000 AFY. These water flow trends are being carefully tracked by IEUA.

Because recycled water supplies, their uses, and additional source water needs are under development by IEUA and the Regional Contracting Agencies (RCAs), the DCP conservatively assumes these surplus recycled water supplies will generally be used for the purposes stated above and additional source water will be further defined by ongoing studies and reflected in IEUA's other planning efforts.

Future conditions for recycled water are discussed below through the lenses of climate change, growth, and other reliability factors.

Climate Change Impacts

The reliability of recycled water supplies is not negatively impacted by climate change. While the treatment and distribution of recycled water supplies for re-use is energy intensive, which does lead to climate change inducing greenhouse gasses, the treatment and distribution of recycled water is *less* energy intensive than imported water supplies, creating statewide reductions in greenhouse gas emissions (2015 IRP).

Growth Impacts

The volume of recycled water available to IEUA and its member agencies is dependent on indoor urban water use, which has historically steadily increased. Based on the 2015 IRP demand predictions, this trend is anticipated to continue and should provide IEUA with increased volumes of recycled water supply. However, trends in indoor water efficiency must be considered when projecting supply volume.

Current demands for recycled water include non-potable applications such as irrigation and groundwater recharge. Applications for recycled water face challenges in terms of changing wastewater quality and treatment requirements due to increases in indoor water use efficiency and outdoor water use efficiency standards and increasing regulatory and environmental requirements. Additionally, the use of recycled water is impacted by the groundwater quality of the Chino Groundwater Basin. Specifically, the applications for recycled water become constrained if the salinity in the basin rises beyond the Regional Water Board's specified limits. Maintaining and potentially expanding recycled water projects to manage these challenges will increase the resiliency of the regional water supplies. Therefore, the vulnerability of recycled water supplies diminishes with increased growth.

Other Reliability Factors

The ability to collect, treat, and reuse recycled supplies relies on infrastructure that is intertied with all the member agencies. The maintenance and continued expansion of collection pipelines, water treatment facilities, pumps, and distribution pipelines are necessary for the success of IEUA's recycled water efforts. In addition, for recycled water to be a reliable source of supply there must be a demand for the supply. Meaning that as regulations and public opinion evolves there is the potential for more, or less, demands for recycled water.

An additional factor related to recycled water use in the region is tied to the Chino Basin groundwater quality. Requirements from the Santa Ana Regional Water Quality Board and the State Water Resources Control Board necessitate ongoing implementation of regional salt management and reduction actions as a condition of the regional recycled water use permits for outdoor irrigation and groundwater recharge. The applications for recycled water become considerably constrained if it is expected that its use will exacerbate salinity issues within the Chino Basin.

4.2.6 Local Surface Water

Agencies located in the northern part of the IEUA service area have long-standing legal rights to divert and treat water from local creeks. The amount of water from these local surface supplies is variable depending on climate conditions, and currently accounts for approximately five percent of the regional water supply portfolio.

Local surface water is recognized as an important resource since the only cost to the member agencies is the operation of the facilities to capture, treat, and distribute this water. IEUA member agencies recognize the value of local surface water and are investing in the capture and treatment of these supplies.

Climate Change Impacts

Local surface supplies are dependent on precipitation and temperature, and each of these factors is predicted to be influenced by climate change, creating uncertainty from year-to-year. The predictions for precipitation in the Los Angeles/San Bernardino region, as discussed above, are still uncertain but it is expected that the extremes will be more severe, and temperatures are expected to increase.

Extreme precipitation events can result in short periods with high volumes of runoff that will be difficult to capture. Conversely, extended droughts and dry years will result in long periods without available local surface water supplies, which will increase demands on other supply types.

Higher temperatures also impact local surface water. Warmer temperatures cause more evaporation and transpiration, reducing the amount of soil moisture. This means that the soil may absorb and hold more water when rain occurs, and this can reduce the amount of water flowing into creeks and streams.

Growth Impacts

There are no specific challenges posed to local surface water supplies due to growth.

Other Reliability Factors

The ability to collect, treat, and use local surface water relies on infrastructure. The maintenance of collector pipelines, water treatment facilities, pumps, and distribution pipelines are necessary for the success of IEUA's local surface water use efforts.

4.2.7 Future Conditions Impacts by Sector

One of the major impacts to all sectors will be the new state legislation setting water use standards. On May 31, 2018, Gov. Jerry Brown signed into law two new bills that will require urban water providers throughout California to set new permanent water use targets for their service areas by 2022. Senate Bill 606 (Hertzberg) and Assembly Bill 1668 (Friedman) provide a framework for setting water use targets, as well as implementing and enforcing the new water use requirements.

While many details for implementing the new water use requirements will be determined over the next several years, the overall framework includes:

- A standard for indoor residential water use of 55 gallons per person per day— dropping incrementally to 50 gallons beginning in 2030.
- A standard for outdoor water use (to be determined) based upon and the amount of irrigable landscaped area for a residential or dedicated irrigation commercial account and the community's climate.
- A standard for water loss due to leaks in water system pipes (to be determined).

These three standards will be calculated and added together to represent an overall water use target (in gallons) for the water provider. Although some IEUA member agencies base their rates on a water budget for each customer, the new state laws do not contain water use targets for individual residents or businesses. These laws outline an overall framework to guide urban water providers in setting water use targets, which must be approved by the State Water Resources Control Board. However, urban water providers will need to determine how their service area can best achieve the new water use target.

Impact to Residential Customer Base

The residential sector represents the largest number of customers within the IEUA service area. Future conditions indicate that shortages are likely to increase due to the combination of increased population growth and added strains on water supplies. The new state water use standards will require that customers use water more efficiently.

Newer high-density housing developments will likely include indoor water use appliances and fixtures with increased efficiencies.   Residential properties with irrigated landscaping will likely be faced with more stringent restrictions on irrigation. In addition, increased average regional temperatures, and longer and drier droughts, may pose challenges with maintaining green spaces within residential neighborhoods. Lost urban greenery can further increase urban temperatures.

There will be costs associated with achieving increased efficiency both indoors and outdoors, and while there are rebates and other financial incentives offered to customers some of these costs will be placed on individual residents. Water rates may also increase as supplemental and alternative supply types and are implemented.

Impacts to Commercial, Industrial, and Institutional Customer Base

Commercial, industrial and institutional (CII) customer represent approximately 14% of water consumption in the IEUA service area. While the new laws do not set specific water use targets for CII customers, they do outline a framework for creating new water efficiency performance measures for businesses. As with residential customers, the CII customer base will be required to use water more efficiently. Impacts of future shortages to the CII sectors may extend beyond the direct reductions in water supply.

Reduced water supply will impact industries which rely more heavily on water services such as food processing and other highly water dependent manufacturing. In addition, there may be increased costs for other materials and services due to water shortages and drought conditions (i.e. energy, agriculture). As with the residential sector, water rates may also increase as supplemental and alternative supply types are implemented.

Impacts for Irrigation at Schools, Parks and Other Large Landscape Properties

Dedicated irrigation meter accounts account for almost 14% of water consumption in the IEUA service area. The demands for irrigation are likely to increase in the future due to warmer temperatures and more variable precipitation. Meeting those demands with recycled water would offer a more drought resilient supply type. Additionally, other demands for recycled water may also increase (i.e. groundwater recharge, and regional discharge obligations) as supplies become more constrained. In the event of an extreme shortage, outdoor irrigation will become a lower priority to residential and commercial uses.

4.3 Vulnerability Assessment Modeling

Investigations performed as part of the regional IRP were used to inform this DCP vulnerability assessment. As part of the IRP efforts, the Chino Basin Regional Water Supply Infrastructure Model (Model) was developed to simulate existing and future conditions of the IEUA water supplies and infrastructure. The model incorporates existing regional and local potable water demands, supplies, key regional infrastructure, and interconnections allowing the movement of water from agency-to-agency within the IEUA service area.

In June 2019, the IRP team reported the modeling results for a 2020 baseline with five scenarios reflecting various future conditions. Two of the scenarios (Scenarios 2 and 3 referred to here as “DCP scenarios”) were developed in collaboration with the DCP team with the goal of bracketing potential future drought conditions from a moderate shortage condition with some consideration for climate change, and a more severe scenario beyond what has been experienced previously but which is possible based on current trends and research.

The two DCP scenarios that were modelled are described below and illustrate a range of potential drought severity conditions:

IRP Scenario 2	IRP Scenario 3
Imported Water Shortage (Level 9 WSAP)	***Import Water Shortage (Level 9 WSAP) & Local Supply Shortage***
An isolated water shortage condition for imported water while local supplies remain relatively unaffected.	A more widespread water shortage resulting from statewide drought conditions impacting both imported *and* local water supplies, including long-term groundwater impairment.

Recent California legislation requires urban water agencies to include considerations for a five-year drought in their water supply reliability planning efforts (SB 606 and AB 1668), and Scenario 3 is a helpful building block toward compliance. The following pages summarize the assumptions and results for each of the DCP scenarios. More information on the model and other results are provided in the Technical Memo "*DRAFT Integrated Water Resources Plan Regional Water Supply Infrastructure Model TM-2: 2020 Baseline and Evaluation of Water Supply Vulnerabilities for Scenarios 1 to 5,*" dated June 21, 2019, and will be provided in the forthcoming IRP update. It should also be noted that at this stage in the modeling efforts, the interconnections and the ability to transfer water between member agencies is not enabled. Later phases of the IRP modeling effort will explore opportunities for inter-agency transfers.

4.3.1 Scenario 2: Imported Water Shortage

Scenario 2 of the IRP modeling effort is intended to simulate potential reductions in imported water supply due to future drought and climate change conditions, while also considering that local conditions may *not* be impacted to the same degree as imported supplies. The assumptions for this scenario are based on historical deliveries for imported water, member agency projections, existing infrastructure, and recent research and climate models. Key assumptions and associated datasets are described below.

Scenario 2 Assumptions

Future Demands

The projected water demands for the year 2035 were used for Scenario 2. The projected demands from the 2015 IRP were used for each member agency, which assumed three ranges for future demands based on potential water use practices and ranged from low, medium, to high (Table 2). The medium demand forecast were used for the Scenario 2 simulation.

Imported Water Supplies

In the CCCA there are numerous predictions related to future conditions in the Los Angeles/San Bernardino region, specifically related to drought and the availability of imported water. Some predictions state that south-of-Delta exports by the SWP and the Central Valley Project could be reduced by 50 percent more than during historical droughts (Wang et al., 2018). Meaning that as drought intensity and frequency increases, strains on imported water supply will also intensify beyond what has been seen in the past. The reasons for the reductions are likely to be numerous, interconnected, and complicated, but the primary causes of the increased reductions are expected to be reduced carry-over storage in reservoirs as precipitation patterns shift and sea-level rise and the resulting increased salinity in Delta exports.

This prediction is corroborated by Delta supply water quality and MWD's SWP supply availability during the drought in water years 2015-17, which provides a benchmark for future drought conditions. During this time period, the IEUA region had the lowest three-year average of imported water deliveries. See Figure 13 for historical deliveries from MWD to IEUA. Due to a low SWP allocation of 0% which was increased to 5%, MWD implemented the WSAP, and deliveries to IEUA were reduced by 41% of the supplies delivered in 2008 (the highest year in the 2000-2017 record). As a result, Scenario 2 assumed a WSAP shortage level of 9 (67.5% reduction) as a representation for future drought conditions, reflecting the CCCA's predicted deeper reductions. See Table 6 for a summary of the ten WSAP levels.

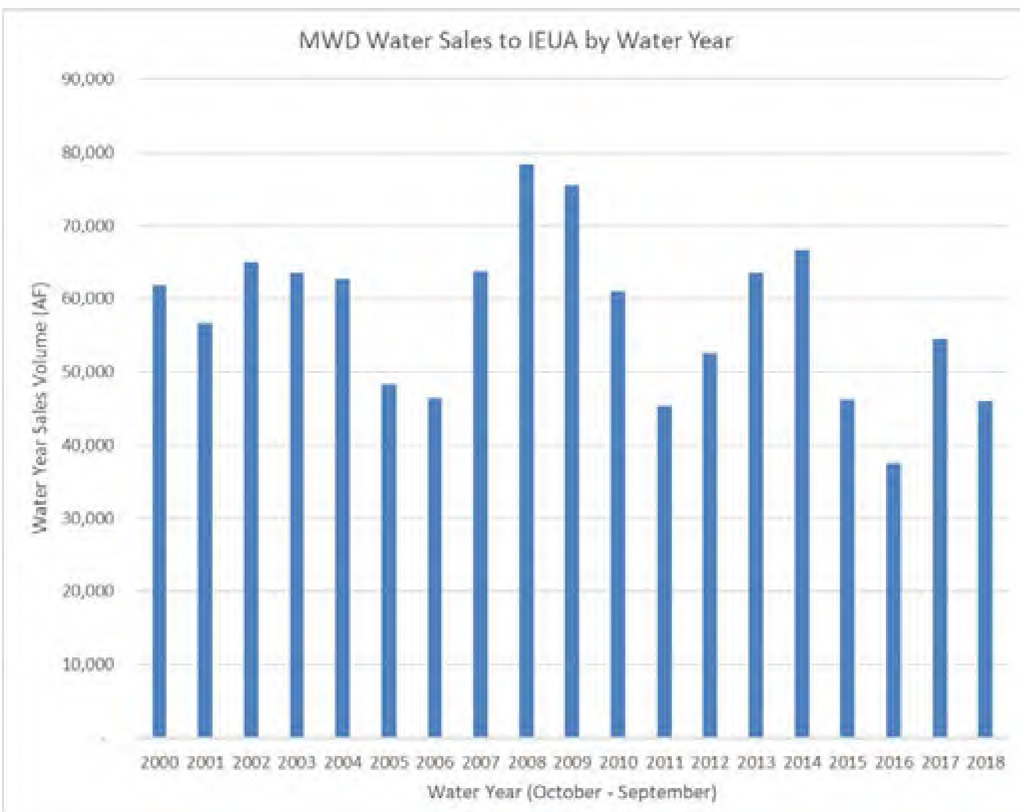


Figure 13. Historical MWD Deliveries to IEUA (Sum of Full Service and Interruptible Programs)

Table 6. MWD WSAP Shortage Allocation Index

Regional Shortage Level	Wholesale Minimum Percentage	Wholesale Reduction Percentage
1	92.5%	7.5%
2	85.0%	15.0%
3	77.5%	22.5%
4	70.0%	30.0%
5	62.5%	37.5%
6	55.0%	45.0%
7	47.5%	52.5%
8	40.0%	60.0%
9	32.5%	67.5%
10	25.0%	75.0%

Surface Water Supplies

Surface water supplies were simulated based on the 2035 projected availability as stated by each of the member agencies in their respective UWMPs. It is assumed that these supplies are unaffected by drought conditions in other areas of the State.

Groundwater Supplies

Local groundwater supplies were simulated at current available capacities and blending requirements. In addition, projected additional groundwater supplies for the year 2035 were included as reported in the member agencies' 2015 UWMPs. Details regarding how this information was collected and simulated are described in the August 2018 IEUA/INTERA Technical Memo titled *"IEUA Infrastructure Model and 2015 Baseline Scenario Results,"* and in a subsequent June 2019 Technical Memo (IEUA 2019).

4.3.2 Scenario 3: Five-Year Drought and Local Supply Shortage

Scenario 3 is intended to be representative of a severe five-year drought with a combination of shortages in imported supplies and local supplies. In a five-year drought condition, it is expected that imported water supplies would be drastically reduced as was simulated in Scenario 2 and the local surface and groundwater supplies would also be diminished. Key assumptions and associated datasets are described below.

Scenario 3 Assumptions

Future Demands

The 2035 demands from the IRP were used for Scenario 3 and are the same as for Scenario 2 (as described above).

Imported Water Supplies

The imported water supplies delivered by MWD to the IEUA service area for Scenario 3 are the same as for Scenario 2 and are set at WSAP Regional Shortage Level 9 (see Scenario 2 described above).

Local Surface Water

The local surface water supplies simulated for Scenario 3 were based on the projected supplies as reported by the member agencies in their respective 2015 UWMPs for a multiple dry year condition. In the UWMPs there was not an expected change in the projected surface water supplies from the single dry year or a multiple dry year. The multiple dry year surface water supplies were considered to be a reasonable source to represent a five-year drought condition.

Local Groundwater

In an extended five-year drought scenario, it is assumed that local groundwater supplies will be impaired due to quality as opposed to quantity. In the Chino Groundwater Basin there are trends of slowly rising TDS and nitrate levels, as well as new emerging constituents such as 1,2,3, - Trichloropropane (1,2,3 – TCP), PFOS, and PFOA, which could result in a future loss of available supply. In addition, in an extended drought scenario when other supplies like imported water are reduced, local groundwater will be relied on more heavily. Increased production from the basin could exacerbate water quality issues.

For Scenario 3, local groundwater was simulated based on current well capacities and the additional 2035 projected supplies as reported by the member agencies (as with Scenario 2). To simulate compromised groundwater quality, the wells with current blending requirements were removed from service. In addition, wells currently with noted impairment but without blending requirements, would have blending requirements of 50 percent.

4.3.3 Results

Scenario 2 Imported Water Shortage Results

The results of this modeling scenario indicate that under WSAP Shortage Level 9, three member agencies experience supply deficits ranging from 10 percent to 74 percent of 2035 demand with the current supply mix.

Other member agencies have surpluses and overall the region has a slight surplus of 2 percent of 2035 demand with current supplies, and a 10 percent surplus with 2035 projected new supplies.

The loss of imported water means that there is less water to blend, thus impacting groundwater quality. There are five agencies that use imported water for groundwater blending that would be impacted.

Scenario 3 Five-Year Drought and Local Supply Shortage Results

The results of this scenario indicate that under a severe, multi-year drought, six of the eight member agencies experience supply deficits ranging from 9 percent to 74 percent of 2035 demand with current supplies. Two member agencies have surpluses, but overall the region has a deficit of 13 percent of 2035 demand with current supplies, and 6 percent with projected 2035 supplies.

In this scenario, agencies with groundwater supplies that currently require blending lose that capacity and those with impaired supplies that do not currently require blending are impacted by a new 50 percent blending requirement.

4.4 Summary of Key Vulnerabilities

Based on the review of potential impacts to regional resources and the IRP modeling results, two key vulnerabilities are identified.

1. **Imported water will likely become less reliable in the future** and pose a considerable risk for overall regional water supply reliability. While within Scenario 2, the region showed an overall surplus, there are three agencies that currently depend more heavily on imported water and showed shortages in this situation. As Scenario 3 showed, while the region does not rely on imported water as heavily as it does local groundwater, there are ripple effects related to a loss of imported water. The loss of imported water could result in the increased reliance on local surface and groundwater sources, and increased groundwater production could cause groundwater quality issues to worsen in areas.

2. **Reductions, due to potential impairments to groundwater quality, pose the most significant water reliability risk to the IEUA service area**. All the member agencies, with the exception of SAWCo, rely on local groundwater to meet their annual demands. While groundwater has been a relatively reliable source of water in the past, conditions related to groundwater quality and reduced water available for blending may reduce the reliability of groundwater in the future. As the results from Scenario 3 illustrated, reduced groundwater quality combined with a loss of imported water could cause significant shortages for multiple agencies within the service area.

5 Mitigation Actions

Mitigation actions are projects, programs, and strategies implemented prior to a drought situation to lessen the risks and impacts of future water shortages.

IEUA and the retail member agencies developed and prioritized the list of mitigation actions through an inclusive and collaborative means as part of the IRP process. The mitigation projects were selected because they effectively address one or more of the key vulnerabilities; *future imported water supply reliability* and *ground water quality impairment*.

Both regional and local projects are included on the list. They include a combination of near- and long-term actions consisting of local supply and groundwater improvement, system interconnections, and capital improvement projects. A full list of the projects is included as an Appendix D to this document.

The timing and sequencing of project implementation is dependent on many factors. Although IEUA and member agencies will look to implementing the highest priority projects first, budget limitations and planning complexities will impact the actual timing. A lesser priority mitigation project may take precedence over a top priority one because, for example, there is outside funding available, resulting in expedited implementation.

The region is actively working on advancement of the mitigation actions included in this DCP. Through the 2015 IRP, IEUA and its member agencies explored and analyzed projects that resulted in the core recommendations discussed in this section.

This section provides an overview of the mitigation action planning efforts, strategy for mitigation action implementation, current regional planning efforts, and the context under which the actions will be advanced.

5.1 Planning Documents Utilized to Identify Mitigation Actions

Within the IEUA service area, there have been multiple planning efforts tasks initiated for the development of mitigation actions. In the early 2000s the region developed four foundational master planning documents. These historical documents illustrate how, for nearly the last 20 years, the region has recognized the increasingly uncertain future of imported water supply availability and the importance of local water supplies, particularly in changing climate conditions. As part of its response, the region has focused infrastructure investments on local water supply development strategies to reduce dependence on imported supplies and increase drought resiliency. These foundational documents are:

- Chino Basin Watermaster’s Optimum Basin Management Program (2000)

- Chino Basin Organics Management Strategy (2001)
- Recycled Water System Feasibility Study (2002)
- Wastewater Facilities Master Plan (2002)

More recently, the 2015 IRP further evaluated the resiliency of the region's water resources under future climate conditions and identified strategies for ensuring that the region's future water needs through 2040 can be sustainably met.

The 2015 IRP was considered Phase I of the IRP process and provided an extensive list of potential supply projects (both local and regional) based on regional collaboration. At the time of this DCP effort, the 2020 IRP (Phase II) is currently underway. Phase II will provide a regional implementation strategy for long-term water resource management, strategically positioning the region for funding opportunities.

5.2 Mitigation Actions Strategy

Through the existing and ongoing regional plans there has been considerable effort and extensive stakeholder engagement aimed specifically at developing mitigation-type actions to improve regional water supply reliability.

The mitigation actions identified through the IRP fall into two core strategies:

1) Invest in Local Supplies

2) Enhance Groundwater Availability

5.2.1 Invest in Local Supplies

As the availability of imported water becomes less reliable in the future, it will be ever more important to continue to invest in all forms of local water supplies, including groundwater, surface water, and recycled water. Building the local water supply capacity decreases reliance on imported supplies and improves resiliency for the regional water supply portfolio. The 2015 IRP had two major mitigation recommendations for increased local water supply capacity:

- **"Implement water use efficiency measures to decrease demand and enhance water supply resiliency."**
  Water use efficiency is universally regarded as the most cost effective method to reduce water demand and ultimately creates an additional water supply source since the water conserved can be applied to other demands.

- **"Continue investment in recycled water projects to maximize the beneficial reuse."**
  Recycled water provides one the most reliable supply types for the region. Current demands for recycled water include non-potable applications such as irrigation and groundwater recharge.

Applications for recycled water face challenges in terms of changing wastewater quality and treatment requirements due to increases in indoor water use efficiency and outdoor water use efficiency standards and increasing regulatory and environmental requirements. Additionally, the use of recycled water is impacted by the groundwater quality of the Chino Groundwater Basin. Specifically, the applications for recycled water become constrained if the salinity in the basin rises beyond the Regional Water Board's specified limits. Maintaining and potentially expanding recycled water projects to manage these challenges will increase the resiliency of the regional water supplies.

5.2.2 Enhance Groundwater Availability

Groundwater is the most heavily relied on local water supply type. The Chino Groundwater Basin provided approximately 40 percent of the regional water supply portfolio over the last decade. The vulnerability assessment for the DCP illustrated how compromised groundwater quality poses a significant threat to local water supply reliability and can be compounded as other supplies currently used for blending, such as imported water, become less reliable. Enhancing groundwater treatment and groundwater recharge opportunities will be crucial as groundwater quality issues mount within the basin and dependence on groundwater potentially increases as other sources become less reliable. Groundwater recharge with good quality water sources provides the benefits of both groundwater quality management and increased groundwater storage. The 2015 had several recommendations related specifically to groundwater recharge:

- **"Strive to acquire low TDS supplemental water to enhance groundwater quality to sustain production and reduce salinity."**
  It is important that water used for recharge helps to support the salinity management measures within the Chino Basin. Identifying and securing low TDS water will help to increase the resiliency of the local groundwater supplies.

- **"Strategically maximize the purchase of supplemental water for recharge or in-lieu when available."**
  Periods of surplus supplies from imported water, exchanges, or other sources provide an excellent opportunity to acquire additional water supplies for groundwater recharge, or to offset the groundwater demands at the time. Positioning the region in terms of awareness, finances, and infrastructure to be able to maximize the purchases of those supplies creates greater resiliency for the region's water supply portfolio.

- **"Continue to maximize stormwater recharge projects, including rainwater capture and infiltration."**
  Local precipitation in the region is highly variable seasonally and annually, and it is expected that future rain events will become more intense in terms of magnitude and duration resulting in large volumes of stormwater. Improving the regional infrastructure to capture and utilize stormwater provides a low TDS water supply for groundwater recharge.

5.3 Mitigation Action Project Evaluation

A comprehensive list of potential mitigation actions was developed through the IRP process based on numerous planning efforts, including:

- 2015 Recycled Water Program Strategy
- 2015 Wastewater Facilities Master Plan Update
- 2013 Recharge Master Plan Update
- 2015 Water Use Efficiency Business Plan
- FY15/16 Ten Year Capital Improvement Plan (TYCIP)
- Santa Ana River Conservation and Conjunctive Use Program (SARCCUP)
- 2013 Upper Santa Ana River Habitat Conservation Plan

A full list of the projects can be found in *Appendix D: 2015 IRP Mitigation Actions*.

During the IRP planning process, the Technical Work Group crafted **five water resource strategies**. Each strategy had an underlying theme to address the region's water supply vulnerabilities. Below are the five strategies:

***Strategy 1**:* Maximize Chino Basin groundwater, including prior stored groundwater.

***Strategy 2**:* Recycled water program expansion.

Strategy 3: Recycled water & conservation program expansions.

***Strategy 4**:* Maximize supplemental water supplies and recycled water supplies.

***Strategy 5**:* Maximize imported water supplies with moderate conservation.

Each of the strategies required building a mix of projects that would best meet the supply needs under the respective strategy.

In order to determine the value of each specific project, as well as its means of water supply creation, every project underwent a series of evaluation steps. First, the anticipated acre-feet yield was calculated for each of the 100 projects and, next, a determination of the number of years that it will take to yield the water.

From this, a list of the desired project outcomes was developed. These outcomes were selected because they specifically address the region's major water supply vulnerabilities. Projects were then assessed and tagged *yes, no, or neutral* on its ability to impact desired project outcomes. For example, *does the project provide increased groundwater*? *Does the project reduce TDS in the groundwater?*

These are examples of desirable project outcomes because they provide a positive contribution to local water supply.

Table 7 provides a list of the desired outcomes used as metrics to evaluate each potential mitigation action project.

Table 7. Desired Mitigation Project Outcomes

Desired Mitigation Project Outcomes	
▪ Increases groundwater storage	▪ Provides emergency local supply redundancy
▪ Increases water level in critical groundwater management zones	▪ Decreases reliance on local surface water during dry years
▪ Increases stormwater capture/recharge	▪ Reduces TDS and/or nitrates in groundwater
▪ Increases permeability or natural infiltration	▪ Decrease net energy consumption
▪ Provides additional recycled water	▪ Increases capacity for wet water years
▪ Reduces dependence on imported water during dry years	▪ Eligible for grant funding
▪ Increases local water supply	▪ Technical feasibility/ease of implementation

Once the projects were evaluated against the desired outcomes, they were uploaded into a data visualization software tool. The tool then created and compared theoretical combinations of various projects. After analysis, the tool generated the mix of projects that delivered optimum results for each of the five resource strategies developed by the Technical Work Group during the IRP planning process.

The highest performing mix of projects were selected as prioritized mitigation actions for retail agency implementation.

Although the planning process resulted in the optimal choices, actual timing and sequencing of project implementation is dependent on many factors. IEUA and member agencies will look to implement the highest priority projects first, however budget limitations and planning complexities will impact the actual timing. A lesser priority mitigation project may take precedence over a top priority one because, for example, there is outside funding available, resulting in expedited implementation.

6 Response Actions

With growing populations and the inevitability of future drought cycles, IEUA's and its member agencies' overarching goal is to create a water efficient region that can successfully withstand future water shortages without hardship.

IEUA and its member agencies have been arduously working to re-shape customers' attitudes about water sustainability and their personal role in achieving water shortage resiliency. Through education, messaging, and programs IEUA and its member agencies have been driving change, however, customers still have a way to go to fully make the transition. A percentage of customers have made significant equipment and lifestyle changes at their properties, but most have not.

Regional water sustainability can be achieved only when:

1. Customers fully understand the value of water and the unique conditions of the Inland Empire.
2. Customers create drought sustainable properties prior to emergency conditions.
3. Customers experience no water deprivation hardship during a drought cycle due to the sustainable landscape design of their properties and their water-consuming equipment.

While striving for full water efficiency is the goal, IEUA understands we're not there yet. With this knowledge, IEUA recognizes that water savings, during droughts or other water shortages, will need to be driven through an escalation in marketing, increased programs service offers, and enhanced incentives that rise as drought stages advance.

Table 8 provides a rough estimate of overall acre-feet savings necessary to meet the requirements at each drought stage. The calculations are based on the 2020 projected demand as well as single dry year and multiple year projected demands. The Acre-feet savings are calculated by using the highest percentage savings number desired for each stage. The table illustrates the need for sharp increases in incremental water savings from Stage 1 through Stage 5 during a potential future drought cycle.

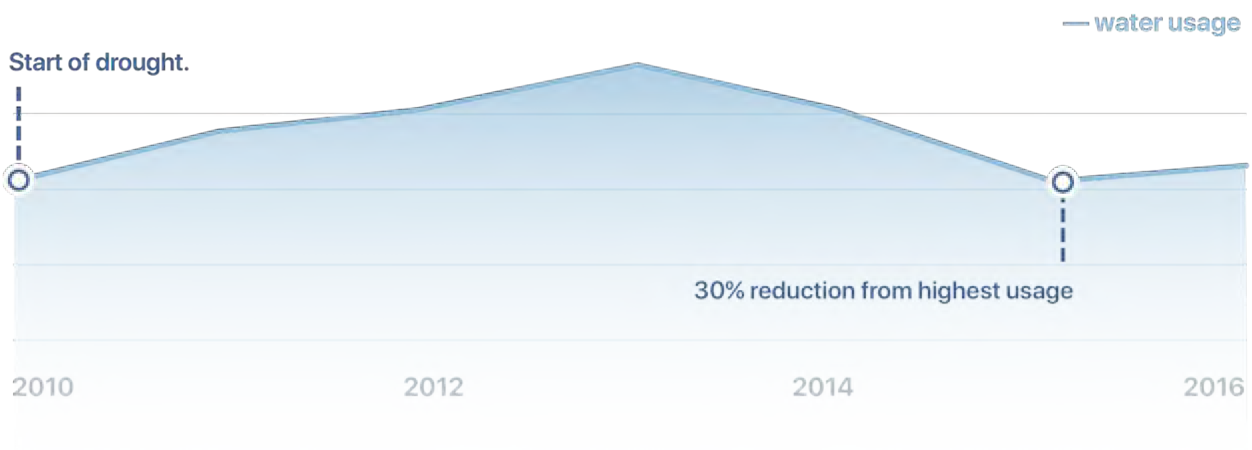
Table 8. Estimated Required Water Reduction per Drought Stage

	STAGE 1 **Est Savings (AF)** **5%** reduction	**STAGE 2** **Est Savings (AF)** **15%** reduction	**STAGE 3** **Est Savings (AF)** **25%** reduction	**STAGE 4** **Est Savings (AF)** **50%** reduction	**STAGE 5** **Est Savings (AF)** **50%+** reduction
Projected Demand	9,985	29,955	49,926	99,851	99,851+
Single Dry Year Projected Demand	10,529	31,588	52,647	105,294	105,294+
Multiple Dry Year Projected Demand	11,296	33,888	56,481	112,962	112,962+

6.1 Previous Droughts and Lessons Learned

Historical review is useful when conducting planning activities. By looking at the previous drought cycle, we see the quantity of water conserved over the course of the drought and customers' overall response time to reach reduction levels. This and other historical information were taken into account in the crafting of the Response Action Plan, as well as the Programs and Services.

The chart below provides a look-back at the annual total water usage for reporting years 2010-2016:



The take-aways that merit consideration in future planning include the following:

- Water use increased during the first couple of years of the drought.
- Customers' drought actions only reached an impactful level **late into the drought cycle,** in Year Four 2015-2016.
- Customers reacted when the situation became **extended and urgent**.
- The majority of **water savings were realized through mandatory restrictions** and water deprivation; not upgraded landscapes and efficiency equipment.
- During crisis times we need to **balance Carrots vs Sticks** in order to entice customers to make permanent changes**.**
- Today's **water usage has bounced back** to a volume above 2014 levels because the changes were not permanent.
- To drive **permanent savings** and **early response** it is desirable to have Messaging, Outreach and Programs that **Motivate vs Penalize.**

6.2 GOALS

The Response Action Plan described in the following sections, is modelled after the format of previous IEUA Water Use Efficiency Business Plans. The goals of the Response Plan are to:

- Increase the speed that drought response actions can be rolled out by pre-planning.
- Reduce workload for agencies by providing a blueprint for deployment of strategic actions as drought stages are declared.
- Provide recommendations on the optimal measures, activity levels, incentives, and services that will drive water savings according to need.
- Create an avenue for member agencies to provide input into a Regional drought response.
- Act as a starting point for creating a final plan of action during a drought event. The finalized plan may include adjustments from member agency input, new technologies, increased MWD Water District incentives, new grants, or other circumstances.

The plan is devised to balance *customer incentives and programs* with *prohibitions and penalties*. This balance between "carrot and stick" will give IEUA the flexibility to achieve quick-hit savings through restrictions, while enticing customers to move to long-term market transformation through program participation.

6.3 TYPES OF RESPONSE ACTIONS

There are a number of response actions available to IEUA agencies. These include escalation of customer messaging content and frequency, expanded outreach channels, enhanced water efficiency incentives and programs, and as necessary, water usage restrictions.

- **Messaging**
  Agencies can, and should, use creativity and attention-grabbing content to secure customers' attention and motivate them to take action.

- **Expanded Outreach**
  Customer attitudes and expectations have changed dramatically over the past decade, driven by consumers who have higher demands for expanded outreach vehicles. It's a customer-centric world and water agencies are competing for attention. This requires a modern approach to outreach including social media and influencer marketing.

- **Programs**
  Water efficiency programs provide customers with the means and guidance to lower their properties' water usage. Customer-friendly programs, substantial incentives, direct installation options and strong support services drive stronger response rates. The higher the services and incentives; the higher the customer response.

- **Restrictions**
  Watering restrictions further reduce water usage while reinforcing the message of community importance and "doing your part". They set an authoritarian tone, which can result in negative PR if the reasoning is not well communicated, however they are highly effective in securing immediate water savings and are a powerful tool for agencies.

6.4 DCP Response Process and Taskforce Operation

Once the drought monitoring framework indicates that the region has reached a specific stage of drought conditions, several actions will occur.

First, the Drought Response Taskforce will assemble.

The Drought Response Taskforce is the organizational group empowered to:

1) Create the Drought Response Plan blueprint.
2) During drought condition stages, assemble taskforce to finalize strategic response actions.
3) Work with their respective agency to implement response actions, according to plan.

The taskforce is comprised of representatives from each of the eight member agencies, and regional personnel from IEUA. The group works in a collaborative fashion to gain consensus on appropriate regional response actions.

The taskforce will make recommendations about the level of program and services, restrictions, and messaging to regional customers. These recommendations will be brought to each agency's respective management for approval.

It's important to note that, during a regional drought, an individual member agency may not be experiencing a drought condition due to their local supply mix. In this circumstance, the agency may elect in what capacity to participate in the taskforce and how to best communicate to their customers that locally there are no water supply issues, although the region is undergoing a drought stage.

Looking forwards, the taskforce will work to balance the effectiveness of regional messaging with the differing needs of individual member agencies. There are no pre-determined mandates regarding service offerings, restrictions, communications or budgets. The taskforce will collaborate on policies, while fully supporting flexibility for each agency.

The group will review the proposed actions set forth in the existing plan and make modifications as necessary. The plan was intended to be flexible and changeable. Modifications to the plan might include a change in incentive levels or program delivery mechanisms. There may also be a new water-saving technology that should be offered to customers. The taskforce might be able to secure additional grant funding, as well. Once the action plan is finalized and approved, the taskforce will implement the programs, penalties, and communications plan.

An overview of the drought response process is below:

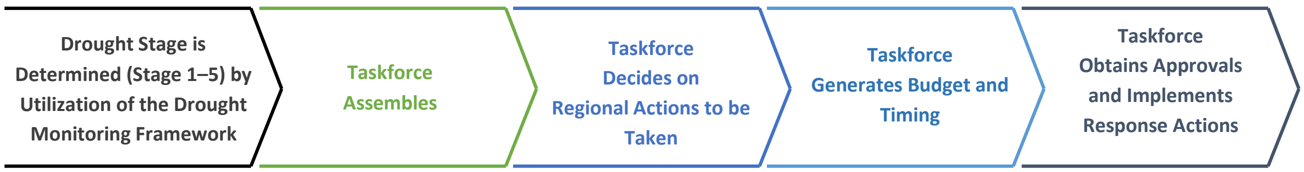


Figure 14. Drought Response Process

6.5 Response Action Plan Objectives

The objectives of the Response Plan are to integrate the drought response actions into a cohesive whole that improves the effectiveness of each component. The plan's objectives are to:

- Outline programs that are highly appealing to customers.
- Provide targeted marketing and communications for programs and restrictions.
- Guide escalation of response actions as drought stages increase.
- Allow for a consistent regional rollout that reduces customer confusion, raises response, and increases savings per household.
- Ensure communication, marketing, programs, and restrictions are interconnected and support each other in achieving water savings goals.

6.6 Response Plan Goals and Strategies

IEUA's overall goals are straightforward:

Agencies have long struggled to make significant water savings headway with high water users. To accomplish this goal, there are several strategies and tactics that must be successfully employed.

Provide Improved Target Marketing and Communications:

An essential portion of the Response Plan is deploying an effective customer marketing and outreach strategy. This is because the greatest contingency plan is worthless if the target audience is: 1) unaware of your offer, and 2) unresponsive. Retail water agency customers are widely diverse in their characteristics, desires, and motivations. The combination of regional drought messaging paired with the member agencies' individual marketing will create a stronger more unified message.

Target audiences are single family households with high water user and large landscape customers. Reaching these customers is best accomplished by first profiling and micro-targeting customers and then employing a targeted and creative messaging and outreach campaign. It has been shown that customers have a strong, positive response to respected influencers and member agencies should utilize this strategy as a part of their marketing and outreach.

Create Programs That Are Highly Appealing to Customers:

Today's customers have little patience with processes that are time consuming and complicated. Programs must be customer-friendly and provide easy access to knowledgeable individuals that can answer customer questions and guide them through difficult processes.

As experienced in the previous drought cycle, customers are motivated by generous incentives or direct installation services that make it worthwhile to commit their valuable time and resources to a program.

Scalable programs allow customers to participate with relative ease, avoiding long processing times and capacity limitations for customer sign-ups.

Reach Higher Water Savings:

As drought stages escalate, there is an ever-increasing need to "dig deeper" and reach a higher level of water savings per site.

To accomplish this, tactics need to be escalated to higher levels. This includes the deployment of customer communications that contain a heightened level of urgency and at increased intervals. It also means that restrictions and penalties must be increased, as well.

6.7 Strategy Per Drought Stage

Tactics will expand as drought stages escalate. Agencies will increase staffing capability, add more customer support, and provide a higher level of program incentives and services as increased drought stages are declared.

At Stage Zero, a non-drought stage, programs and incentives will continue to be offered to customers at standard levels. During this time, the goal will be to encourage and incentivize customers to create drought sustainable properties in advance of an emergency. The focus will be on turf replacement programs and customer education offerings.

Once a drought enters a specific stage, the taskforce will assemble to finalize the Response Plan for that stage and begin the implementation process for customer targeting and increased outreach.

At **Stage 1 (1-5% decrease),** the plan is to profile customers and micro-target high potential customers, utilizing messaging that will best resonate with those customers.

The strategic focus for **Stage 2 (6-15% decrease)** is to expand activity for irrigation equipment direct installation programs and ramp up influencer marketing.

Tactics for **Stage 3 (16-25% decrease)** require incentive increases for landscape and irrigation measures and an expansion in outreach to customers.

Stage 4 (26-50% decrease) requires IEUA and its agencies to heighten the message of urgency and put forth a community call to action. Additionally, there will be an increase in penalties, implementation of emergency alerts and expanded news media coverage.

During **Stage 5 (water use for essential functions only),** only indoor plumbing and property leak detection programs will be offered. All landscape & irrigation programs will be suspended and IEUA will implement crisis messaging, announcing water for essential use only.

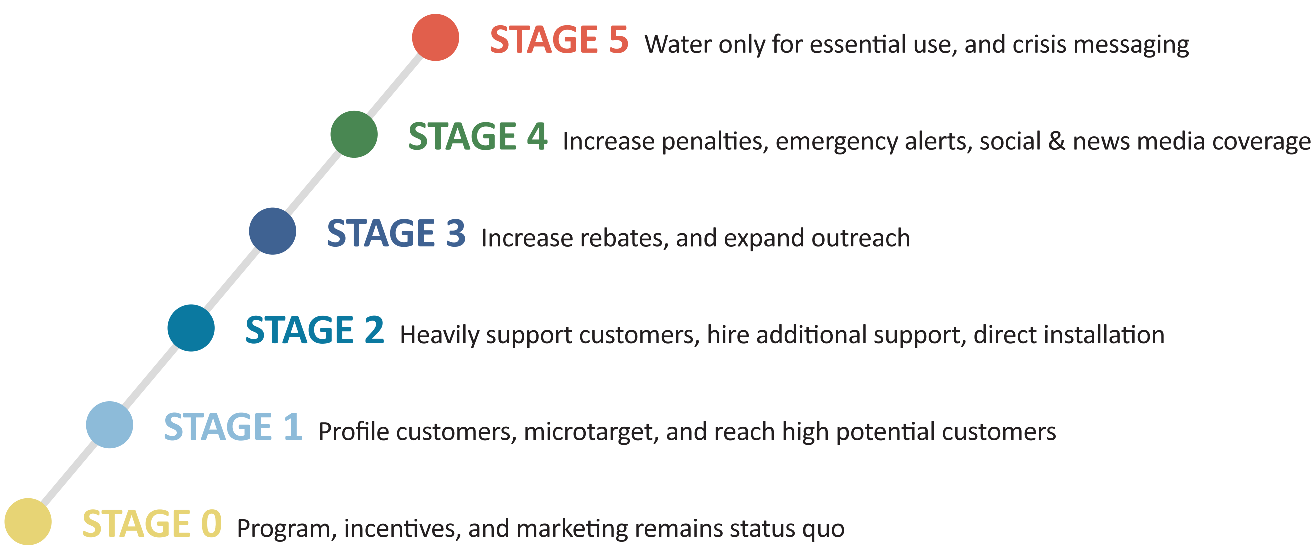

Figure 15. Drought Stage Strategy

6.8 Selected Programs and Services

There are numerous water-saving programs being offered to customers throughout the U.S. today. IEUA and its member agencies selected programs that best meet the needs of the Inland Empire during the next drought cycle.

These programs were selected because: *First*, they target the highest water savings opportunity which is outdoor water usage, and, *Second*, each program is fully scalable to meet escalating needs.

A scalable program Is designed to expand or contract *with ease* for the purpose of aligning with changing circumstances. This is particularly important during escalating drought stages where water agencies have an urgent need to drive increased participation and water savings.

A scalable program typically has mechanisms that can be ratcheted up or down without unbearable stress to the operating organization. Rebate programs are perhaps the most scalable incentive offering. Response can be driven up by increases in incentives and decreases in the complexities of program requirements. A scalable program has 1) market potential, 2) market readiness and 3) market momentum. Each of these has following characteristics:

Market Potential

- Large universe of potential customers
- A high potential for total water savings

Market Momentum

- Customers are interested
- Saturation is on the upswing

Market Readiness

- Sound technologies & solutions that are "tried and true"
- Technologies & solutions are readily available to customers

IEUA and the member agencies, through the plan development taskforce process, identified and selected seven programs and three support services as having the highest market potential, readiness and momentum.

The response programs are described below:

Table 9: Selected Programs

PROGRAMS	DESCRIPTION
Turf Replacement Incentives	$3 per sq. ft. incentive level for turf replacement.
Residential Irrigation Tune Up	Irrigation repairs, nozzle installations, and controller programming provided at no cost to the customer.
Residential Smart Irrigation Direct Installation	Customers receive installation of nozzles, controllers, and flow sensors.
School Smart Irrigation Direct Installation	Provide schools with installation of spray heads, nozzles, and controller programming.
FreeSprinklerNozzles.com	Online ordering and mail delivery of high efficiency nozzles.
Qualified Contractor Smart Irrigation Incentives	Provide approved contractors incentives for nozzles, controllers, drip, and flow sensors.
Home Leak Detection	Provide an incentive for a home leak detection device.

SUPPORT SERVICES	
Landscape Surveys	Provides homeowners with water savings recommendations and links to programs.
Landscape Workshops	Provides instruction on turf replacement & maintenance.
Landscape Design Services	Provides customers with help regarding irrigation system layout, plant selection, soil considerations, and overall design for their WE landscape upgrade project.

Recognizing that the future is unknowable, IEUA understands that unforeseen marketing and water savings opportunities may present themselves at some point during a drought cycle. For this reason, it is recommended to implement a mechanism to fund new, creative approaches or temporary resources.

This plan includes the creation of the WEFlex program which would offer IEUA's retail agencies funds for locally administered activities. The budget would be allocated to each agency based upon the water agencies size (or water sales). An agency could use the funds for local activities such as water waste enforcement and education or recycled water hook ups and permit fees. New technologies or other programs and services could be funded through WEFlex Fund, if approved by the drought response taskforce.

An agency will submit a description of the local activity, estimated costs and potential benefits or results. When accepted, the response taskforce will allocate the funds.

Program and Service Ranking by Drought Stage

Each of the selected programs was ranked by agency representatives to determine its viability during each advancing drought stage. The selection process for these programs and services was conducted by having agency representatives individually rank viable programs as a high (3 points), medium (2 points), or low (1 point) at each respective drought stage level.

This ranking criterion was based on the level of feasibility, appropriateness, and overall impact provided by that program/service at each drought stage. Budgets and program scalability were additional considerations factored into the ranking process. The group also assessed the effect and motivation that escalating drought stages would have on customers and how that, in turn, might drive customers' response for each program/service.

The results were totaled and averaged for each program at each drought stage. Higher numbers reflected a greater expected effectiveness for that program or service. Lower numbers indicated reduced support for the program or service and less likelihood for inclusion in the list of program offerings.

It's important to note that the ranking process provides general consensus and structure for planning, but program ranking is fluid and, as circumstances evolve in the future, the selections and priority levels may change.

Using the high, medium, or low point rubric program rankings were compiled and recorded as shown in the chart on the following page.

	STAGE 0	STAGE 1	STAGE 2	STAGE 3	STAGE 4	STAGE 5
PROGRAMS						
Turf Replacement	1.71	1.86	2.14	2.43	2.71	2.71
Residential Irrigation Tune Up	2.00	2.14	2.43	2.29	2.43	2.43
FreeSprinklerNozzles.com	1.83	1.71	2.00	2.00	2.57	2.57
Qualified Contractor Smart Irrigation Incentives	1.67	1.67	1.67	1.86	2.29	2.29
Residential Smart Irrigation Direct Installation	1.57	1.86	2.14	2.43	2.57	2.57
School Smart Irrigation Direct Installation	1.80	2.20	2.17	2.43	2.57	2.71
Home Leak Detection	1.33	1.33	1.71	1.86	2.43	2.57
SERVICES						
Landscape Surveys	2.00	2.00	2.20	2.00	2.60	2.40
Landscape Workshops	2.00	2.00	2.14	2.43	2.57	2.57
Landscape Design Services	1.57	1.71	1.86	2.14	2.43	2.57

Figure 16. Program Evaluation per Stages

As is shown, generally, the higher the drought stage, the higher the level of program services to be provided by agencies. The reasoning for this is common-sense. Agencies need heightened customer response and they are much more likely to participate in a program when they are provided with free installation and low-cost product or, as with turf incentives, the rebate level is enticingly high.

At each drought stage, it is anticipated that the highest-ranking programs will be those most actively promoted, and those offering attractive customer enticements to participate.

As stages escalate, agencies are prepared to ramp up activity for all programs, but will rely most heavily on Turf Replacement, FreeSprinklerNozzles.com, and direct installation of landscape measures. The number of home surveys, workshops, and design services will also increase.

Home Leak Detection was ranked as the lowest priority program during Stage 0 and Stage 1, and only ramps up significantly in the later drought stages.

It's important to reinforce that the program and services rankings are not absolute and are a suggested template to be adjusted according to circumstances that exist at each actual drought stage.

Actual incentives, services, and roll out schedules will be determined by the taskforce, when the drought stage is declared, and the group is assembled.

6.8.1 Program Cut Sheets

IEUA and its member agencies collectively has selected seven customer programs to be offered during drought conditions. Each program is detailed in an individual write-up contained in Appendix E.

The components of each cut sheet are explained in the diagram on the following page. Following the guide is an example of a program cut sheet for the Turf Replacement Program.

Program Cut Sheet Guide

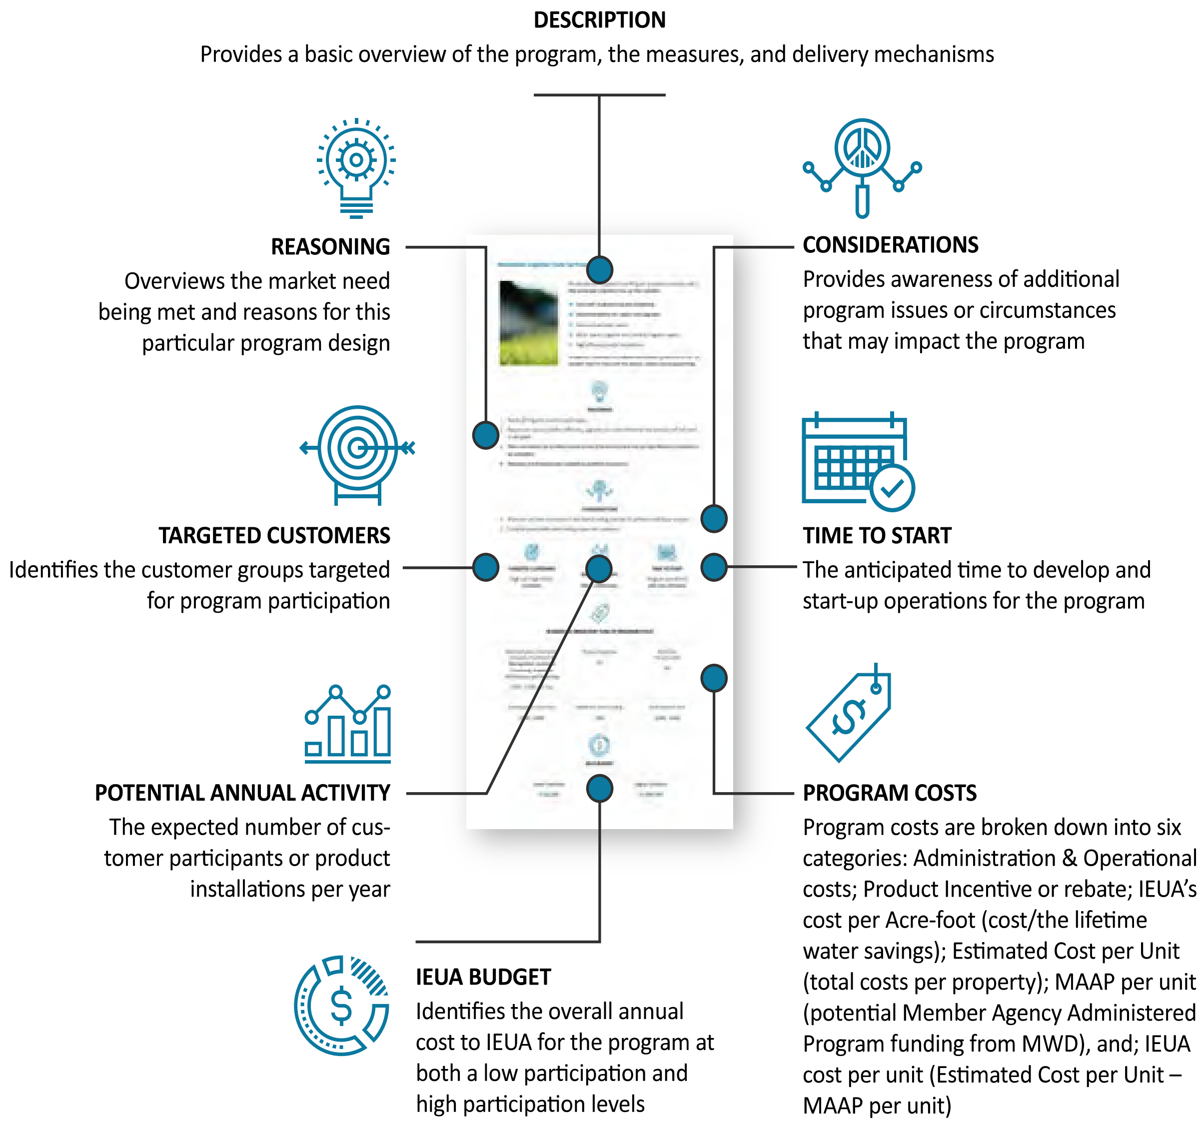

Figure 17: Program Cut Sheet Guide

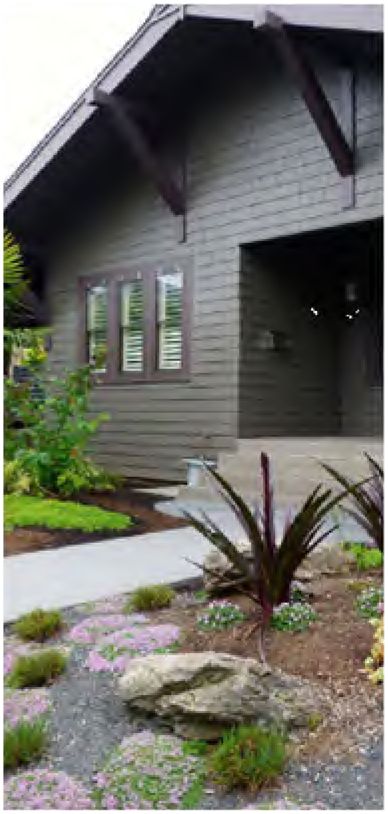
PROGRAM CUT SHEET EXAMPLE- TURF REPLACEMENT PROGRAM

Turf Replacement Program



The Turf Replacement Program encourages customers to remove high water-consuming turf and replace it with alternative solutions such as low water-using, regionally appropriate plants and surfaces that allow for ground water infiltration and elimination of runoff. Qualifying applicants are eligible to receive $3 per square foot of turf removed with a maximum incentive of 5,000 square feet for residential customers and 50,000 square feet for commercial customers. Eligible projects must have:

- Three plants per 100 square feet of area transformed
- No hardscape within the transformed area, except permeable hardscape
- A stormwater retention feature
- Replacement or modification of overhead spray sprinklers

For reference, the historical program activity of square feet removed is listed below.

	Residential	Commercial	Total
FY 14/15	119,130	1,136,334	1,255,464
FY 15/16	1,596,789	3,337,120	4,933,909
FY 16/17	255,091	637,916	893,007

REASONING

1. There are hundreds of thousands of square feet of irrigated turf in the IEUA territory.
1. Replacing turf with regionally appropriate plants aids in transforming the market. In a recent analysis done by Western MWD, for every customer replacing their turf, another customer did so without an incentive.
2. Provides long term savings- Current studies have shown that savings increase after the initial plant stabilization period and persist over 10 years or more.

CONSIDERATIONS

1. Turf replacement has an extremely high cost per acre-foot.
1. The market acceptance is low during non-drought times.
2. There are numerous customer barriers: costs, concerns about the new look, and lack of ability to execute projects.
3. Contractors are not interested in projects smaller than 1,000 sf.

TARGETED CUSTOMERS	POTENTIAL ANNUAL ACTIVITY	TIME TO START
All customers with live turf	500,000 – 5 Million SF	Currently operational

TURF REPLACEMENT PROGRAM COSTS

Administration, Contractor Outreach, Enrollment & Management, Incentive Processing, Inspection Verifications, and Reporting	Product Incentive	IEUA Cost Per Acre-foot
Covered by Metropolitan through regional vendor	$3 per square foot	$769 ($ per sf)
Estimated Per Unit Cost	MAAP Per Unit Funding	IEUA Cost Per Unit
$3 per sf	$2.00 (regional rebate)	$1 per sf

BUDGET

Lower Incentive	Higher Incentive
$500,000	$5,000,000

Figure 18. Sample Cut Sheet – Turf Replacement Program

6.9 Messaging and Outreach

If you don't nail the messaging and outreach, the programs are meaningless.

Communication and outreach play a crucial a role in the delivery of water savings as the programs themselves. A strong plan will ensure that IEUA reaches the target audience, boosts awareness, and ultimately, delivers water savings.

For this reason, the Response Plan communications need to:

- Be heard by the right customers, understood, and favorably received.
- Clearly inform the customer of the current stage, tell them what action is desired, and motivate them to respond to the request.

Ultimately, all forms of communications and outreach need to work together throughout the region to raise response and increase water savings per household.

6.9.1 Requirements for An Effective Message and Campaign

The key principle of a successful outreach and communications campaign are:

1. Know Your Customer
2. Get the Message Right
3. Craft an Outreach Plan that Drives Customer Response

Know Your Customer

An organization needs to understand what each customer wants and then provide the I-can't-say-no-offer. Companies experience much higher response rates when they understand and effectively respond to customers' desires.

This requires data analysis, creation of customer personas, and micro-targeting to particular groups of customers. There are numerous analytics programs available today that will help agencies to identify distinct customer groups and personas. By knowing this, IEUA can target market services and program offers with intelligence and precision. Statistics show that micro-targeting greatly boosts customer response. For IEUA, this converts to higher water savings as well.

Get the Messaging Right

Marketing campaigns are most successful when they evoke emotion and resonate with a human need.

An emotional message strategy uses feeling to sell – and this is a much more powerful motivator than logic. An outreach vehicle using this tactic will make the target audience feel an emotional connection to the agency, program, water efficiency measure, and/or call-to-action.

IEUA will need to utilize the following messaging strategies to garner interest and participation from customers:

- *Emphasize the benefits* - What does this particular customer need? Present a solution to their problem.

- *Keep it simple.* - A confused mind says "no." People worry that deceit is hidden amongst the complexity.

- *Make it Fun* - Draw customers in by using fun and catchy messaging, stories, eye-catching visuals, and humor.

- *Use Authority*- Influencing others is easier if customers view the person making the pitch as an authority figure. We all like to listen to and follow an expert. We trust that they know what they're doing.

Two Types of Messaging Required

There are reasons for creating and driving mass audiences through broad messaging and other reasons for targeted action messaging directed to specific audiences. IEUA will need to provide both types effectively during drought conditions.

1. **Broad Messaging:** Broad messaging (delivered via news stories, radio/tv ads, billboards, etc.) gives the widest reach and allows IEUA to communicate overarching messages including:
    - Water Scarcity Issue
    - Urgency to Act
    - Commitment to continue to provide safe, reliable water supply

2. **Targeted Action Messaging:** Targeted action messaging is typically aimed at specific groups of customers, those most likely to respond to your request for program participation or water-use reduction. To promote action, IUEA and the member agencies will need to create messaging content and outreach such as below:
    - Design messaging to motivate landscape changes for single family customers
    - Post success stories – community members, people of prominence, business leaders
    - Promote stories from micro-influencers – Q&A blogs with customers, homeowner success stories, Did-You-Know educational snippets
    - Utilize 3rd party influencers – these individuals are more trusted than a company itself
    - Create a community call to action – "your community needs your help" messaging

Craft an Outreach Plan that Drives Customer Response

Successful outreach campaigns utilize the following strategies:

- Profile your customers to understand each customer's persona
- Micro-target to prospect the right customers for each offer
- Incorporate your strong messaging and influencer authority figures in all offers
- Add personalization
- Demonstrate value and generous offer
- Include a call to action
- Make it easy for customers to say YES
- Follow up and
- Track results
- As stages advance, increase frequency, urgency and intensity

IEUA and its agencies will need a creative and dynamic plan in order to increase customer response and water use reduction, especially during the higher stages.

It's important to note that most agencies still utilize antiquated marketing techniques, with little-to-no market research, standard messages and rudimentary outreach methods.

6.9.2 Successful Outreach Methods

There are major outreach mechanisms to be utilized for general categories of customers. Each outreach approach should be personalized to the group being targeted.

- Direct outreach to high users via personalized means (phone, letter, email, etc.)
- Regional outreach through broad media channels
- Earned media
- Social media
- Grassroots and community outreach

6.9.3 Importance of Influencers & Relationships

It's important to reiterate the essential need for influencers. Influencers are trusted individuals who have a large audience and can reach across media and social platforms. Because of their high level of trust-ability, they're often able to persuade (or "influence") readers and viewers to purchase products or endorse causes that they promote.

Influencer marketing is a highly effective way to reach interested customers and dramatically increase response. They act as a trusted and respected “friend” and customers trust third party influencers more than a company itself.

Who’s Prominent in the Inland Empire:

- Well known business owners/leaders
- Local sports or entertainment figures
- Respected church leaders
- Active PTA parents
- High profile community organizers

6.9.4 Drought Outreach Matrix

Communications and urgency increase as drought stages escalate. Since customers are the means to the water-savings solution, it’s imperative that they understand each drought stage and what’s required of them. Quality messaging will clearly communicate the current drought stage, define the condition, request a desired customer behavior, and direct them to solutions.

An overview of Drought Outreach per Stage is provided on the following pages.

<table>
<tr><th>Stages</th><th>0</th><th>1</th><th>2</th><th>3</th><th>4</th><th>5</th></tr>
<tr><td>Messaging</td><td>Overall preparedness and drought resiliency. Drought will be a regular occurrence.</td><td>What Watch Condition Means</td><td>What Warning Condition Means</td><td>What Emergency Condition Means</td><td>What Critical Condition Means</td><td>What Catastrophic Condition Means</td></tr>
<tr><td>Desired Behavior</td><td>Get customers to install drought resilient landscapes & smart irrigation prior to the next drought.</td><td>Minimum 1-5% decrease in water use</td><td>Minimum 6-15% decrease in water use</td><td>Minimum 16-25% decrease in water use</td><td>Minimum 25-50% decrease in water use</td><td>Water used for only essential functions</td></tr>
<tr><td>Outreach Strategies</td><td colspan="6">Evaluate your specific community and the customers in your service territory to determine a compressive plan using a combination of the following strategies and tactics. Each approach should be personalized to the group you are targeting.
☐ Direct outreach to high users
☐ Regional outreach through broad media channels
☐ Social media outreach
☐ Grassroots and community outreach</td></tr>
<tr><td rowspan="3">Tactics</td><td colspan="6">☐ Social media toolkit for community influencers
☐ Grassroots training program for community groups, local organizers and high school students to share messages in their community (includes toolkit)</td></tr>
<tr><td colspan="2">☐ Fact sheet describing each stage, the meaning and the impact to both current landscapes and drought resilient landscapes</td><td colspan="4">☐ Fact sheet describing the stage level and how that impacts customers – one per stage with need action for each level
☐ Social media posts with messages and steps for how customers can respond to the appropriate stage
☐ "How to respond" fact sheet for each stage</td></tr>
<tr><td colspan="2">☐ Case studies and feature pitches of successful landscape transformations (videos telling the stories, write-ups and photos)
☐ By-line articles by local influencers placed in local publications</td><td colspan="4">☐ News release about stage and actions that need to be taken</td></tr>
</table>

Stages	0	1	2	3	4	5
Tactics (con't)	☐ General informational flyers about drought resiliency and sustainable landscaping		☐ Website ☐ Bill inserts ☐ Social media reminders (some promoted posts)		☐ Wireless Emergency Alerts ☐ Personal Localized Alert Network ☐ Website ☐ Social Media

Figure 19. Drought Outreach Matrix

6.10 Voluntary and Mandatory Restrictions

Both voluntary and mandatory restrictions are coupled with public education campaigns to provide customers with information about the purpose for the restriction(s) and the call-to-action. Restrictions are typically highly publicized through local media, web pages, social media, mailings and water bills.

Mandatory restrictions are a more effective tool for drought coping than voluntary measures; however, mandatory restrictions can create heightened negativity directed at the customer's water provider.

Common restrictions include partial or total prohibitions against using hoses to wash paved areas, limits on car washing and filling or refilling swimming pools, and restrictions on watering times.

As drought stages are declared, each agency will implement voluntary and mandatory restrictions as dictated by their respective Water Waste Ordinance. It's important to note a couple details:

1. Each ordinance is unique to a specific water agency and the ordinances differ slightly from one another.
2. Ordinance stages are locally declared and therefore may not align with other agencies or a regionally-declared stage.

Table 10. Water Waste Ordinance by Agency

Agency	Ordinance/Code Title
City of Chino	Municipal Code Water Conservation 13.-5.010 – 13.05.120
City of Chino Hills	Ordinance 300u
Cucamonga Valley Water District	Ordinance 2019-5-1
Fontana Water Company	San Gabriel Valley Water Company Rule No. 14 & Schedule 14.1
Monte Vista Water District	Ordinance 22
City of Ontario	Municipal Code Water Conservation Plan Title 6, Section 8A
City of Upland	Municipal Code 13.16.020 & 13.16.05.050

Each agency is responsible for locally enforcing the ordinance, although enforcement is difficult to maintain. In order to accomplish this, agencies have to add field staffing, deal with administration of the water waste ordinance, and handle the increased level of customer phone calls.

Enforcement is critical to the integrity of the ordinance in the past and remains so for future water shortages. Without action and penalties, the ordinance has no teeth and customers soon recognize this thus nullifying the effectiveness of the initiative.

Typically, violations are reported by community members or visually seen by agency staff. Enforcement staff will then send letters, visit customer properties and educate customers on the importance of adherence for both the resident and the overall community.

The new WEFlex Fund (full description can be found in Appendix E. Response Action Program Cut Sheets) will be available to support agencies' enforcement costs. An agency will be required to present their plan and budget to the taskforce for approval of funds.

Below is a snapshot of each agency's water waste ordinance at respective stages as designated by that agency. As can be seen, not every restriction is required by every agency. Absence of a restriction is shown on the chart by a white square.

6.10.1 Restrictions by Agency

	Chino	Chino Hills	Ontario	Upland	CVWD	Fontana	MVWD
No irrigation run off	Stage 0	Stage 2	Stage 1	Stage 0	Stage 0	Stage 1	Stage 0 (BP)
No irrigation more than 10 minutes						Stage 1	

	Chino	Chino Hills	Ontario	Upland	CVWD	Fontana	MVWD
No irrigation more than 15 minutes	Stage 0	Stage 2					Stage 0 (BP)
No irrigation from 10am - 6pm				Stage 0			
No irrigation from 9am - 4pm					Stage 1		
No irrigation from 9am - 5pm						Stage 1	
No irrigation from 8am - 8pm							Stage 0 (BP)
No irrigation from 6am - 8pm	Stage 0		Stage 1 (6am-6pm)				
Irrigation only every other day	Stage 2			Stage 1 based upon address			
Irrigation only 2 days per week	Stage 1 4pm - 9am			Stage 2 based upon address			
Irrigation only one day per week				Stage 3 based upon address			Stage 2 Saturday only
Irrigation three days per week between 6pm - 6am; based upon address odd/even		Stage 2					
Irrigation two days per week between 6pm - 6am; based upon address odd/even		Stage 3					
Irrigation two days per week between 4pm - 9am; based upon address odd/even			Stage 2				
Irrigation only on Tuesday and Saturday							Stage 1
Irrigation only three days per week - Tues., Thurs., Sat.							Stage 1
Irrigation only 3 days per week depending upon street address						Stage 1	
Irrigation only 2 days per week depending upon street address						Stage 2	
Irrigation only 1 days per week depending upon street address						Stage 3	
No landscape irrigation		Stage 4	Stage 4			Stage 4	

	Chino	Chino Hills	Ontario	Upland	CVWD	Fontana	MVWD
Irrigation shall not exceed 75% of the amount of water used during the same billing period							Stage 1
Irrigation shall not exceed 50% of the amount of water used during the same billing period							Stage 1
Irrigation shall not exceed 33% of the amount of water used during the same billing period							Stage 2
Irrigation only every other day - May 1 - Sept 30	Stage 1						
No irrigation on rainy days	Stage 0	Stage 2 1/10" or more within a 48 hour period					Stage 0 (BP)
No irrigation during and for 48 hours after measurable precipitation		Stage 2			Stage 0	Stage 1	
No irrigation on turf areas public street medians					Stage 6	Stage 2	
No irrigation of landscapes outside newly constructed homes and buildings					Stage 6	Stage 2	
No washing down pavement	Stage 0	Stage 2	Stage 1	Stage 0 if runoff otherwise Stage 3	Stage 0 can use water broom	Stage 1	Stage 0 (BP) with waterbroom
No excess use - breaks and leaks	Stage 0	Stage 2 repair within 48 hours	Stage 1	Stage 0	Stage 0	Stage 1 repair within 48 hours Stage 2 repair within 24 hours Stage 4 repair immediately	Stage 0 (BP) within 7 days
No washing vehicles without bucket or shutoff nozzle	Stage 0	Stage 2	Stage 1	Stage 0	Stage 0	Stage 1	
Restaurants prohibited to serve water - except upon request	Stage 0	Stage 2	Stage 1	Stage 0	Stage 0	Stage 1	
Water fountain or feature without recirculated water prohibited	Stage 0	Stage 2	Stage 0		Stage 0	Stage 1	

	Chino	Chino Hills	Ontario	Upland	CVWD	Fontana	MVWD
Hotels/motels laundering sheets/towels everyday - except upon request	Stage 2	Stage 3		Stage 0	Stage 0	Stage 1	Stage 0 (BP)
No leaving water running while brushing teeth, shaving, soaping, shower or washing dishes						Stage 1	
Commercial car wash not using recirculated water	Stage 0		Stage 0	Stage 1 Also coin-op laundry			Stage 0 (BP)
Single-pass cooling systems	Stage 0		Stage 0				
New cooling towers, decorative fountain and car washes must have reuse system							Stage 0 (BP)
Industrial customer must evaluate their processes for ways to conserve water					Stage 0		
Restaurant using non-conserving spray valves	Stage 1						
Ornamental lakes/ponds filling or refilling - except to sustain aquatic life	Stage 1		Stage 1	Stage 1		Stage 3	
Filling or refilling pools only allowed from 4pm - 8am						Stage 1	
All decorative fountains and pools (non-swimming) shall be drained		Stage 4					
Irrigation of golf course fairways prohibited				Stage 1			
No use of water from fire hydrant other than fire fighting		Stage 2	Stage 1	Stage 1		Stage 1 allows utility maintenance	Stage 1
No vehicle washing except on designated outdoor water use days - Midnight - noon after sundown				Stage 1			
Only fill pool on allowed odd/even irrigation days		Stage 2	Stage 2				
Nurseries, golf courses and other water dependent industries only allowed to irrigate every other day			Stage 2				
No new meters - unless already permitted or to protect public health	Stage 3					Stage 4	

	Chino	Chino Hills	Ontario	Upland	CVWD	Fontana	MVWD
No commitments shall be made to provide water service as part of new land use entitlements		Stage 4					
Nurseries, golf courses and other water dependent industries only allowed to irrigate every third day			Stage 3				
No installation of new landscapes							Stage 2
No water used for construction and dust control		Stage 3 if recycled water is available			Stage 8		Stage 2
No vehicle washing				Stage 3			Stage 1
Nurseries, golf courses and other water dependent industries only allowed to irrigate with handheld			Stage 4				
No non-essential water use i.e. filling pools			Stage 4	Stage 1			Stage 1
				Stages are not numbered: Year round, Moderate shortage, High shortage	*Stages provide ability to mandate % reductions*		*Stages are not numbers: Best practices, Significant shortage, Critical, Emergency*

Figure 20. Water Waste Restrictions per Agency

6.11 Staging Strategy

As drought levels increase, more effort is required from agency customers.

This will happen only if IEUA and member agencies are effective in their mission to reach the right customers and provide the necessary incentive and support.

- Early profiling and micro-targeting of customers will provide great benefit in reaching the right customers, especially as drought stages escalate.
- Stage-by-stage increases in direct installation services, incentives, and penalties will drive higher water savings.
- Clear and frequent communications with customers is required at each stage to inform and motivate.

Below is a recap of the suggested strategic actions to be taken at each drought stage:

The Blueprint for Deployment of Strategic Actions

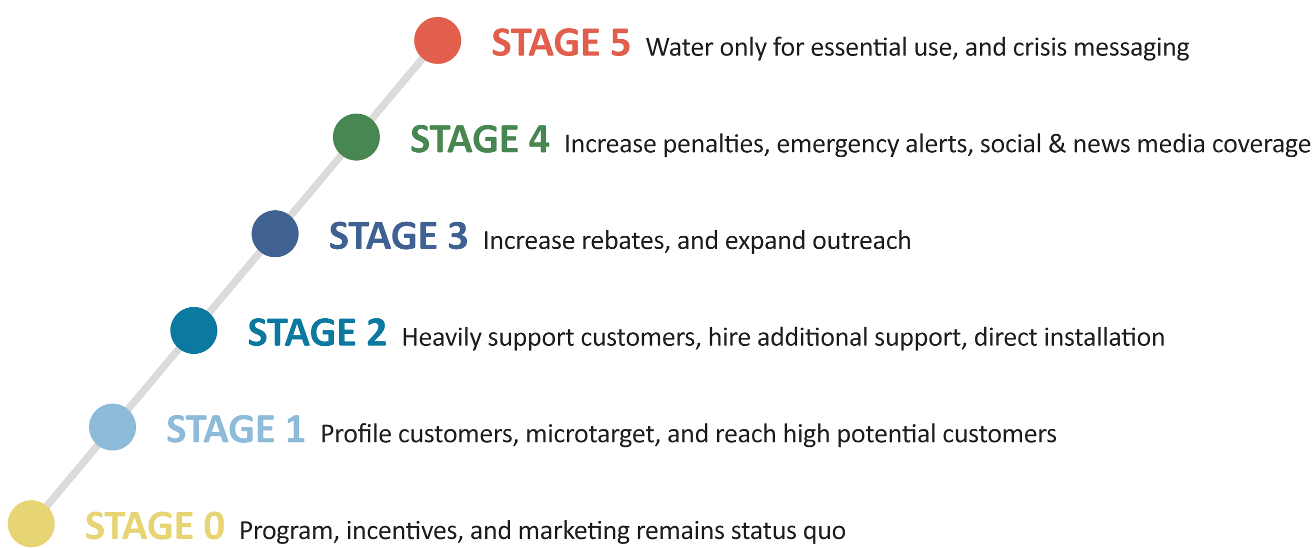

Figure 21. Blueprint for Deployment of Strategic Actions

On the following pages are snapshots of the programs, messaging, and activities for each drought stage:

STAGE 0

Goal: Customers to create drought sustainable properties prior to emergency conditions. Continue working towards goal with current strategies.

Programs:

- SoCal WaterSmart Residential and Commercial Rebates
- Turf Replacement Program
- Residential Irrigation Tune-up
- Home Surveys
- Landscape Workshops
- Design Services

Continue the success of the Residential Irrigation Tune Up Program. Work to increase response for the Turf Replacement Program through increased outreach and a higher level of linkage to support services. Implement the FreeSprinklerNozzles.com with online nozzle ordering and home delivery program. Implement the Leak Detection Pilot program.

Messaging: & Outreach: Reinforce the importance of creating/maintaining a water efficient property as preparedness for future water shortages.

Restrictions: Continue with current restrictions. Stage 0 restrictions vary agency-by-agency.

STAGE 1

Goal: Minimum 1 – 5% decrease in water use.

Programs: Programs remain the same.

Messaging & Outreach: Define ***Watch*** Condition and utilize in general customer messaging.

Begin profiling customers and micro-target high potential customers, utilizing messaging that will best resonate with those customers.

Restrictions: Consider escalation of local water waste prohibitions.

At this stage, agencies will communicate to their customers that there’s a need to increase water efficiency levels and will ask everyone to do their part to save.

STAGE 2

Goal: Minimum 6 – 15% decrease in water use.

Programs: Implement direct installation programs including the Residential Smart Irrigation Direct Installation and the School Smart Irrigation Direct Installation. Hire additional landscape designers to expand Landscape Design services. Hold more frequent Landscape Workshops. Increase the volume of Home Surveys performed.

Messaging & Outreach: Define ***Warning*** Condition to use in general customer messaging.

IEUA continues profiling and micro-targeting of high potential customers. Introduce influencer marketing (role models and respected community members).

Restrictions: Prepare WEFlex proposals and plans for expanded customer communication and enforcement administration.

STAGE 3

Goal: Minimum 16 - 25% decrease in water use.

Programs: Continue base programs and increase incentive amounts for turf replacement, high efficiency nozzles, smart controllers, laminar flow restrictor and plumbing flow control valves. Continue smart irrigation direct installation programs.

Messaging & Outreach: Define ***Emergency*** Condition and utilize as general customer messaging.

IEUA expands profiling and micro-targeting to include mid-range water users as well as high-water use customers. Ramp up influencer marketing.

Restrictions: Hire additional local staff and set up operations for expanded customer communication and enforcement administration.

STAGE 4

Goal: Minimum 25 - 50% decrease in water use.

Programs: Continue increased incentives and smart irrigation direct installation programs.

Messaging & Outreach: Define ***Critical*** Condition and use as general customer messaging

IEUA and Agencies strengthen the message of urgency and the community call to action.

Restrictions: Increase penalties, implement emergency alerts and new media coverage.

STAGE 5

Goal: Minimum 50% decrease in water use.

Programs: Only offer indoor plumbing and property leak detection programs. Suspend all landscape & irrigation programs.

Messaging & Outreach: Define ***Catastrophic*** Condition and utilize as general customer messaging.

Implement crisis messaging, announcing essential use only.

Restrictions: Conduct stringent enforcement of restrictions.

7 Operational and Administrative Framework

The general process and respective agency roles for each major plan component are documented in their respective sections. Additionally, this section provides a summarization of tasks and responsibilities as well as the process for updating the plan. The major tasks are:

- Conduct drought monitoring
- Investigate mitigation actions and capital improvement programs (long-term)
- Initiate regional response actions (short-term)
- Update the Drought Contingency Plan

7.1 Roles and Responsibilities

IEUA: IEUA acts as the administrative facilitator of all components of the plan. IEUA is responsible for developing regional demand and supply projections, calculating supply/demand ratio, communicating outcomes, convening the Drought Response Taskforce, implementing response strategies and actions as determined by the Drought Response Taskforce, conducting vulnerability assessments, evaluating and implementing IEUA controlled mitigation actions, and updating the plan.

Member Agencies: Member agencies are responsible for providing demand and supply projections, implementing agency-selected local mitigation actions, participation in the Drought Taskforce, and implementation of response actions including of local programs water waste restrictions.

7.2 Drought Response Taskforce Process

Once the drought monitoring framework indicates that the region has reached a specific stage of drought conditions, several actions will occur.

First, the Drought Response Taskforce will assemble.

The Drought Response Taskforce is the organizational group empowered to:

1) Create the Drought Response Plan blueprint.
2) During drought condition stages, assemble taskforce to finalize strategic response actions.
3) Work with their respective agency to implement response actions, according to plan.

The taskforce is comprised of representatives from each of the eight member agencies, and regional personnel from IEUA. The group works in a collaborative fashion to gain consensus on appropriate regional response actions.

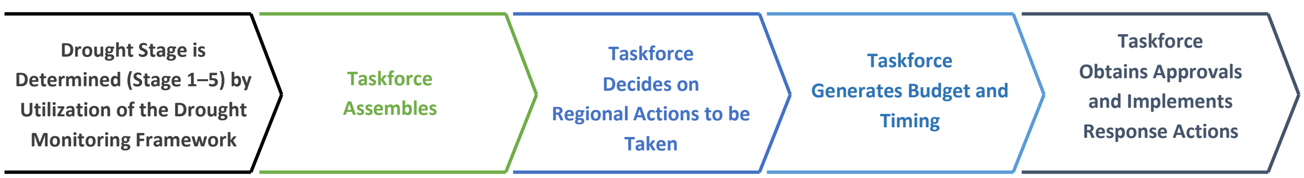
The taskforce will make decisions about the level of program and services, restrictions, and messaging to regional customers. Additionally, it's within the group's purview to determine the level of aggressiveness taken for each element of the plan.

It's important to note that, during a regional drought, an individual member agency may not be experiencing a drought condition due to their local supply mix. In this circumstance, the agency may elect in what capacity to participate in the taskforce and how to best communicate to their customers that locally there are no water supply issues, although the region is undergoing a drought stage.

Looking forwards, the taskforce will work to balance the effectiveness of regional messaging with the differing needs of individual member agencies. There are no pre-determined mandates regarding service offerings, restrictions, communications or budgets. The taskforce will collaborate on policies, while fully supporting flexibility for each agency.

The group will review the proposed actions set forth in the existing plan and make modifications as necessary. The plan was intended to be flexible and changeable. Modifications to the plan might include a change in incentive levels or program delivery mechanisms. There may also be a new water-saving technology that should be offered to customers. The taskforce might be able to secure additional grant funding, as well. Once the action plan is finalized, the taskforce will implement the programs, penalties, and communications plan, as agreed upon.

An overview of the drought response process is below:



7.3 Drought Contingency Plan Update

The Drought Contingency Plan is a working document and, as such, may be modified and updated as impactful changes occur such as another prolonged drought or increased legislative mandates. IEUA will regularly review the plan and make adjustments accordingly.

Changes and/or reviews of the plan should take place in line with the following conditions:

- Annually to assess the functionality and overall performance
- Updates to the Integrated Resource Plan
- Every 5 years to meet the Urban Water Management Plan report cycle
- As the State's Water Use Efficiency Framework policies are finalized

7.4 Operational and Administrative Summary

The table below overviews the activities, responsibilities, roles, for procedures for the operation and administration of the DCP.

Table 11. Operational and Administrative Framework

Activity	Responsibilities	Roles	Procedures
Monitoring	Collect and distribute indicator data	IEUA	Distribute identified data to member agencies via email, once a year.
	Develop annual demand projections	IEUA	Include demand projections with indicator data, annually.
	Report on projected annual supplies and demands	Member Agency Water Managers	Provide annual supply and demand projections, each year to IEUA via email.
	Review projection data and convene Taskforce (as needed)	IEUA	Determine the supply/demand ratio (regionally and for the individual member agencies) and if a regional shortage is predicted, convene the Taskforce within two weeks.
Mitigation Actions	Evaluate and prioritize mitigation projects	IEUA and Member Agencies	Continued support of regional planning efforts.
	Strategically pursue Implementation	IEUA and Member Agencies	Identify and secure funding for high-priority actions.
Response Actions	Review regional shortage conditions	Drought Response Taskforce	Once shortage is predicted, meet and review the regional conditions.
	Decide what regional actions to take	Drought Response Taskforce	Considering regional and agency-level shortage, formulate a strategy to achieve needed reductions based on consensus of the Taskforce.
	Generate budget and timing for implementation	Drought Response Taskforce	Based on consensus of the Taskforce.
	Obtain approval and implement actions	Drought Response Taskforce	Present proposed actions and budget to the IEUA Board and member agency Boards as appropriate.
Update DCP	Plan evaluation	IEUA	Annually conduct a review of the supply/demand projection reporting, identify data gaps and inefficiencies. Streamline and correct shortfalls. If response actions initiated, conduct review of results and modify plan.
	Updating the plan	IEUA and Member Agencies	Comprehensive review of DCP and updates to the framework as needed.

Appendix A: Summary of Demand Projections Method and Rationale

IEUA Drought Contingency Plan

Demand Projections

There are numerous approaches available for projecting urban water demands. Both the 2015 IEUA Regional Urban Water Management Plan (UWMP) and the 2016 Integrated Water Resources Plan (IRP) applied elaborate data intensive methodologies to develop long-term projections within the service area for planning purposes. Included in these projections are varying levels of uncertainty as the time-horizon extends ten, fifteen, twenty, and out to thirty-five years into the future. Factors that influence demands include indoor and outdoor water use practices, urban development, annual precipitation, and population growth. Due to the nature of these uncertainties, the IRP provides ranges for future demands as low-, medium-, and high-projections.

For the purposes of the drought monitoring framework however, the demand projections are needed for very near-term planning and are intended to reflect the estimated water-use from one year to the next on a monthly time-step. Water demands are often strongly correlated from one year to the next as water practices are generally slow to shift to more or less efficient practices, and development is typically a gradual process. On the other hand, annual precipitation and other water restrictions can vary significantly from one year to the next.

The proposed approach for the IEUA drought monitoring framework demand projections would rely on the rolling average for the previous five years for each member agency. This approach is consistent with the timeframe used for wastewater projections which also relies on a five-year historical average. In addition, the five-year averages for the monthly demands were compared to the three-year averages for each of the member agencies and found to be relatively similar in most cases, though there were some variations. The member agency monthly averages for the previous three- and five-year periods are attached are on pages 3-5 of this Appendix.

For the drought monitoring framework, monthly demands for the five previous years would be averaged and used for the current year's monthly projections. These demand values would be provided as reference to the water managers when they generate their four-month supply projections for the drought monitoring purposes. If there are local circumstances or external drivers that have significantly shifted the expected demands from the historical averages, the water managers could adjust the demands as they saw necessary. For reference, Table 1 provides the five-year averages for each member agency based on data from the Chino Basin Watermaster for the fiscal years 2013/2014 through 2017/2018. In addition,

Table 2 shows an example of the projected 4-month demands for the City of Chino starting at the end of July 2019.

Based on further feedback from the member agencies, this approach for generating demand projections will be incorporated into the Drought Monitoring TM, and eventually the Drought Contingency Plan.

Appendix B: Summary of Member Agency Water Shortage Stages

IEUA Drought Contingency Plan

Cucamonga Valley Water District Existing Water Shortage Stages

Stage	Water Supply Condition*	Reduction (shortage imposed)	Response Action Type
1 - Encouraging Water Use Efficiency	Normal Supply	0%	Stage 1 = Mandatory Prohibited Water Practices.
2 - Water Watch	Supplies reduced by 10%	10%	In addition to Stage 1, reduce water usage by 10%, invoke outdoor watering conditions.
3 - Water Alert	Supplies reduced by 15%	15%	In addition to Stage 2, reduce water usage by 15%, invoke additional outdoor watering conditions.
4 - Critical Water Alert	Supplies reduced by 20%	20%	In addition to Stage 3, reduce water usage by 20%.
5 - Water Emergency	Supplies reduced by 25%	25%	In addition to Stage 4, reduce water usage by 25%.
6- Severe Water Emergency	Supplies reduced by 35%	35%	In addition to Stage 5, reduce water usage by 35% due to catastrophic event or severe drought, and additional end-user prohibitions.
7 - Water Crisis - Catastrophic	Supplies reduced by 50%	50%	In addition to Stage 6, reduce water usage by 50% due to catastrophic event or severe drought, and non-essential outdoor water may be prohibited and water for construction purposes curtailed.

* Supplies may be reduced below the planned levels due to such causes as extreme (worst case) drought conditions, unplanned outages of local and imported water supply facilities due to earthquakes or other major disasters, prolonged power outages, water contamination, or any other catastrophic loss of supply.

City of Ontario Existing Water Shortage Stages

Stage*	Water Supply Condition	Reduction (shortage imposed)	Response Action Type
0	Normal Supply	5%	Voluntary reductions for water use efficiency.
1	When water conservation goals not met through voluntary reduction or supplies reduced by 10%	Up to 10%	Stage 1 prohibitions implemented to reach 10% mandatory reduction (voluntary restrictions become mandatory).
2	Supplies reduced by 10% to 20%	> 15%	Stage 2 prohibitions implemented to reach at least 15% mandatory reduction.
3	Supplies reduced by more than 20%	> 20%	Stage 3 prohibitions implemented to reach greater than 20% mandatory reduction (includes no use of potable water for construction/grading).
4	Supplies reduced by more than 50%	Up to 50%	State 4 prohibitions implemented to reach up to 50% mandatory reduction (includes significant restrictions on landscape irrigation).

* Stage 0 prohibitions are entirely voluntary. Stages 1 to 4 prohibitions will be progressively implemented according to the severity of the water crisis.

City of Chino Existing Water Shortage Stages

Stage*	Water Supply Condition	Reduction (shortage imposed)	Response Action Type
0	Adequate Water Supply Conditions	0%	Permanent measures / restrictions to ensure water use efficiency.
1	When water conservation goals not met through voluntary reduction or supplies reduced by 10%	Up to 10%	Stage 1 restrictions implemented upon city council declaration of anticipated supply reduction of 10% or less (restricted outdoor irrigation and refill of lakes/ponds).
2	Supplies reduced by 10% to 20%	10% - 20%	Stage 2 restrictions implemented upon city council declaration of anticipated supply reduction of 10% to 20% (increased outdoor irrigation restrictions).
3	Supplies reduced by more than 20%	> 20%	Stage 3 restrictions implemented upon city council declaration of anticipated supply reduction of more than 20% (no water to new land development projects).

City of Chino Hills Existing Water Shortage Stages

Stage*	Water Supply Condition	Reduction (shortage imposed)	Response Action Type
1	Normal Supply	0%	Voluntary Water Conservation Alert: all elements of Stage 2-4 restrictions on voluntary basis.
2	Moderate Water Conservation Alert	Up to 10%	Stage 2 restrictions implemented upon city council declaration of anticipated supply reduction of 10% or less and voluntary conservation does not achieve the desired reduction (restrictions on outdoor irrigation and water features).
3	High Water Conservation Alert	10% - 25%	Stage 3 restrictions implemented upon city council declaration of anticipated supply reduction of 10% to 25% (no refilling of swimming pools or construction dust control).
4	Severe Water Conservation Alert	<25%	Stage 4 restrictions implemented upon city council declaration of anticipated supply reduction of more than 25% (no outdoor water use at any time).

* Stage 1 prohibitions are entirely voluntary. Stages 2 to 4 prohibitions will be progressively implemented according to the severity of the water crisis.

City of Upland Existing Water Shortage Stages

Stage*	Water Supply Condition	Reduction (shortage imposed)	Response Action Type
0	Adequate Water Supply Conditions	0%	Permanent measures / restrictions to ensure water use efficiency.
1	Significant Shortage	n/a	Stage 1 restrictions implemented upon city council declaration of anticipated supply not enough to meet demand (restrictions on outdoor irrigation).
2	High Shortage	n/a	Stage 1 restrictions implemented upon city council declaration of anticipated supply not enough to meet demand, despite Stage 1 restrictions (restrictions for washing vehicles and surfaces outdoors).

* percentages not associated with Stages 1-2

Fontana Water Company Water Shortage Stages

Stage*	Water Supply Condition	Reduction (shortage imposed)	Response Action Type
0	Adequate Water Supply Conditions	0%	Permanent measures / restrictions to ensure water use efficiency.
1	Water Alert	n/a	Stage 1 restrictions implemented if Commission, the utility, or authorized government agency determines that measures are needed to reduce water consumption (restrictions on timing and frequency of outdoor irrigation).
2	Water Shortage	n/a	Stage 2 restrictions implemented if Commission, the utility, or authorized government agency determines that measures are needed to reduce water consumption and further reduction is needed to provide utility service (increased irrigation restrictions).
3	Water Shortage - further demand reductions	n/a	Stage 2 restrictions implemented if Commission, the utility, or authorized government agency determines that measures are needed to reduce water consumption and further reduction is needed to respond to existing available water supply conditions (no dust control or filling of ponds / lakes).
4	"Emergency" Water Shortage	n/a	Stage 3 restrictions implemented upon Commission, the utility, or authorized government agency determines that measures are needed to reduce water consumption due to a critical water shortage emergency. Stage 1-3 are not sufficient to comply with demand reductions (no outdoor water use).

* percentages not associated with Stages 1-3

Monte Vista Water District Existing Water Shortage Stages

Stage*	Water Supply Condition	Reduction (shortage imposed)	Response Action Type
1	Adequate Water Supply Conditions	0%	Permanent measures / restrictions to ensure water use efficiency.
2	Significant Water Supply Shortage	10% - 25%	Stage 2 restrictions implemented if Board of Directors finds that current or near-term water supply conditions require a 10% to 25% reduction (outdoor irrigation restrictions).
3	Critical Water Supply Shortage	25% - 40%	Stage 3 restrictions implemented if Board of Directors finds that current or near-term water supply conditions require a 25% to 40% reduction (irrigation restrictions, no vehicle washing, no refilling of pools) .
4	Emergency Water Supply Shortage	> 40%	Stage 4 restrictions implemented if Board of Directors finds that current or near-term water supply conditions require greater than 40% reduction (no new landscaping, dust control for construction, or water to maintain pools and spas).

Water Supply & Climate Change Impacts 2015—2040

Inland Empire Utilities Agency
A MUNICIPAL WATER DISTRICT

"Our climate is rapidly changing, our population is growing and more extreme weather looms on the horizon. Now is not the time to shirk from responsibility. Storage or conveyance alone will not solve all of our problems. Recycling, groundwater management and conservation, individually, won't get us there either. It will take all of the above. *We must think differently and act boldly* -- and that's exactly what California is doing."

I. Overview & Purpose

PROJECT BACKGROUND

The 2015 "Integrated Resources Plan: Water Supply & Climate Change Impacts 2015—2040" (IRP) is our region's blueprint for ensuring reliable, cost-effective, and environmentally responsible water supplies for the next 25 years. It takes into consideration availability of current and future water supplies and accounts for possible fluctuations in demand forecasts and climate change impacts. This is the first time that the region's planning has gone beyond a regional Urban Water Management Plan (UWMP) and the cities and water agencies (Agencies) have worked collaboratively to develop a comprehensive water resources plan. The sphere of influence for the 2015 IRP is the Inland Empire Utilities Agency's (IEUA) service area which is in southwestern San Bernardino County shown in Figure 1-1.

Two key goals of this IRP are to integrate and update water resource planning documents in a focused, holistic manner and to develop an implementation strategy that will improve near-term and long-term water resources management for the region. In addition, the IRP evaluates new growth, development, and water demand patterns within the service area and conducts an assessment of water needs and supply source vulnerabilities under climate change.

Although this is the first IRP that the region has developed, from 2000 to 2002 the region developed four foundational master planning documents which, together, functioned as an IRP. These historical documents illustrated how, since 2000, the region has recognized the increasingly uncertain future of imported water supply availability and the importance of local water supplies, particularly now with changing climate conditions. As part of its response, the region has focused infrastructure investments on local water supply development strategies to reduce dependence on imported supplies and increase drought resilient water sources (see Appendix 1 for a detailed description of foundational planning documents). These foundational documents are:

1. Chino Basin Water Master's Optimum Basin Management Plan (2000)
2. Chino Basin Organics Management Strategy (2001)
3. Recycled Water System Feasibility Study (2002)
4. Wastewater Facilities Master Plan (2002)

These documents were linked together in the 2002 IEUA Facilities Master Plan Programmatic Environmental Impact Report (EIR).

Water resources management strategies were further updated as part of the 2005 and 2010 UWMP. Individual programs were developed in reports such as the 2002 Salinity Management Plan, 2005 Recycled Water Implementation Plan, 2007 Recycled Water Three Year Business Plan, 2013 Recharge Master Plan Update, 2015 Recycled Water Program Strategy, 2015 Facilities Master

Plan Update, 2015 WUE Business Plan Update, and 2015 Energy Management Plan. The number and scope of regional planning documents that have been developed in the past 15 years illustrate both the commitment to local resource development and the emphasis on water resources sustainability.

An additional driver for the creation of the IRP was the need to strategically position the region for upcoming funding opportunities. By leveraging these funding opportunities for local projects, the region will be less vulnerable to the anticipated imported water rate increases of 4-5% annually through the next decade (MWD 2016 Forecast). The past success of the region to secure grant funding of over $258 million has made the expansion of the groundwater recharge, recycled water, and conservation programs possible. Over the next two years, more than a billion dollars of state and federal grants and loans will be available to support additional water supply development. The IRP will help position the region to pursue these funding opportunities by identifying regional water resources programs and ultimately project priorities.

CLIMATE CHANGE

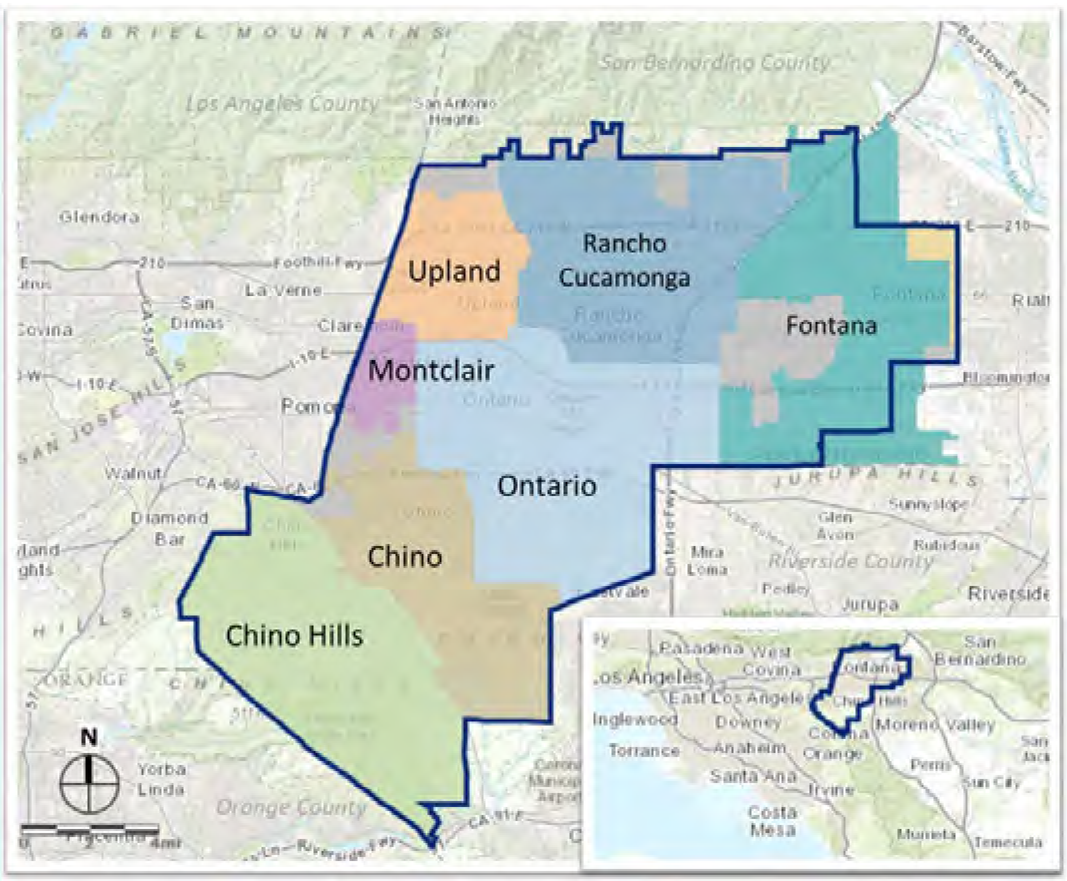
Climate change impacts have already started to create critical challenges for water resources management in Southern California. More intense storm events and the changing frequency and duration of drought years are becoming evident throughout the State and the West. This makes future water supplies available to the region more uncertain, particularly imported water resources that are uniquely vulnerable to changes in the state's snowpack.

General climate change trends projected for California are that temperatures will increase and precipitation will increasingly fall as rain rather than snow. These trends will impact water supplies in two ways: higher

The planning principal which guides the IRP is:

"... to plan for a deeply uncertain future and develop a robust strategy that can adapt and respond to a wide range of possible futures with changing conditions."

Figure 1-1: IRP Regional Planning Area Boundary



temperatures will cause increased water demands; however, infrastructure to capture rain runoff is limited as water infrastructure in California was designed to capture slow melting snowpack not rapid stormwater.

In addition, droughts are expected to occur more frequently, more intensely, and last longer. The Natural Resources Defenses Council (NRDC) estimates that if nothing is done to address the implications associated with climate change, between the years 2025 and 2100, the cost of providing water to the western United States will increase from $200 billion to $950 billion per year.

The IRP recognizes and incorporates an assessment of a range of impacts that climate change could have on water supplies for the State and region. This is done by using downscaled climate models from the Intergovernmental Panel on Climate Change (IPCC) Assessment. This IRP does not rely on historical hydrology to predict the future, but instead gathers data available from the latest climate models to project a wide range of possible future climate conditions. The information was used as a sensitivity analysis to help identify the most climate resilient water strategies and priorities for the region. This approach was selected to provide the region with a better understanding of how to effectively plan and prepare for how climate uncertainty affects our water supplies.

"Paleoclimate climate analysis has established that hydrology has the potential to vary far more widely than has been recorded in the observed record. This means that, given the scientific evidence supporting climate change, we need to look beyond historical observations to ensure that we have adequate water supplies."

"Strategies and Resources for Evaluating and Adapting to Climate Change Effects: Climate Change is Real –Now What?" Stanford Report. Fall 2014.

PHASES OF THE IRP

The development of the IRP is being done in two phases.

Phase 1 – Analysis and Recommendations: Phase 1 focuses on an extensive analysis of future projected water needs and water supply strategies under conditions of climate change and growth. Results from Phase 1 include summaries of the recommended regional water resource strategies; corresponding ranges of costs for the various supply categories; and a regionally developed, all-inclusive list of potential supply projects (local and regional). This information will be used to complete a Programmatic Environmental Impact Report (PEIR), which is needed to ensure that selected projects are grant eligible. The IRP report is the culmination of Phase 1.

Phase 2 – Implementation and Capital Improvement Program (CIP): Phase 2 will address additional detailed project level analysis including project scopes, costs, prioritization, and implementation scheduling. Phase 2 will also include the disaggregation of the regional demand and supply to the local retail level. Continued discussions will be facilitated through a Regional Water Forum. Phase 2 is anticipated to begin in Summer 2016.

IRP DEVELOPMENT

The IRP was developed from 2013-2015 by the IEUA Planning and Environmental Resources Department in conjunction with stakeholders including regional technical staff, water managers, and joint IEUA Board and Regional Policy Committee workshops.

IRP Technical Work Group: The IRP Technical Work Group consisted of IEUA member agencies, which includes the seven contracting sewerage agencies, and the retail water agencies within the IEUA service area. Meetings were held one to two times each month to discuss modeling assumptions, verify projections, establish project lists, and examine modeling results in detail. Modifications to methodology and clarifications were made with this group.

Water Managers Work Group: After technical items had been discussed and vetted, core findings and recommendations were presented at the monthly Water Managers Work Group meetings.

Joint Board and Policy Committee Workshops: The results from the IRP modeling and recommendations from the Technical and Water Managers Work Groups were presented to regional policy makers. These special joint workshops included members from IEUA's Board of Directors and the regional policy makers from the Regional Sewerage Policy Committee, as well as board members from the Monte Vista Water District (MVWD), and the General Manager from Fontana Water Company. These meetings served to update policy makers about the progress being made with the IRP as well as to receive policy direction.

Goals & Objectives: IRP Goals and Phase 1 objectives were developed by stakeholders during multiple workshops with the IRP Technical and Water Managers Work Groups, and joint IEUA Board and Regional Policy committee workshops. The overarching goals that guided the IRP process and analysis are:

- *Resilience* — Develop regional water management flexibility to adapt to climate change and economic growth and to any changes that limit, reduce, or make water supplies unavailable.
- *Water Efficiency* — Meet or exceed rules and regulations for reasonable water use.
- *Sustainability* — Provide environmental benefits, including energy efficiency, reduced greenhouse gas emissions, and water quality improvements, to meet the needs of the present without compromising the ability of future generations to meet their own needs.
- *Cost-Effectiveness* — Supply regional water in a cost effective manner and maximize outside funding.

Planning objectives for the 2015 IRP were also developed by the stakeholders. These objectives are:

- Identify key water resource supply vulnerabilities and evaluate different options that could reduce these vulnerabilities.
- Develop multiple water supply strategies to reduce future water supply imbalances.
- Evaluate strategies with different project combinations, or portfolios, to assess resiliency to climate change, including mega droughts and decadal drought impacts across future scenarios, and how the portfolios could improve regional supplies.
- Analyze portfolio results from the Water Evaluation and Planning (WEAP) model simulations to identify key tradeoffs among the portfolios.
- Develop a long-term grant application strategy for priority water resources projects.

PLANNING PROCESS

Phase 1 of the IRP was developed in three parts. The primary objective of Part I was to identity the water resource needs. Needs were developed based on an inventory of current and projected water supplies and demands. In Part 2, the IRP Technical Work Group discussed and developed regional water supply strategies that were then tested through modeling runs completed in Part 3. Individual Stages completed under each part are illustrated in Figure 1-2.

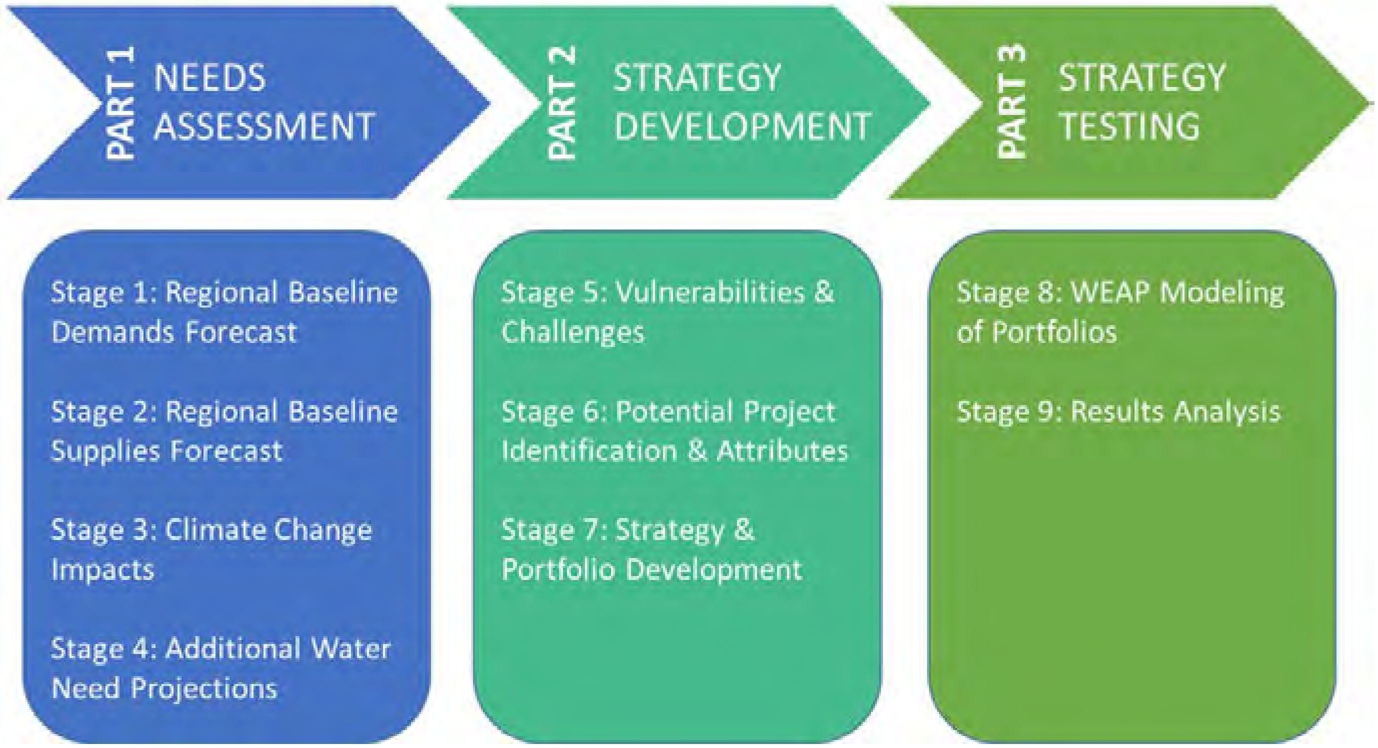
Part 1: Needs Assessment

Stage 1 - Regional Demand Forecast. Water demands for the region were projected from 2015 to 2040 using an econometric model that incorporated factors for economic conditions, growth, water efficiency, housing density, and conservation program investments approved in the FY15/16 Capital Improvement Program. Projected demands were displayed as a range to reflect trend uncertainties. The regional demand forecast is further described in Section 2 of the IRP. A complete technical description of the demand projection modeling by A&N Technical Services for this project is contained in Appendix 1.

Stage 2 - Regional Baseline Supply Forecast. Existing water resources utilized by the region were identified and analyzed to determine trends in water availability and usage through 2040. Water supplies from projects approved in the FY15/16 Ten Year Capital Improvement Program were included in this assessment. Together, these existing and new water supplies are defined as the baseline supplies through 2040.

Stage 3 - Climate Change Impacts. IEUA worked with the RAND Corporation to develop a water demand and supply model to evaluate the impact of climate change

Figure 1-2: IRP Phase 1 Planning Process Diagram



on the IEUA service area. The model, used as a baseline, tabular estimates of IEUA's supplies and demands. A set of 106 climate scenarios for the IEUA region were derived from downscaled general circulation model results used for the Intergovernmental Panel on Climate Change Assessment Reports 3 & 5. These data suggest that regional temperatures would likely increase between 0.5-3.5°F by 2040. Precipitation was highly variable and showed no clear trend across the ensemble of scenarios.

The climate scenarios and baseline water demands and supplies were then entered into a water management model developed in the Water Evaluation and Planning (WEAP) modeling system. The WEAP model used these inputs to estimate how water demands, supplies, runoff, flows, and storage would change under the 106 climate scenarios. This approach highlighted supplies that provided greater reliability and were resilient to climate change impacts. The WEAP model results are summarized in Section 3 of the IRP. A technical description of the modeling and climate assessment is presented in Appendix 3.

Stage 4 - Additional Water Need Projections. Based on the results from Stage 3, the IRP Technical Work Group evaluated the results of the climate modeling to identify the potential water supply shortfalls that the region would need to address to meet future demands. These potential shortfalls were used to develop regional water resources strategies and portfolios during Stage 7.

Part 2: Regional Strategy Development

Stage 5 - Vulnerabilities & Challenges. Key water resources vulnerabilities and challenges facing the region were identified and prioritized by the IRP Technical Work Group. Vulnerabilities and challenges for the region include:

- *Groundwater & Stormwater* — maintaining operational safe yield (OSY); preventing land subsidence; maintaining water quality; and preventing loss of natural infiltration
- *Recycled Water* — addressing increased total dissolved solids (TDS) as a result of indoor water use efficiency programs; regional interest in recycled water exceeding local supplies; competing uses of

existing supplies for direct use and for groundwater recharge; and energy intensity of additional treatment levels for direct potable.

- *Imported Water—* potential for catastrophic interruption; dependence on the MWD Rialto feeder pipeline; and constraints on supplies due to State Water Project (SWP) availability and Colorado River Basin over allocation and drought.
- *Other—* need for infrastructure redundancy; variability of surface water supplies; impact of new energy and water use efficiency standards; increasing salinity in source water; and avoiding stranded assets.

Stage 6 - Potential Project Identification and Attributes. A comprehensive list of potential water supply projects was developed based on previous and parallel planning efforts, including the Recycled Water Program Strategy, Wastewater Facilities Master Plan Update, 2013 Recharge Master Plan Update, Water Use Efficiency Business Plan (WUEBP), FY15/16 Ten Year Capital Improvement Plan (TYCIP), Santa Ana River Conservation and Conjunctive Use Program (SARCCUP), drought project list, and conceptual projects identified during the IRP process.

Individual projects were grouped into larger project categories. In some cases, categories were divided into multiple tiers which allowed the IRP Technical Work Group to either phase in similar projects over time or accelerate implementation by selected multiple tiers. Individual projects were also tagged according to their ability to address challenges and constraints facing the region.

Stage 7 - Strategy and Portfolio Development. Drawing upon information from Stages 3 and 4, the IRP Technical Work Group developed five water supply strategies to understand how combinations of projects could meet future water needs and address the challenges and constraints facing the region. A decision support tool, developed by the RAND Corporation and described in Appendix 3, supported this process. The five water supply strategies are:

- *Strategy 1:* Maximize Chino Basin groundwater, including prior stored groundwater
- *Strategy 2:* Recycled water program expansion
- *Strategy 3:* Recycled water & conservation program expansions
- *Strategy 4:* Maximize supplemental water supplies and recycled water supplies
- *Strategy 5:* Maximize imported water supplies with moderate conservation

A total of eight project portfolios were developed to test the five strategies under the WEAP model. Strategies and results are fully described in Section 4 of the IRP.

Part 3: Strategy Testing

Stage 8 - WEAP Modeling of Portfolios. Each portfolio was run through the WEAP model against the 106 climate scenarios. For comparison, a baseline portfolio that was limited to the baseline supplies identified in Stage 2, was also run through the WEAP model. WEAP model results were evaluated both in terms of the portfolio's ability to meet projected demands and whether surplus supplies were stored or used over time. Results are fully described in Section 4 of the IRP.

Stage 9 - Results Analysis. Portfolio performances were compared to the baseline portfolio results in order to determine the affect of the each portfolio on water supplies. Since there were 106 results per portfolio from the climate runs, it was beyond the scope of Phase 1 of the IRP to evaluate the nuances of the individual climate runs. Instead, the range of results that fell within 75% of the model runs were analyzed. The 75% criteria was chosen to eliminate outlier results which could have large cost implications.

Regional recommendations were developed based on: (a) the ability of a strategy to meet future demands and develop a surplus supply buffer and (b) input from the IRP Technical Work Group on the strategies that best met regional interests. Conclusions are discussed in Section 5 of the IRP. These recommendations will be used to target future grant applications. The development of future water resources projects will be done during Phase 2 of the IRP.

2. Water Demand Forecast

II. Water Demand Forecast

INTRODUCTION TO WATER DEMANDS

Section 2 outlines the process used to identify water demands for the region through 2040. These water demands include urban, environmental, and regulatory needs. Urban demands, also known as retail municipal and industrial (M&I) demands, represent the full spectrum of urban water use within the service area including commercial, institutional, industrial uses, and residential service for approximately 844,000 people. In addition to urban demands, regional water demands also include environmental discharge obligations to the Santa Ana River and contractual water commitments.

WATER DEMAND SETTING

Since the 1990s, approximately 90% of the region's water demands have come from urban M&I users with the remaining 10% coming from agricultural users (source: 2010 IEUA UWMP). Overall urban water demand since 1995 has increased by approximately 20%, despite a regional growth of 30% (approximately 200,000 more residents). This is indicative of new water use behaviors, such as efficient irrigation and more efficient indoor fixtures, which prolong the availability of current regional water supplies into the future. The 2010 UWMP estimated total urban demand by the year 2015 to be approximately 272,000 acre-feet per year (AFY). However, actual demands have grown more slowly, increasing by only 3,000 acre-feet (AF) over the past four years from approximately 197,000 AFY in FY2010/11 to 200,000 AFY in FY2014/15 as shown in Figure 2-1. This is due in part to delayed growth as a result of the economic recession, as well as changes in plumbing code, implementation of water use efficiency programs, and responses to current water supply challenges such as the drought that California has been experiencing since 2012.

The impact of plumbing code changes and the implementation of water use efficiency programs was quantified in the recent 2015 WFMP flow monitoring. IEUA monitoring of new versus older residential developments showed that urban usage patterns have decreased from a regional indoor flow average of 55 gallons per capita per day (GPCD) down to 37 GPCD in new developments. This is consistent with new development trends throughout California (Codes and Standards Research Report: California's Residential Indoor Water Use. May 2015). This indicates that future developments will require less water, reducing the overall regional need for additional water supplies. This shift has significant implications for future wastewater and recycled water planning. Regional treatment plants may not need to be expanded for hydraulic capacity as quickly as previously thought (potentially saving regional capital); however, treatment plants will have to be expanded for treatment capacity for wastewater strength (because there will be greater concentrations of solids and TDS), and future available recycled water supplies may be lower than projected.

Outdoor water use provides the largest potential for improved water efficiency and additional water savings in the region. As part of the IRP, A&N Technical Services conducted a study to estimate the amount of indoor and outdoor water use in the region. The study, which used data from the City of Ontario, found that outdoor irrigation accounts for approximately 60% of total urban demand. (Refer to Appendix 3 for the full technical memo.)

METHODOLOGY

This IRP uses an econometric model to forecast urban water demands. This water demand model incorporates various influences which impact urban water demand such as population, employment, economics, weather, and conservation activities.

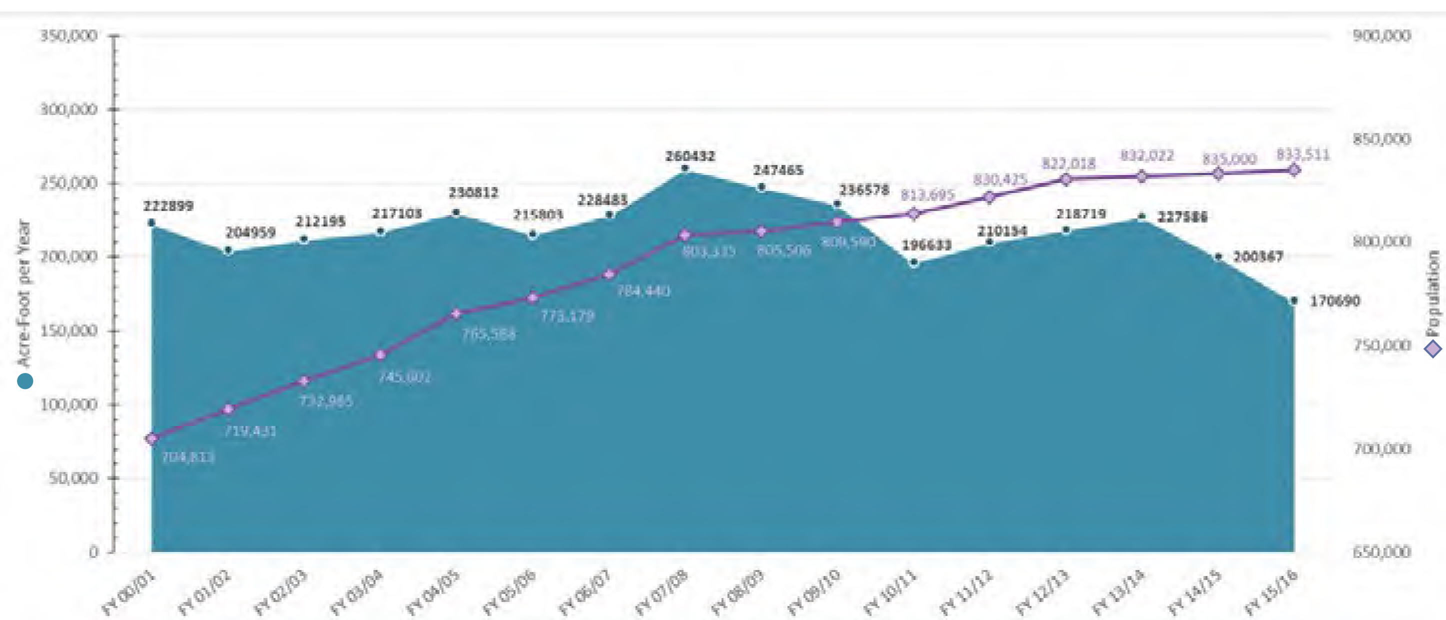
The IRP water demand model was developed by:

- Acquiring the latest regional demographic forecasts from the Southern California Association of Government "2012 Regional Transportation Plan".
- Inputting the demographic data into the econometric model equations to generate a base demand forecast.
- Calibrating the base demand forecast to identify corresponding water demand influences caused by factors including weather, employment, and economic cycles. For this IRP, a total of 12 factors were identified.
- Inputting the latest version of the Alliance for Water Efficiency (AWE) tracking tool for water savings that result from building codes and appliance standards (passive conservation) as well as regional programs that promote conservation (active conservation). Water savings are subtracted from water demand forecasts to ensure that water conservation is incorporated into the projections.
- Developing multiple water demand scenarios to plan for a range of possible futures.

URBAN M&I DEMAND PROJECTION FACTORS

To forecast urban M&I water demand through 2040, past and present urban water uses were assessed. This included an evaluation to determine which factors or influences impact demands and the corresponding

Figure 2-1: Regional Annual Water Use



Note: Annual water use includes imported water, surface water, groundwater, recycled and desalter production. FY 15/16 usage is projected based on 25% reduction from FY13/14 magnitude of their effect. A total of twelve water demand factors were identified along with their corresponding influence on water demand. Factors that influenced regional water demand were as follows:

1. Household size — single family residential (SFR), multi-family residential (MFR)
2. Land development and community density
3. Median household income
4. Customer response and water use behavior
5. Marginal water price
6. Active and passive conservation
7. Weather and climate change
8. Economic cycle
9. Short-term weather
10. Residential community mix of SFR and MFR
11. Weather and climate change
12. Conservation activities (demand management and water use efficiency)

Of the twelve factors, four were found to have a significant impact on regional urban M&I water demands and are described below. The remaining factors are described in Appendix 4. The four main factors were:

- ***Land Development and Community Density:*** regional development trends show that per capita water usage decreases with the shift towards higher density developments featuring smaller landscape areas.
- ***Weather and Climate Change:*** water use increases under hotter and drier conditions.
- ***Customer Response and Water Use Behavior:*** public increases conservation in response to statewide calls for conservation and permanent water use reductions.
- ***Economic Cycle:*** market conditions impact water usage, with recessions reducing water use and periods of growth increasing water use.

Land Development and Community Density

In the last decade, a relatively new type of housing development has emerged with higher housing densities. This is a national as well as a regional trend. These developments feature medium to large single family homes, usually built with minimal landscaping on small lots, also known as “zero-lot-line” housing. Irrigable landscaped areas in these developments are much smaller than traditional developments in the region have been. As a result, the higher density housing caused by these type of development trends lead to lower water use per housing unit because the reduced space for landscaping requires less irrigation.

For comparison purposes and to help anticipate a range of uncertain futures, Tables 2-1 and 2-2 summarize the sources of land use data and ranges of housing density incorporated into the demand forecast model. Land use data was sourced from the General Plans of the cities in the region, the Metropolitan Water District’s (MWD) 2010 water demand model (2010 MWD_MAIN), and regional growth plans such as SCAG’s 2012-2035 RTP/ Sustainable Communities Strategy (SCS) (2012 RTP/SCS).

Land use density is the variable that will have the largest impact on future demands. Comparing the demand forecast from the cities’ General Plan data to the forecast presented in the 2010 Urban Water Management Plan (UWMP), there is a difference of at least 60,000 AF in total urban M&I demand by the year 2040.

This difference is further heightened when the UWMP urban M&I demand forecast is compared to the demands tied to higher housing density values described in recent General Plan EIR amendments throughout the region. These higher densities are also consistent with SCAG’s 2012 SCS density levels. For example, when the 2010 UWMP demands are compared to the demand associated with high density presented in Tables 2-1 and 2-2, there is a difference in total urban M&I demand in the year 2040 of approximately 105,000 AF.

Weather and Climate Change

Weather has a large impact on the amount of water that customers need. Under hotter and drier conditions, water use increases at the same time that supplies may be constrained. With climate change, this trend is likely

Table 2-1: Single Family Housing Density Variability

Data Source	Low (Units per Acre)	Average (Units per Acre)	High (Units per Acre)
General Plans	1.2	2.7	4.2
2012 RTP/SCS	2.3	3.7	5.4
2010 MWD_MAIN	3.2	3.2	3.2

Table 2-2: Multi-Family Housing Density Variability

Data Source	Low (Units per Acre)	Average (Units per Acre)	High (Units per Acre)
General Plans	9.7	13.5	17.3
2012 RTP/SCS	8.4	13.5	17.0
2010 MWD_MAIN	10.9	10.9	10.9

Table 2-3: Climate and Weather Effect on Water Demands

By Year	Increase in Temp. (F)	Effect on Water Demand	Probability
2040	3.6 degrees	+4.3%	80th percentile
Multiple Dry Years		+5.98%	Varies by climate run

to be exacerbated in the near future.

In fact, climatologists have changed the way they view drought in years past and now recognize ongoing higher temperatures and longer drought conditions may be the "new normal" for California. A study conducted by scientists at Stanford University entitled "Anthropogenic Warming Has Increased Drought Risk in California" has linked climate change with "more frequent occurrences of high temperatures and low precipitation that will lead to increased severe drought conditions" (Stanford, 2015). In addition, over the past two decades, droughts have occurred more frequently than in the previous century, with 14 droughts occurring between 1896 and 1994, and six occurring between 1995 and 2014.

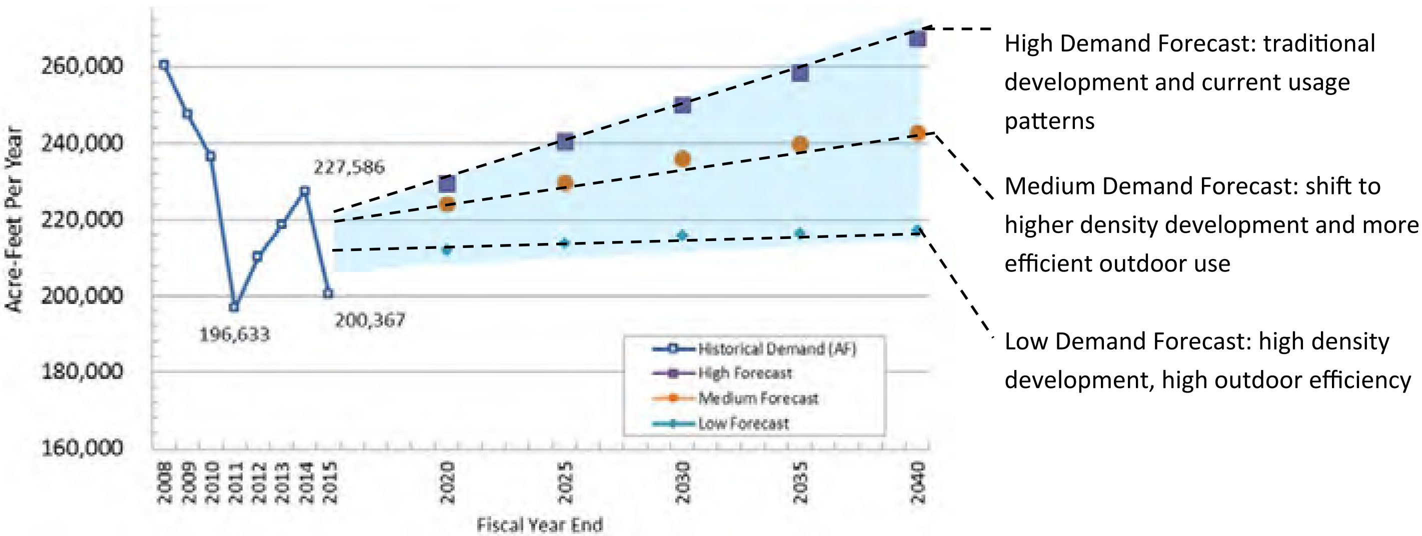
Weather-induced change in demands was accounted for in two ways. First, an adjustment was made for long term climate change based on the National Oceanic and Atmospheric Administration (NOAA) Technical Report, the National Environmental Satellite, Data, and Information Service (NESDIS) 142-5: Regional Climate Trends and Scenarios for U.S. National Climate Assessment. The report stated that increased atmospheric emissions have the potential to increase water use by as much as 4.3%.

As a result of these outlooks on future climate conditions and recent weather trends, the 2015 IRP demand forecast model includes outdoor water demand adjustments to account for climate change. IEUA performed a series of sensitivity analyses of urban outdoor demand and weather conditions. By 2040, IEUA estimates that one dry year would increase demand by 5.6%. Similarly, a one wet year would decrease outdoor demand by 5.6%. A longer period of dry weather (3-years) would increase demand by 8.9%. Separately IEUA estimates the long-term effect of warming on outdoor

Table 2-4: Urban M&I Forecast

Urban M&I Forecast	2015	2020	2040
High Forecast	225,000	230,000	267,000
Medium Demand Forecast	225,000	220,100	238,600
Low Demand Forecast	225,000	212,000	217,400

Figure 2-2: Regional Urban Water Demand Forecast



demand. It was found that for each degree temperature increase (in Celsius), outdoor demand would increase by 3%. Together these factors were applied to the climate scenarios to estimate how outdoor demand could change due to weather in the future.

Table 2-3 summarizes the climate and weather factors applied to urban outdoor demand used during WEAP modeling outlined in Section 4.

Customer Response and Water Use Behavior

Since 2012, Southern California has been challenged by drought conditions. This led to calls for voluntary and mandatory water use reductions from Governor Brown, numerous news articles about water supply conditions, and massive public outreach campaigns from water agencies across the State. Increased public awareness of water supply conditions resulted in measurable water savings across the State.

Regionally, these behavioral changes reduced urban M&I demands by 4.6% in FY14/15. Lifestyle changes in combination with the anticipated permanent state water restrictions are expected to keep demands suppressed.

For the purpose of the IRP demand forecast model, it is assumed that changes in water use behavior will continue into the future and will maintain a reduced demand by 4.6% through the year 2040.

Economic Cycle

The economy is also susceptible to change and it is likely to continue to change between strong and weak market conditions. During weak market conditions, urban M&I demands decrease by 7%; conversely, during strong market conditions, demands increase by 7%.

Although this is a significant impact, for the purpose of the 2015 IRP M&I demand forecast model it is assumed that the market conditions remain normal and so no adjustment was incorporated.

URBAN M&I DEMAND FORECAST

The IRP developed a range of demand possibilities to accommodate for future uncertainty caused by the various demand factors. To determine a range of urban demand possibilities, three water demand forecasts were created:

- *High Demand Forecast* – utilized housing densities from each city's General Plan and assumed that new development would use water consistent with current usage patterns—no change for outdoor, 55 GPCD indoor.
- *Medium Demand Forecast* — utilized 2012 SCAG RTP average housing density for occupied housing units and applied indoor and outdoor landscape efficiency standards established by Assembly Bill 1881 (also known as the Model Water Efficient Landscape Ordinance) for existing and future development. For the medium demand forecast, existing outdoor use is limited to 70% of evapotranspiration (ETo). Future outdoor use is limited to 60% ETo, and indoor water use is reduced from 55 GPCD in 2015 to 35 GPCD by 2040 for new development.
- *Low Demand Forecast* – utilized 2012 SCAG RTP high housing density and applied indoor and outdoor landscape efficiency standards established by AB 1881. For the low demand forecast, existing outdoor use is limited to 70% of ETo. Future outdoor use is limited to 60% ETo, and indoor water use is reduced from 55 GPCD in 2015 to 35 GPCD by 2040 for new development.

The range of urban water demand possibilities for the region through 2040 are shown in Table 2-4. When compared to historical demands, the region has experienced over 25,000 acre-feet (AF), or 12% reduction since FY2013/14 as shown in Figure 2-2. This is due in part to delayed growth as a result of the economic recession, but primarily from customer response from continued drought conditions and the State mandated water use restrictions. If demand continues to trend at FY2014/15 levels, the 2015 IRP demand model (which was created in 2014) will need to be updated to account for this regional shift in water use behavior. Additional technical data is provided in Appendix 1 which includes technical memorandums that detail the process used to develop the econometric water demand model.

To prepare the region for future uncertainty and to ensure sufficient water resources and adequate infrastructure capacity, the high urban water demand forecast was selected by the IRP Technical Work Group. This planning assumption was recognized to be a conservative forecast as recent residential developments within the region are currently more efficient (given that they use less water for indoors and outdoor landscaped areas) than presumed in the model.

The benefits of using this conservative forecast for the baseline demand are that it:

- Provides a sizeable water supply buffer which protects the region from future uncertainties.
- Allows conservation to be counted as a future water supply in the demand model.

Table 2-5: Additional Continuing Operational Water Needs Forecast

Additional Water Needs Forecast	2015	2020	2040
SAR Discharge Joint Obligation (Chino Basin share)	17,000	17,000	17,000
Management Zone 1 Supplemental Recharge	6,500	6,500	0
Chino Desalter Replenishment	1,145	2,290	11,035
Total Additional Demand	**24,645**	**25,790**	**28,035**

Figure 2-3: Total Regional Demand Forecast

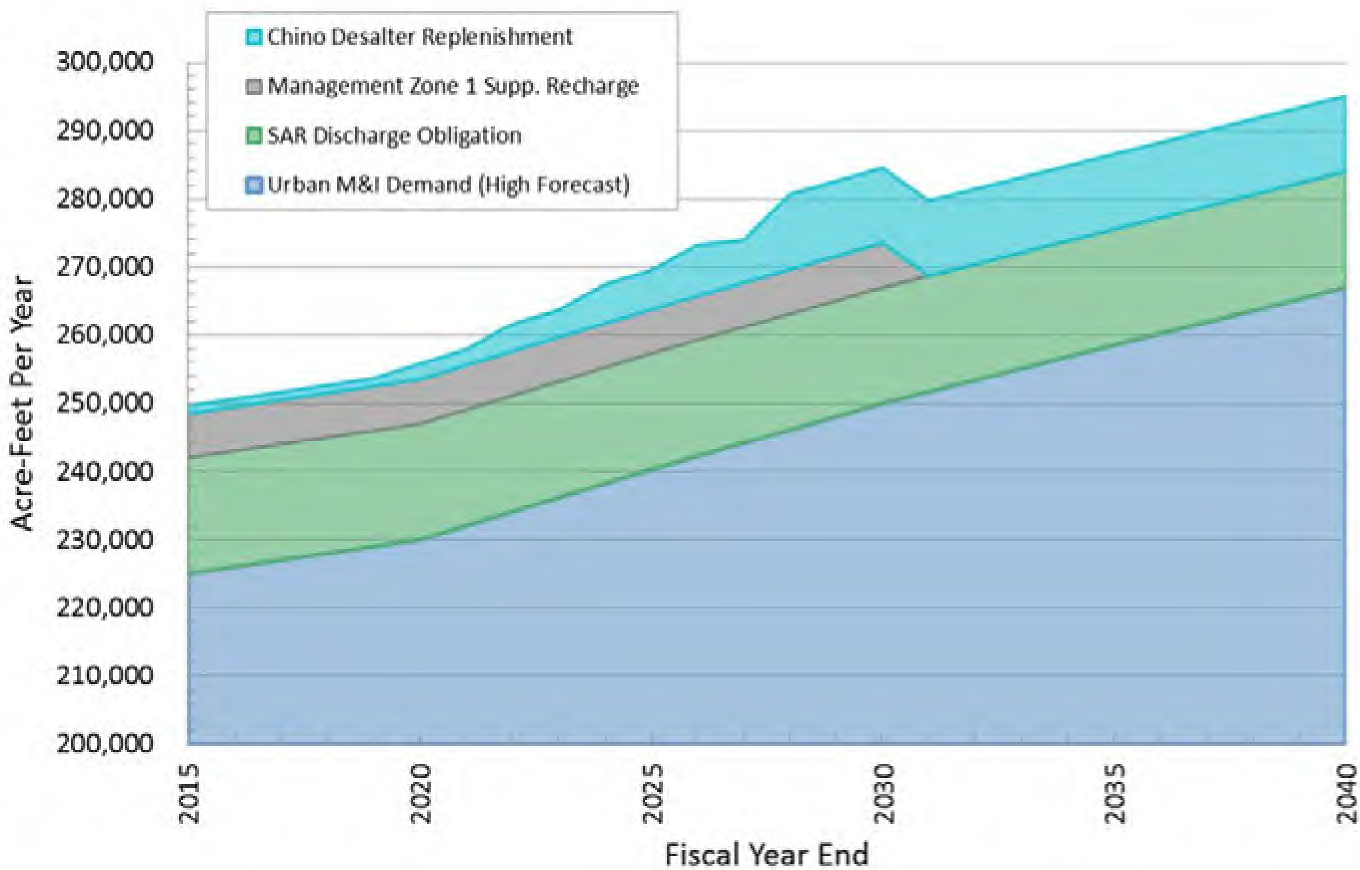


Table 2-6: Total Regional Demand Forecast

Total Regional Demand Forecast	2015	2020	2040
Urban M&I Demand (High Forecast)	225,000	230,000	267,000
Additional Continuing Operational Water Needs	24,645	25,790	28,035
Total Regional Demand	**249,645**	**255,790**	**295,035**

ADDITIONAL CONTINUING OPERATIONAL WATER NEEDS FORECAST

Current and future water demands include regional environmental and/or contractual stream flow obligations. These continuing operational water needs are not subject to the same variables as the urban M&I demands and instead are tied to standing contractual agreements and legal requirements. The water demand and supply models incorporate the following assumptions into the IRP forecasts:

- **Santa Ana River (SAR) Discharge Obligation** Santa Ana River (SAR) Discharge Obligation is a regional obligation that requires annual water discharges to the Santa Ana River above Prado dam. For the purposes of the IRP, 17,000 AFY is used as the Agency's requirement to fulfill the obligation through 2040. This is half of the 34,000 AFY minimum obligation shared with Western Municipal Water District. The region currently meets this obligation by discharging treated wastewater to the Cucamonga and Chino Creeks.

- **Management Zone 1 Supplemental Recharge** pursuant to the Peace II Agreement, Section 8.4. For the purposes of the IRP 6,500 acre-foot per year will be used to fulfill the supplemental groundwater recharge obligation within Management Zone 1. The obligation is met by Chino Basin Watermaster through recycled water recharge and/or imported water recharge.
- **Chino Desalter Replenishment** pursuant to the Peace II Agreement, Section 6.2. For the purposes of the IRP, Exhibit C dated August 16, 2015 of the safe yield reset implementation plan will be used for the groundwater replenishment obligation.

TOTAL REGIONAL DEMAND FORECAST

Regional water demands for the 2015 IRP Phase 1 are the sum of the high urban M&I demand forecast and the total additional continuing operational water needs forecast. Total water needs for the 2015 IRP are shown in Table 2-6. By 2040 it is projected that 45,400 AFY of additional supply will be needed to accommodate regional growth and other environmental and/or legally obligated stream flows.

Resources Inventory

WATER RESOURCE SETTING

The region relies on imported and recycled water supplies provided by IEUA in addition to groundwater from both the Chino and non-Chino basins and local surface water from various creeks flowing through the service area which originate in the San Gabriel Mountains. As a response to the series of droughts that have impacted Southern California over the past 100 years, including the current drought that has lasted since 2012, the region has developed a sophisticated network of water supply facilities.

Climate change is one of the key factors that will have a substantial impact on water supplies. While recent droughts in California have been significant, climate change trends indicate a future of unprecedented “megadroughts” that have the potential to last multiple decades (Science Advances, 2015). To analyze the impact of potential climate change, RAND Corporation (a nonprofit research organization) evaluated IEUA’s supply and demand balance under 106 climate scenarios that were selected from the IPCC Assessment Reports 3 & 5. Climate simulations were downscaled for the region and indicated that temperatures in the region would increase between 0.5-3.5°F. Indications for changes in precipitation varied greatly and had no clear trend.

Baseline water resource supplies were stress-tested across the 106 climate simulations to determine supply availability from 2015 to 2040 in order to establish annual expected resources. The simulations included water demand and supply inputs and calculated how demands, supplies, runoff, flows, and storage would function under each climate scenario. The individual sections of this section provide the results which illustrate the impact of climate change on future water supply. For a complete technical description of the climate simulation work by RAND, see Appendix 2.

This Resources Inventory section provides an overview of the water supplies that the region relies upon:

- Chino Basin Groundwater
- Stormwater
- Recycled Water
- Chino Basin Desalter
- Local Surface Water
- Non-Chino Basin Groundwater
- Imported Water
- Water Use Efficiency

Each supply section includes an overview of current supply use, management, and prioritization; baseline assumptions through 2040; supply challenges that may impact the future availability; additional potential water resource projects by supply type; and water management implications for the region.

POTENTIAL WATER RESOURCE PROJECTS

Future water resource projects were identified through the IRP Technical Work Group discussions. These projects are listed by category of supply. Many of these proposed projects were culled from existing planning documents, such as the Recharge Master Plan Update (RMPU) and the Recycled Water Program Strategy. The list includes conceptual projects as well as those that have been under development but have not yet been included in adopted regional Ten Year Capitol Improvement Plans (TYCIP). For the full project list compiled by the IRP Technical Work Group, see Appendix 2.

The proposed projects include capacity building and reliability investments, as well new sources of supply. Due to technical constraints, the Phase I RAND climate simulations focused on the water supply benefits of these projects and to what extent they meet water demands. This information was used to identify opportunities and build portfolio scenarios where new supplies were added to the baseline annual supplies to assess water supply resilience in 2040. These scenarios are described in Section 4.

California Buckwheat growing near San Antonio Dam

CHINO BASIN GROUNDWATER

Resource Overview

The Chino Basin is one of the largest groundwater basins in Southern California containing approximately 5,000,000 AF of water with an unused storage capacity of approximately 1,000,000 AF (source: CBWM website). Groundwater from the Chino Basin accounts for approximately 40% of regional water supplies.

San Bernardino County Superior Court created the Chino Basin Watermaster (CBWM) in 1978 as a solution to lawsuits over water rights. CBWM is responsible for management of the Chino Basin in accordance with the 1989 Judgement, 2000 Peace Agreement, 2007 Peace II Agreement, and the Chino Basin Optimum Basin Management Program (OBMP).

Water rights in the Chino Basin are held by representatives to three stakeholder groups, called Pools. The three Pools are:

- **Overlying Agricultural Pool**: representing dairymen, farmers, and the State of California
- **Overlying Non-Agricultural Pool**: representing area industries
- **Appropriative Pool**: representing local cities, public water districts, and private water companies

Although groundwater is an important local supply, the water quality in the lower Chino Basin area has been impacted by historical agricultural uses and now has high levels of nitrate and total dissolved solids (TDS). There are also some areas that exceed standards for perchlorate and volatile organic chemicals (VOCs). This lower quality water requires additional treatment, and/or blending with higher quality imported water. The Chino Basin Watermaster works in partnership with municipalities, IEUA, and the Santa Ana Regional Water Quality Control Board to address these water quality problems, including construction and operation of the Chino Basin Desalters.

The Chino Basin is subdivided into five groundwater zones, referred to as management zones. Each management zone has unique groundwater management issues. Management zones 1, 2, and 3 comprise the Chino North Management Zone. Management Zones 4 and 5 are outside of the IEUA service area. Throughout these management zones, there are 19 active spreading basins that are operated to capture stormwater, recycled water, and/or imported water for recharge into the Chino Basin.

Baseline Supply

The court judgment allocates groundwater rights by establishing an annual pumping "safe yield" for each Pool. The Operating Safe Yield (OSY) is the annual amount of groundwater that can be pumped from the basin by the Pool parties free of replenishment obligations. For planning purposes, controlled overdraft for the Appropriative Pool was not included in the IRP. Annual groundwater production in excess of the OSY is allowed by the adjudication, provided that the pumped water is replaced and recharged back into the groundwater basin.

The baseline amount for groundwater production between 2015 and 2020 is assumed to be 90,550 AFY, based on historical production of the appropriative pool parties within the IEUA service area. This amount of groundwater pumping includes recharge from natural rainfall, stormwater capture, and recharge. It does not include recharge from recycled water.

Baseline groundwater production between 2020 and 2040 is assumed to be 91,300 AFY, which is the Agencies' share of the forecasted OSY for this period and increased stormwater (SW) recharge from the Chino Basin Facilities Improvement Project. The Baseline does not include stormwater recharge from the proposed 2013 RMPU projects or recharged recycled water.

Climate

Chino Basin groundwater is dependent on rainfall and supplemental sources for recharge. Groundwater supply is impacted by climate change given that warmer temperatures and droughts increase the dryness of soil which results in less absorption when precipitation occurs and with predicted more intense periods of rainfall, water runoff will increase instead of percolating into the soil. Simulations by Wildermuth Environment Inc. showed that natural groundwater recharge (GWR) would decrease by 0.44% for each 1% decline in long-term precipitation. Groundwater supply is also impacted by development patterns (increased hardscaping) and

Table 3-1: Chino Basin Groundwater Supplies & Projects

Baseline Chino Groundwater			
Project Name	**Description**		**AF**
Baseline Chino Basin Groundwater -2015 – 2020	Baseline groundwater production through 2020 is assumed to be 90,550 AFY, based on historical groundwater production by the Agencies from 2009-2014. Includes replenishment from natural rainfall, SW capture, and recharge.		90,550
Baseline Chino Basin Groundwater	Baseline groundwater production from 2020 through 2040 is assumed to be 91,300 AFY: Includes Agencies' share of OSY (71.9%) of 127,000 AFY. Does not include SW from the 2013 CBWM RMPU or recycled water recharge as these are accounted for separately and in addition to the baseline Chino groundwater.		91,300

Chino Basin Groundwater Projects			
Project Name	**Description**	**ID**	**AF**
Groundwater Treatment (Rehab)-Increment 1, 2	This project category will rehabilitate existing groundwater production wells decommissioned due to water quality concerns. It is assumed that additional pumping would be limited by the volume of recharge occurring (over OSY). Increased well operation could supplement annual demands or help offset losses in another water supply. Increment 1 will provide up to 5,000 AFY of production. Increment 1 & 2 will provide up to 10,000 AF.	1	5,000
		2	5,000
Groundwater Treatment (new)-Increment 1, 2	This project category will construct a new groundwater production well and treatment facility to address water quality concerns. It is assumed that additional pumping would be limited by the volume of recharge occurring (over OSY). Increased well operation could supplement annual demands or help offset losses in another water supply. Each increment will provide 5,000 AF. If all increments are selected, there is a potential of up to 10,000 AFY of production.	3	5,000
		4	5,000
Production Wells-Increment 1, 2, 3, 4	With increasing groundwater recharge to the Chino Basin, new production wells may need to be constructed to recover the additional groundwater. It is assumed that additional pumping would be limited by the volume of recharge occurring (over OSY). Well operation could supplement annual demands or intermittent to help offset losses in another water supply. Each increment will provide 5,000 AF. If all increments are selected, there is a potential of up to 20,000 AFY of production.	5	5,000
		6	5,000
		7	5,000
		8	5,000
Desalter Recovery Improvement	The existing Chino Basin I Desalter (CD-1) recovers approximately 75 percent of water. Improvements could be done to increase recovery to approximately 90 percent. This water would be conveyed through the existing potable water system.	18	1,500
Six Basin Water Transfer	This project would explore the idea of developing a water transfer agreement with Six Basins. One concept is to purchase imported water for recharge into Six Basins and get in return equal volume of groundwater underflow plus agreed amount of stormwater. For example, 10,000 AF of imported water could be purchased in exchange for 10,000 AF of groundwater plus 7,000 AF of stormwater. Assume benefit 1 in 5 years.	38	17,000
Cucamonga Basin Improvements	This project category will identify projects that would result in additional groundwater production benefits coming into the IEUA service area from the Cucamonga Basin. Includes recharge facilities, treatment and production facilities to maximize supply coming into the Chino Basin.	62	2,500
Prior Stored Chino Groundwater	This category will allow supply to be taken from groundwater stored in the Chino Basin, pre 2014. It is estimated that approximately 400,000 AF of stored groundwater is available, of which 280,000 AF is made available for Agencies. This supply category will be managed on a case by case basis as selected into the Regional supply portfolios. The supply will be limited, but can be used annually or intermittent as needed.	87	8,400
Watershed Wide Water Transfers	This category of projects will construct or arrange other water transfers external to the Chino Basin. For example, dry weather flow exchange of recycled water to Orange County Water District for an equivalent amount of purchased imported water. For the purposes of the IRP, it is assumed that this category of projects will not increase supply, but increases reliability and/or quality. To occur annually or intermittent. Resiliency and flexibility benefit only.	98	5,000
Chino Basin Water Transfers	This category of projects will construct or arrange other water transfers within the Chino Basin. Projects to also include inter-agency interties for increased reliability. For the purposes of the IRP, it is assumed that this category of projects will not increase supply, but increases reliability. To occur annually or intermittent.	99	5,000
Reliability Production Wells	This project category will construct new production wells needed to replace lost production or under-performing facilities. These projects will maintain current annual groundwater production deliveries and are intended to increase operational flexibility and reliability. Increment 1 varies in capacity and will be determined on a case by case basis as selected into each of the regional supply portfolios.	100	5,000

more efficient irrigation practices.

A key conclusion drawn from the simulations is that it is important to secure supplemental water when available to recharge the Chino Basin (through direct or in lieu practices) to enable sustained or allow increased groundwater production during droughts and emergencies.

Supply Challenges
Supply challenges facing the Chino Groundwater Basin include the need to address:

- Sustainability or increased OSY for the Chino Basin.
- Loss of natural infiltration caused by higher density development, reduced outdoor landscaping, and irrigation efficiency measures.
- Targeting of groundwater recharge or limiting localized groundwater production in specific areas to help mitigate and/or prevent land subsidence.
- Recognition that different management practices may be required for groundwater recharge in each of the five management zones.
- Identification of additional supply sources for groundwater recharge to help meet Chino Basin recharge goals.
- Slowly rising levels total dissolved solids and nitrate levels in groundwater basin and corresponding potential future loss of available supply caused by this long term trend.
- Consideration of possible additional treatment infrastructure for groundwater.
- Containment of existing groundwater contamination plumes.

Supply Opportunities
The IRP process identified the potential projects listed in Table 3-1. Potential projects range from conceptual to well-developed proposals. Each project has the ability to increase the amount of supply available for groundwater recharge and/or increased groundwater production.

Implications
Groundwater stored in the Chino basin increases regional water supply reliability and resilience with minimal impacts from climate. It is important that the region account for diminished natural recharge resulting from climate and/or development impacts and take action to minimize these losses and to secure replacement sources. Otherwise future groundwater production will exceed sustainable levels. In addition, water quality is a key future constraint on groundwater production. The region will need to evaluate water quality improvement actions including the identification of potential blending water sources for recharge to attain long term salinity management and reliability goals.

Key implications for the Chino Basin groundwater supplies:

- Are not impacted by climate once water is stored in the groundwater basin.
- Are slightly impacted by receiving reduced natural recharge within the basin resulting from climate and/or development impacts.
- Can be sustained or increased through use of supplemental water for groundwater recharge (through in lieu or direct recharge) when these resources are available.
- Are a vital local emergency resource to help mitigate abnormal or catastrophic events through additional groundwater production.
- Are a climate flexible supply that can be tapped to offset either short- or long-term water supply needs.
- Provide a means for sustainable regional water management by enabling exchanges and transfers among agencies within the watershed.
- Are generated locally and are the region’s least energy intensive water supply and have minimal greenhouse gas emissions relative to imported water.
- Are cost effective relative to imported water supplies.
- Are critical to improving the region’s water self-reliance and reducing dependence on climate variable supplies such as imported water.

STORMWATER

Resource Overview

Stormwater is water that originates during rainfall and snow melt. In the region, stormwater comes primarily from surface water runoff from rain and snow starting in the San Gabriel Mountains and moving down through the Santa Ana watershed. In undeveloped areas, the soil absorbs some of the runoff and helps replenish the groundwater basin. However, developed areas with a significant amount of hardscape tend to concentrate and accumulate stormwater runoff in large quantities in a relatively short amount of time. Stormwater also runs off roofs, through streets, and into stormdrains, where these flows are largely diverted into the region's flood control channels.

The Chino Basin has 6 main flood control channels spread throughout the region. These channels collect and manage the stormwater generated within the watershed. Major flood control channels that convey stormwater within IEUA's service area include:

- San Sevaine Creek
- Day Creek
- Deer Creek
- Cucamonga and West Cucamonga Creek
- San Antonio Creek

Located on and adjacent to the channels are detention basins that are operated under a multiple-use agreement for both flood control and groundwater recharge operations. IEUA, Chino Basin Watermaster, and other agencies work closely with the San Bernardino Flood Control District to maximize the amount of stormwater that can be captured and recharged into the Chino groundwater basin. These channels also carry dry weather runoff from excessive outdoor irrigation.

Runoff that is not captured by these detention basins ultimately flows to the Santa Ana River. While there are efforts by agencies further downstream to capture these storm flows, large amounts of water can discharge to the ocean during large storm events.

Baseline Supply

The baseline amount of water that is available for stormwater recharge from existing projects is already included in the groundwater supply, described under the Chino Basin Groundwater resource sub-section. To ensure there is no double-counting in the IRP simulations, this part of the supply is not counted in the stormwater baseline.

The stormwater supply projection through 2040 includes additional water captured as the result of the construction of projects listed in the 2013. As a result, the baseline stormwater supply assumed to be available between 2020 and 2040 is 6,400 AFY as in the 2013 RMPU.

Climate

Stormwater supplies may also be impacted by temperature. Warmer temperatures cause soils to dry out through evaporation. This can lead to two competing effects. Because it is more difficult for water to penetrate dry soil, water runoff could increase. However, once the water is in the soil column, the ground retains this moisture until the soil is saturated which helps to replenish groundwater supplies. This outcome is also consistent with other larger basin studies performed by the Bureau of Reclamation and the Colorado River District. During dry conditions, IEUA has documented reductions in the expected amount of runoff from rain events into the groundwater recharge basins.

In absence of more detailed information on how future stormwater would vary with respect to precipitation, a regression formula was applied to develop baseline supplies as well as any additional supply that was selected as part of a water management strategy (see Section 4). Based on the results of the climate simulations, the 6,410 AFY baseline stormwater supply could vary from 2015 and 2020 between 900 AFY to 7,400 AFY.

Supply Challenges

Supply challenges facing stormwater supplies include the need to address:

- Dependence of these supplies on annual rainfall and snow melt.

Table 3-2: Stormwater Supplies & Projects

Stormwater Baseline		
Project Name	**Description**	**AF**
Baseline Stormwater 2015-2020	0 AF through 2020: Estimated completion of 2013 RMPU is 2020, therefore no new stormwater supply will be available until after 2020.	0
Baseline Stormwater 2021-2040	6,410 AFY for 2020 thru 2040: New stormwater supply generated from additional stormwater recharge from the recommended projects included in the 2013 CBWM RMPU.	6,400

Stormwater Projects			
Project Name	**Description**	**ID**	**AF**
Day Creek SW Capture	Modify existing basins along Day Creek to increase stormwater capture beyond the 2013 RMPU. Increase facilities to better accommodate the "big gulp" concept of approximately 2,500 AF. Assume benefit 1 in 5 years.	54	2,500
San Sevaine Creek SW Capture	Modify existing basins along San Sevaine Creek to increase stormwater capture beyond the 2013 RMPU. Increase facilities to better accommodate the "big gulp" concept of approximately 2,500 AF. Assume benefit 1 in 5 years.	55	2500
Regional LID-Increments 1, 2	Construct or modify urban development to better manage and infiltrate rainfall at the source. Projects could include bioswales and or pervious concrete installation in parking lots, street drainages. Each increment could provide up to 5,000 AFY of recharge for a total of up to 10,000 AFY recharge.	58 59	5000 5000

- Supply variability such as storm frequency, intensity, seasonality of rainfall events which are exacerbated by climate change.
- Reductions in natural infiltration into the groundwater basin caused by channelization, new development, hardscape, increased outdoor water efficiency, and open space conversion.
- Construction of additional stormwater recharge facilities in a highly urbanized area where available land may not be available or not available in the right places to capture and recharge significant volumes of water.
- Compliance with Municipal Separate Storm Sewer System (MS4) Permit low impact development (LID) stormwater retention/recharge requirements for new and existing development and quantification of corresponding water supply benefits.

Supply Opportunities

The IRP process utilized the list of potential stormwater projects shown in Table 3-2. Potential projects range from conceptual to well-developed proposals. Each project has the ability to increase the amount of supply available from stormwater by improving diversions to existing basins, constructing new basins and pumping facilities, and through on-site MS4 low impact development improvements.

Implications

Stormwater is an extremely valuable resource to the region because it is considered a "free" once the necessary facilities to capture and use this water have been constructed and maintained. It is also a high quality water source that can improves the quality of the groundwater supplies once it has infiltrated and become blended within the aquifer. Stormwater has and will likely continue to be an important element of the region's water resources as it can be stored and subsequently used. To capture large storm events additional infrastructure should be constructed. In addition, to help offset lost infiltration from increased urbanization and more efficient outdoor landscaping, increasing regional investment in MS4-compliant low impact development projects will be necessary.

Key implications for stormwater supplies:

- Are generated locally, are the least energy intensive water supply and have minimal greenhouse gas emissions relative to imported water.
- Are cost effective relative to imported water supplies.
- Are highly dependent on weather and impacted by climate.
- Will be significantly reduced during droughts when below average precipitation and drier conditions

exist.

- Require well-designed facilities that can operate under a wide range of flows.
- Are a high quality water supply and provide a supplemental source of water to blend with and improve groundwater quality.

RECYCLED WATER

Resource Overview

IEUA owns and operates four water reclamation plants: Regional Plant No. 1 (RP-1), Regional Plant No. 2 (RP-2), Regional Plant No. 4 (RP-4), Regional Plant No. 5 (RP-5), and the Carbon Canyon Water Reclamation Facility (CCWRF). These facilities provide tertiary-treated wastewater, also known as recycled water. Recycled water supplies can be used for direct non-potable uses, groundwater recharge for the Chino Basin, and for other regional discharge obligations.

Recharge of recycled water is allowed by the Regional Water Quality Control Board (RWQCB) through the OBMP, and currently provides approximately 17% of the region's urban water supply. The region secured a number of permits allowing for the direct use and groundwater recharge of recycled water. These permits define requirements for the use of recycled water (both direct use and recharge), including, but not limited to, uses, water quality limits, and monitoring requirements.

The recycled water program makes up approximately 15% of the regional water portfolio and is operated based on the following order of priorities for recycled water supply:

- Regional discharge obligations (Santa Ana River Judgement, environmental, etc.)
- Agency direct use demands
- Regional groundwater recharge

Although recycled water is an important component of the groundwater recharge program, not all of the recharge basins are able to use recycled water. Currently, 10 of the region's 16 groundwater recharge basins are permitted to receive recycled water.

During FY2014-15, the 4 regional water reclamation plants produced approximately 62,000 AF of recycled water. Based on recent wastewater projections that were calculated as part of the Wastewater Facilities Master Plan (WFMP), treated flows are expected to increase to over 85,000 AFY by 2040 as shown in Table 3-4. It is important to note that these flow estimates were based on current existing indoor water usage levels in order to ensure that facilities and pipelines are adequately sized, and are consistent with the IRP's upper demand forecast (see Section 2). However, indoor water use efficiency is increasing and new plumbing code and appliance standards are being implemented. As a result, available wastewater flows by 2040 are expected to be lower than 80,000 AFY. These water flow trends are being carefully tracked by IEUA.

Baseline Supply

As part of the 2015 Recycled Water Program Strategy (RWPS), regional direct use demand forecasts were developed. Direct use for recycled water is defined in the RWPS as the amount of water needed for landscaping, agricultural, and industrial processes. The forecasts indicate that by 2025 direct use demands will increase by 5,000 AFY. The projects required to achieve the direct use demand forecast by 2025 are included in IEUA's FY2015-16 Ten Year Capital Improvement Plan (TYCIP).

The TYCIP includes recycled water projects that will allow the region to increase both direct use and groundwater recharge deliveries. These projects will provide 30,640 AFY of direct use (including approximately 1,700 AF agriculture use) and 18,700 AFY of groundwater recharge supply by 2025. Because the TYCIP includes recycled water projects with prior commitments from the region, the corresponding amount of recycled water supply from those projects is considered baseline recycled water supply for the IRP.

In summary, the baseline recycled water supply for direct use demands is assumed to be:

- Near Term (2015 to 2020) = 25,000 AFY by 2020
- Mid Term (2020 to 2030) = 28,960 AFY by 2025
- Long Term (2030 to 2040) = 28,960 AFY by 2025

Recycled water deliveries for groundwater recharge were also updated as part of the 2015 RWPS. Similar to

Table 3-3: Wastewater Projection

	2015	2020	2030	2040
Regional Recycled Water Supply	63,900 AF	66,300 AF	77,500 AF	85,500 AF

direct use deliveries, projects required to contribute 18,700 AFY to the groundwater recharge program by 2025 are included in the TYCIP.

Therefore, baseline recycled water supply for groundwater recharge is assumed to be:

- Near Term (2015 to 2020) = 16,900 AFY by 2020
- Mid Term (2020 to 2030) = 18,700 AFY by 2025
- Long Term (2030 to 2040) = 18,700 AFY by 2025

Table 3-4 summarizes the baseline assumptions compared to the total available recycled water supply produced by the four water reclamation plants. Beyond 2025, there is a significant amount of recycled water supply that can be delivered for beneficial reuse. Additional projects will need to be constructed to increase the baseline amount of recycled water beneficially used to help meet the urban water demand for the region. Additional projects for increasing recycled water reuse are outlined below.

Climate

Under the climate simulations, wastewater flows were not impacted by climate. As a result, recycled water is the most climate resilient water supply available to the region.

Supply Challenges

Supply challenges facing recycled water supplies include the need to address:

- Projected available wastewater supply is not adequate to fulfill future demands for recycled water.
- Changes in the future amount of available wastewater as well as increases in wastewater strength (total dissolved solids and nitrate levels) and changes in treatment resulting from trend towards more efficient indoor water use.
- The efficient use of recycled water for outdoor irrigation (both urban and agriculture) and whether this use should be consistent with existing state efficiency standards.
- Increased energy needs for treatment and delivery of recycled water.
- Increasing regulatory and environmental issues for construction and operation of recycled water systems, in particular surface recharge of recycled water.

Supply Opportunities

The IRP process identified the following list of potential projects. Potential projects range from conceptual to well-developed proposals. Each project has the ability to increase the amount of supply available for recycled water direct use and groundwater recharge.

Implications

Due to its reliability and climate resilience, recycled water is one of the most valuable water supplies for the

Table 3-4: Recycled Water Supply & Baseline Demands

	2015	2020	2025	2030	2040
Recycled Water Supply[1]	60,200	64,300	69,700	75,100	82,900
SAR Discharge Obligation[2]	17,000	17,000	17,000	17,000	17,000
Direct Use Demands[3,4]	24,700	28,800	30,700	30,700	30,700
Groundwater Recharge [3]	14,500	16,900	18,700	18,700	18,700
Remaining Recycled Water Supply	***4,000***	***1,600***	***3,300***	***8,700***	***16,500***

Notes: (1) Regional supply per Wastewater Facilities Master Plan, includes 3% loss due to treatment waste streams.
(2) Minimum discharge required by SAR Obligation is 16,850 AFY. For planning purposes, assume 17,000 AFY
(3) Per 2015 Recycled Water Program Strategy and Agency FY2015/16 TYCIP.
(4) Includes agricultural demands.

Table 3-5: Recycled Water Supplies & Projects

Recycled Water Baseline		
Project Name	**Description**	**AF**
Baseline Recycled Water for Groundwater Recharge 2015-2020	14,500 AFY by 2015 based on 5-year historical average from 2009-2014	14,500
Baseline Recycled Water Direct Use 2015-2020	16,100 AFY by 2015 based on 5-year historical average from 2009-2014	16,100
Baseline Recycled Water for Groundwater Recharge 2021-2025	2,400 AFY of additional Recycled water by 2020 for groundwater recharge per IEUA FY15-16 TYCIP	2,400
Baseline Recycled Water Direct Use 2021-2025	8,900 AFY of additional Recycled water direct use by 2020 per IEUA FY15-16 TYCIP	8,900
Baseline Recycled Water for Groundwater Recharge 2026-2040	1,800 AFY of additional Recycled water for groundwater recharge by 2025 per IEUA FY15-16 TYCIP	1,800
Baseline Recycled Water Direct Use 2026-2040	4,000 AFY of additional Recycled water for direct use by 2025 per IEUA FY15-16 TYCIP	4,000

Recycled Water Projects			
Project Name	**Description**	**ID**	**AF**
WRCRWA Recyled Water Intertie	The Western Riverside County Regional Wastewater Authority (WRCRWA) Plant intertie would allow for the delivery of recycled water from the WRCRWA Plant to be used in the IEUA southern service area. This would also allow additional recycled water to be delivered into the northern service area groundwater recharge basins by reducing the demand from the RP-1 930 pressure zone pump station. Intertie would occur within the 800/930 Pressure Zones.	9	4,500
Rialto Recycled Water Intertie	The Rialto intertie project would allow for delivery of recycled water from the Rialto Wastewater Treatment Plant (WWTP) to be used in the IEUA service area. The intertie could occur near the RP-3 groundwater recharge basins. This concept could involve the Inland Valley Pipeline, LLC to convey water between Rialto WWTP and IEUA's recycled water distribution system. Supply could be used for direct, groundwater recharge, or other reuse strategy.	10	4,500
Pomona Recycled Water Exchange/Transfer	The City of Pomona does not currently use all of the treated effluent from the Pomona Water Reclamation Plant. One concept would involve partnering to develop and expand their recycled water facilities in exchange for an agreed amount of their Chino Basin groundwater right. Could include other supply transfer agreement such as reclaimable waste and/or groundwater.	11	2,500
RP-1 Recycled Water Injection-Increment 1, 2, 3	This project would construct an advanced water filtration (e.g. process treatment that combines micro or ultrafiltration) facility at RP-1 to further treat tertiary effluent to allow the water to be injected directly into Chino Basin. The sizing of the facility and the volume to be produced will be determined as part of the portfolio development process. Increments 1-3 facility would be sized for 7,500 AFY.	12 13 14	2,500 2,500 2,500
Satellite Recycled Water Injection-Increment 1, 2, 3	This project category would construct a satellite (outside of RP-1) wastewater treatment plant with advanced water filtration (e.g. process treatment that combines micro or ultrafiltration) to allow the water to be injected directly into Chino Basin. The location, sizing, and volume to be produced will be determined as part of the portfolio development process. Increments 1-3 facility or facilities would have a capacity of 7,500 AFY.	15 16 17	2,500 2,500 2,500
Recycled Water Direct Use Expansion-Increment 1, 2, 3, 4	IEUA developed a new Recycled Water Program Strategy concurrent with the IRP. This project category will be used to determine the potential interest in expanding the direct use system beyond IEUA's Ten Year CIP. Includes the reuse of regional wastewater supply, approximately 83,000 AFY by 2035, and potential recycled water interties. Each increment would increase direct use beyond baseline supply by 5,000 AFY. Increment 1-4 facilities would increase direct use beyond baseline supply by 20,000 AFY.	19 20 21 22	5,000 5,000 5,000 5,000
Existing Groundwater Recharge Basin Improvements beyond RMPU-Increment 1, 2, 3, 4	The 2013 Chino Basin RMPU recommended a set of preferred projects to improve recharge at the existing groundwater spreading basins. This project category represents the next increment of additional groundwater recharge (imported water and/or recycled water) capable at the existing facilities. Increment 1-4 facilities would increase recharge at existing basins within the Chino Basin by an additional 15,000 AF.	23 24 25 26	2,500 2,500 5,000 5,000

Table 3-6: Recycled Water Projects Continued

Recycled Water Projects (*continued*)			
Project Name	**Description**	**ID**	**AF**
Construct New Groundwater Recharge Basins-Increment 1, 2, 3, 4	Purchase land to construct new groundwater recharge basins in the service area to capture additional stormwater, recycled water, and/or imported water for groundwater recharge. Increment 1-4 would provide up to an additional 9,800 AFY of recharge capacity, which is approximately 4 new basins at 350 AF per month for 7 months of operation.	27 28 29 30	2,450 2,450 2,450 2,450
Direct Potable Reuse-Increment 1, 2	This project would construct an advanced water filtration and treatment (e.g. process treatment that combines micro or ultrafiltration) facility at a Regional Plant. The treatment process would allow the recycled water to be introduced into the potable water system. Increment 1+2 facility would have a capacity of 10,000 AFY.	60 61	5,000 5,000
RP-1 NRWS Treatment	The north Non-Reclaimable Wastewater System (NRWS) discharges approximately 3.5 MGD of brine to Los Angeles County annually. The project would construct a treatment facility to allow the Region to reuse this supply into the recycled water system. Requires plant expansion and partial reverse osmosis for blending.	65	3,920
Watershed Wide Water Transfers	This category of projects will construct or arrange other water transfers external to the Chino Basin. For example, dry weather flow exchange of recycled water to Orange County Water District for an equivalent amount of purchased imported water. For the purposes of the IRP, it is assumed that this category of projects will not increase supply, but will increase reliability and/or quality. To occur annually or intermittently. Resiliency and flexibility benefit only.	98	5,000 AF
Chino Basin Water Transfers	This category of projects will construct or arrange other water transfers within the Chino Basin. Projects to also include inter-agency interties for increased reliability. For the purposes of the IRP, it is assumed that this category of projects will not increase supply, but will increase reliability. To occur annually or intermittently.	99	5,000 AF

region and is a high priority for additional investment. The region needs to account for the trend towards increased indoor water efficiency and evaluate opportunities to bring in supplemental wastewater flows through construction of collection systems in non-sewered areas and collaboration with neighboring jurisdictions to optimize regional infrastructure. Further, the region needs to improve efficiency of direct recycled water use to maximize its availability to all Agencies. This is particularly important for outdoor irrigation as improved efficiency can help make more recycled water available during the summer and fall when demands for recycled water are at their highest.

Implications for recycled water supplies:

- Are not impacted by climate making recycled water the region's most climate resilient water supply.
- Are needed to maximize supplemental water for groundwater recharge.
- Are generated locally and can be beneficially used by all Agencies.
- Are critical to improving the region's water self-reliance and reducing dependence on climate variable supplies such as imported water.
- Are being impacted by indoor water efficiency trends so the region must anticipate the amount of supply that is likely to be available in the future and the changes in treatment that may be required to maintain the water quality of these supplies.
- Are a supplemental water source for the entire region with infrastructure that can be intertied with that of neighboring agencies to optimize availability and use of recycled water.
- Generally require a higher level of energy than other water supplies for treatment and distribution, but are less energy intensive than imported water supplies and use of this water can contribute to statewide reductions in greenhouse gas emissions.

CHINO BASIN DESALTER

Resource Overview

The Chino Basin Desalter Authority (CDA) was formed to manage the production, treatment, and distribution of highly-treated potable water to cities and water agencies throughout the southern Chino Basin. A Joint

Powers Agency, the CDA was formed by the Jurupa Community Services District; Santa Ana River Water Company; Western Municipal Water District; the Cities of Chino, Chino Hills, Norco, and Ontario; and the Inland Empire Utilities Agency to treat saline groundwater extracted from the southern portion of the Chino Basin. Saline water is water that has more salt (about 1000 ppm of total dissolved solids) than fresh water, but not as high as seawater (about 3000 ppm of total dissolved solids).

The CDA operates two desalters: Chino I Desalter which began operation in 2001 and Chino II Desalter which began operation in 2006. The treatment processes at the Chino I and Chino II Desalters include Reverse Osmosis (RO) and Ion-Exchange (IX) for removal of nitrate and total dissolved solids (TDS). The Chino I Desalter also includes air stripping for removal of volatile organic chemicals (VOC).

These facilities serve three purposes. First, they convert unusable groundwater into a reliable potable water supply for the region and are part of a long-term pollution cleanup strategy for the Chino Basin. Second, they provide hydraulic control over the lower Chino Basin, which prevents the migration of poor quality water into the Santa Ana River as well as downstream impacts on groundwater basins in Orange County. Third, they maintain and enhance groundwater yield for the Chino Basin.

The Desalters are a critical component of a long-term salinity management strategy that enables the region to use recycled water in the Chino Basin. The Peace Agreement, OBMP, and Maximum Benefit Plan approved by the Santa Ana Regional Water Quality Board and the State Water Resources Control Board require ongoing implementation of regional salt management and reduction actions as a condition of the regional recycled water use permits for outdoor irrigation as well as for groundwater recharge. CDA accounts for approximately 5% of the regional water supply portfolio.

Baseline Supply

Chino I Desalter and Chino II Desalter currently produce 25,000 AFY of treated groundwater. These facilities are being expanded and will have the capacity to treat 35,200 AFY by 2017. The amount of water received by member agencies within IEUA's service area is approximately 50% of the total production from these facilities. The remaining water is sent to agencies within the Western Municipal Water District service area.

Member agencies that receive water from the Desalter facilities within IEUA's service area are:

- City of Chino
- City of Chino Hills
- City of Ontario

Based on information from the CDA, the baseline Chino Desalter supply for the Agency's service area is assumed to be 17,300 AFY through 2040.

Climate

The effect of climate on water supply produced from the Chino Desalter facilities was not modeled as part of the IRP. Climate impacts were considered to be negligible as the quantity of water produced is dependent upon the capacity of the desalter facility and is not supply limited.

Supply Challenges

Supply challenges facing the Chino Desalters include the need to address:

The outstanding groundwater replenishment obligation to the Chino Basin of 152,900 AF through the duration of the Peace Agreement that must be fulfilled by the region.

Increased energy needs and costs for the expanded treatment of saline water and brine disposal

The location of Desalter production wells near existing contamination plumes in the groundwater basin, including potential costly impacts on Desalter treatment processes as well as opportunities to use the Desalters as part of a groundwater clean-up strategy.

Supply Opportunities

The IRP process identified of potential projects that are listed in Table 3-7. Each project has the ability to increase the amount of supply available, treated, or produced by the Desalter facilities.

Implications

The Chino Desalters provide a new source of potable water supplies for the region by treating currently unusable groundwater, as well as providing hydraulic control of the southern Chino Groundwater Basin. This infrastructure is critical to the continued use of recycled water in the region as well as improving groundwater quality and yield in the Chino Basin.

Key implications for the Chino Desalter water supplies:

- Are not impacted by climate.
- Are critical to improving the region's water self-reliance and reducing dependence on climate variable supplies such as imported water.
- Generally require a higher level of energy than other water supplies for treatment and distribution.
- Are an essential component of the regional commitment to remove salt and nitrates in the Chino Basin.
- Are critical to the continued use of recycled water in the region for groundwater recharge.
- Provide hydraulic control for the Chino Basin which prevents poor quality water from migrating into the Santa Ana River and downstream groundwater basins.
- Are managed under the Peace Agreement and the Optimum Basin Management Plan, which require fulfillment of a groundwater replenishment obligation of 152,900 AF.
- Are limited on the amount of water that can be produced based on the capacity and performance of the Desalter facilities.

LOCAL SURFACE WATER

Resource Overview

Agencies located in the northern part of the region have long standing legal rights to divert and treat water from local creeks in the Santa Ana River watershed, including San Antonio Canyon, Cucamonga Canyon, Day Creek, Deer Creek, Lytle Creek, and other small surface creeks and tunnels. The amount of water from these local surface supplies is variable, depending on climate conditions, and currently accounts for approximately 5% of the regional water supply portfolio.

The quality of local surface water is typically quite high as the creeks are filled by rainfall and snowmelt from the San Gabriel Mountains. However, the surface water must receive treatment to comply with state and federal drinking water quality standards before it can be served for public use. Large storm events can cause sedimentation levels to rise to levels that impact the water treatment plants. During these times, water is bypassed downstream where it may be available for groundwater recharge.

Baseline Supply

The most recent local surface water production data received from Agencies was used to forecast the baseline water supply. The amount of local surface water supply was established using a 5-year average of production during the period of FY2009-10 through

Table 3-7: Chino Basin Desalter Baseline & Projects

Baseline Chino Desalter Projects		
Project Name	**Description**	**AF**
Baseline Chino Desalter	Phase 2 Chino Basin Desalter production for IEUA service area	15,000 AF
Baseline Chino Desalter	Phase 3 Chino Basin Desalter production for IEUA service area	2,730 AF

Chino Desalter Projects			
Project Name	**Description**	**ID**	**AF**
Desalter Recovery Improvement	The existing Chino Basin I Desalter (CD-1) recovers approximately 75 percent of water. Improvements could be done to increase recovery to approximately 90 percent. This water would be conveyed through the existing potable water system.	18	1,500 AF

FY2013-14. This period of time includes 3 consecutive years of below average precipitation and 2 years of normal or above normal precipitation, providing a conservative projection. Baseline local surface water before considering climate modeling effects is therefore assumed to be 11,700 AFY through year 2040.

Climate

Local surface supplies are highly impacted by climate. Due to their dependence on precipitation and snow melt, the amount of water that can be obtained from local surface sources is highly variable from year to year.

Historical variability in local surface supplies is highly correlated with precipitation but also temperature. Annual surface water supplies are highly dependent on the weather and susceptible to changes in climate and were modeled under climate influences. Based on the results of the climate simulations, the projected baseline local surface water supplies available between 2015 and 2020 ranges from 2,000 to 12,600 AFY.

Local surface supplies may also be impacted by temperature. Higher temperatures cause more evaporation, reducing the amount of soil moisture. This means that the soil is more likely to absorb and hold water when rain occurs and this can reduce the amount of water flowing into creeks and streams.

Records indicate that local surface flows have declined and projections indicate that flows will decline in the near future from at least 2021 to 2040 (Seager 2012).

Supply Challenges

Supply challenges facing local surface water supplies include the need to address:

- High variability due to their dependence on rainfall and snow melt .

Supply Opportunities

The IRP process identified potential projects listed in Table 3-8. Each project has the ability to increase the amount of supply available from local surface water by either diversion and/or treatment improvements.

Implications

Local surface water, when available, is an extremely valuable resource because it is considered relatively "free", with the cost to the Agencies being the operation of the necessary facilities to capture and use this water. Where possible, use of local surface water should be maximized.

Key implications for local surface water supplies:

- Are generated locally and are the region's least energy intensive water supply and have minimal greenhouse gas emissions relative to imported water .
- Are cost effective relative to imported water supplies.
- Are highly dependent on weather and driven by climate.
- Will be significantly reduced during droughts when below average precipitation and drier conditions exist.
- Are a high quality water supply and provide a supplemental source of water to blend with and improve groundwater quality.
- Are highly variable and require facilities to operate under a wide range of flows .

NON-CHINO BASIN GROUNDWATER

Resource Overview

Member agencies pump groundwater from basins adjacent to the Chino Basin. These basins include Cucamonga, Rialto, Lytle Creek, Colton, and the Six Basins groundwater basins. The Six Basins are comprised of the Ganesha, Live Oak, Pomona, Lower Claremont Heights, Upper Claremont Heights and Canyon Basin. These basins currently provide approximately 10% of the regional water supply portfolio.

There are four agencies within the IEUA service area that include non-Chino groundwater as a water supply source. These agencies are the City of Upland, Cucamonga Valley Water District, Fontana Water Company, and San Antonio Water Company.

Baseline Supply

The most recent water production data was used to forecast the baseline water supply. The amount of non-

Chino Basin groundwater supply was based on a five-year production average from FY2009-10 to FY2013-14. Baseline non-Chino groundwater supply is assumed to be 22,000 AFY through 2040.

Climate
Climate effect on non-Chino Basin groundwater was not evaluated as part of the IRP. However, it is expected that climate will have a slight impact on these groundwater supplies based on the climate simulations performed on the Chino Basin. The non-Chino Basin groundwater baseline supply is assumed to remain constant at 22,100 through 2040.

Supply Challenges
These groundwater basins face similar supply challenges to those identified for the Chino Basin. Challenges include reduced natural infiltration, safe yield operating constraints, and water quality issues.

Supply Opportunities
The IRP process identified the following list of potential projects. Each project has the ability to increase the amount of supply available for groundwater recharge and/or increased groundwater production.

Implications
Groundwater basins outside of the Chino Basin face similar implementation hurdles as the Chino Basin.

Key implications for non-Chino Basin groundwater supplies:

- Are not impacted by climate once water is stored in the groundwater basin.
- Are slightly impacted by receiving reduced natural recharge within the basin resulting from climate and/or development impacts.
- Can be sustained or increased through use of supplemental water for groundwater recharge (through in lieu or direct recharge) when these resources are available.
- Are a vital local emergency resource to help mitigate abnormal or catastrophic events through additional groundwater production.
- Provide a means for sustainable regional water management by enabling exchanges and transfers among agencies within the watershed.
- Are generated locally and are the region's least energy intensive water supply and have minimal greenhouse gas emissions relative to imported water.
- Are cost effective relative to imported water supplies.
- Are critical to improving the region's water self-reliance and reducing dependence on climate variable supplies such as imported water.
- Reduce the water resource needs in the Chino Basin.

IMPORTED WATER

Overview
IEUA was originally formed in 1950 as a municipal wholesale water district for the purpose of providing municipalities in the Chino Basin with supplemental

Table 3-8: Local Surface Water Baseline & Projects

Baseline Local Surface		
Project Name	Description	AF
Baseline Local Surface	11,700 AF based on 5-year historical average from 2009-2014.	11,700 AF

Local Surface Projects			
Project Name	Description	ID	AF
Dry Weather Flow Diversions	Capture and treat urban dry weather flow from Chino, Cucamonga and San Sevaine Creek into the Regional Plants. For the purposes of the IRP, a volume of 3,500 AFY was assumed as total available dry weather flow.	48	3,500 AF
Maximize Local Surface Water	This category of projects will construct facilities needed to capture additional local surface water. Projects to be defined by IEUA's Agencies. For example, increase surface flows off Lytle Creek in wet years. Assume benefit 3 in 5 years.	88	1,000 AF

imported water purchased from the Metropolitan Water District of Southern California (MWD).

MWD is a contractor to both the State Water Project (SWP), which imports water from northern California, and Colorado River Aqueduct (CRA) systems. The availability of imported water supplies is heavily dependent on hydrology and environmental regulations. This dependency can lead to high variability in the annual amount of water available to the Southern California region. For example, in the midst of the great drought, the California State Water Project was able to supply only 5 percent of its contract allocation in 2013-2014, which is a significant reduction from past allocations.

Due to salinity management concerns in the Chino Basin, the region can only use imported water from the State Water Project. Imported purchases from MWD in recent decades have averaged about 70,000 AFY, providing about 30% of the water supply for the service area.

Imported water purchased from the MWD is limited by a purchase order agreement. The agreement allows the region to purchase up to a total of 93,283 AF per year at its lowest (Tier I) rate. This limit is based on historical imported water purchases for municipal use by the member agencies and for regional groundwater recharge. The agreement includes an annual minimum purchase commitment of 39,835 AF. Note that this amount is slightly less than the 40,000 AFY minimum needed for the operation of the region's water treatment facilities.

There are four water treatment plants that treat imported water purchased from the MWD. These treatment facilities include:

- Water Facilities Authority's Agua de Lejos Treatment Plant (81 mgd capacity)
- Fontana Water Company's Sandhill Surface Water Treatment Plant (29 mgd capacity)
- CVWD's Lloyd W. Michael Water Treatment Plant (60 mgd capacity)
- CVWD's Royer-Nesbit Water Treatment Plant (11 mgd capacity)

Each agency is allocated an annual portion of MWD's available Tier 1 water supply (shown below). The allocations do not confer a contractual right to MWD imported water but are used to determine the price paid for the water. Purchases in excess of the Tier 1 allocation are assessed by MWD at a higher Tier 2 rate.

- Water Facilities Authority - 31,384 AFY
- Cucamonga Valley Water District - 28,368 AFY
- Fontana Water Company - 10,000 AFY
- Inland Empire Utilities Agency/Chino Basin Watermaster – 23,531 AFY

Imported water currently accounts for approximately 25% of the regional water supply portfolio. The amount available to IEUA and/or the Chino Basin Watermaster is used only for groundwater recharge.

Baseline Supply

The baseline supplies for imported water are based on IEUA Resolution 2014-12-1. Supplies were set as follows:

- Current imported purchases by Agencies are assumed to be 65,000 AFY (consistent with FY2014/15 purchases).
- Imported water purchases between 2020 and 2040 are assumed to be 69,752 AFY.
- Minimum imported purchases are assumed to be 40,000 AFY to meet retail agency water treatment operational requirements .

Climate

The State Water Project's infrastructure was designed to capture snowmelt from snowpack in the Sierra Nevada Mountains. When the snow melts during the warmer spring months, this combination of reservoirs and conveyance facilities provides a steady water supply throughout the year but especially during the summer and fall when water demands peak and precipitation is limited.

However, climate change is expected to continue to significantly impact the timing and characteristics of snowpack on which the SWP system depends. Predicting MWD's ability to supply specific amounts of imported water to IEUA were beyond the scope of climate simulation. Instead, the IRP considered a wide range of potential changes in imported supply availability,

Table 3-9: Non-Chino Basin Groundwater Supplies & Projects

Non Chino Basin Groundwater Baseline		
Project Name	**Description**	**AF**
Baseline Non-Chino Groundwater	22,100 AF Amount of water produced by an Agency from outside the Chino basin	22,100 AF

Non Chino Basin Groundwater Projects			
Project Name	**Description**	**ID**	**AF**
Maximize Other Groundwater	This project category will identify Agency projects that would result in additional groundwater production benefits coming into the IEUA service area outside of the Chino Basin. Such projects may have the potential of an additional 5,000 AF.	63	5,000 AF

including assumptions in which SWP supplies decline by 2040. To explore a range of possible climate effects of MWD supplies, the analysis varied the amount of reduction of the Tier 1 water above the minimum purchase level. Two levels were selected—a 40% reduction and an 80% reduction. This corresponds to a range of reduction of 17% to 34% in total MWD Tier 1 supplies.

An interesting finding from the climate modeling was the identification of times, particularly in the next ten years, when imported MWD water may not be needed to meet regional demand. This water, if purchased, could be placed into the Chino Basin for storage and made available during future droughts, or catastrophic events (see Figure 3-11). The modeling also shows that beyond the first ten years there are periods when there is shortage in the MWD supply, and available water is lower than the baseline assumption.

Supply Challenges
Supply challenges facing imported water supplies from MWD and the SWP include the need to address:

- Catastrophic interruption—for example, an earthquake affecting the Delta or Tehachapis, or a break along the Delta levee, MWD feeder, or pump station.
- Maintenance interruptions—for example, Rialto line repairs.
- Operational constraints without improvements to the Bay Delta conveyance, such as the Delta Fix proposed by the Department of Water Resources.
- Colorado River over-allocation and the status of Lake Mead, including the potential impact on availability of MWD supplies which could constrain distribution of water from the State Water Project.
- Cost of MWD supplies that are expected to increase 4-5% annually during the next decade.
- Vulnerability to climate change conditions, such as warmer temperatures, reduced snowpack, and more frequent droughts that will reduce supplies available from CRA and SWP given that both infrastructure projects are designed to capture slow melting snowpack.

Supply Opportunities
Additional opportunities for increasing supplemental water supplies from imported sources, both through MWD and from other locations, were identified during the IRP process and are summarized in Table 3-10.

Implications
Climate conditions, conveyance reliability, and the need to improve SWP infrastructure all affect the future availability of imported water to the region. Due to its high quality, including having low TDS, SWP water should be purchased when it is available to enhance groundwater recharge and to leverage other water supply programs that benefit the region.

Key implications for imported water supplies:

- Are less reliable now than they have been in the past and may further decrease in reliability with climate change and continued uncertainty about infrastructure improvements.
- Are not fully reliable, and it will be important to develop alternative supplies so that the region has the flexibility to withstand reduced SWP supply caused by extended years of limited/reduced snowpack.
- Are not fully reliable, and so additional investments may need to be made to meet water quality restrictions if low-salinity imported water is not available, such as considerations to include CRA supply.
- Should be leveraged, when available in the near-term, by the region for storage, groundwater recharge, exchanges, transfers, or in-lieu.
- Will be more expensive. The cost of supplies is expected to increase 4-5% annually during the next decade .

CONSERVATION

Overview

Unlike traditional water supplies, efficient use of water reduces demand in ways that are quantified indirectly. Demand is reduced through changes in consumer behavior and savings from water-efficient fixtures like toilets and showerheads. These water savings come from both "active" and passive "code-based" conservation efforts. "Active" efforts are Agency funded programs such as rebates, installations, and education. "Code-based" conservation consists of demand reductions attributable to more water-efficient plumbing codes and appliance standards and from customer response to higher water costs and rates that encourage water efficiency.

Over the past 24 years, since signing the 1991 California Urban Water Conservation Council's (CUWCC) memorandum of understanding (MOU) regarding Urban Water Conservation, the region has been committed to developing and implementing conservation programs that serve as a key component in the overall water resource management portfolio for the region. Such active conservation programs have traditionally included rebates for water saving devices such as ultra-low-flow toilets and high efficiency clothes washers, which are primarily administered through MWD's "Save Water-Save A Buck" program for commercial, residential, and multi-family properties. Other programs include educational programs such as the award-winning

Figure 3-11: Potential Climate Change Impact on SWP Supplies

Table 3-10: Imported Water Baseline & Projects

Baseline Imported Water		
Project Name	Description	AF
Baseline Imported Water	Agencies can purchase up to 69,750 AFY per the Member Agency Tier 1 purchase limit per Resolution 2014-12-1	69,750 AF

Imported Water Projects			
Project Name	Description	ID	AF
Existing Groundwater Recharge Basin Improvements beyond RMPU-Increment 1 ,2, 3, 4	The 2013 Chino Basin RMPU recommended a set of preferred projects to improve recharge at the existing groundwater spreading basins. This project category represents the next increment of additional groundwater recharge (imported water and/or recycled water) capable at the existing facilities. Increment 1 and 2 would increase recharge at existing basins within the Chino Basin by 2,500 AFY each. Increments 3 and 4 are 5,000 AF each. If all increments are selected there is a potential of up to 15,000 AFY of production.	23 24 25 26	2,500 AF 2,500 AF 5,000 AF 5,000 AF
Construct New Groundwater Recharge Basins-Increment 1, 2, 3, 4	Purchase land to construct new groundwater recharge basins in the service area to capture additional stormwater, recycled water and/or imported water for groundwater recharge. Each increment would provide up to an additional 2,450 AFY of recharge capacity, which is approximately one new basin at 350 AF per month for 7 months of operation. If all increments are selected, there is a potential production of 9,800 AFY.	27 28 29 30	2,450 AF 2,450 AF 2,450 AF 2,450 AF
ASR wells MZ1 and MZ2	Construct aquifer storage and recovery (ASR) wells to increase imported water groundwater recharge within management zone 1 and 2. Reference projects were taken from the 2010 RMPU, Sections 6.7.2.1 and 3 for CVWD and the City of Ontario.	31	11,500 AF
ASR wells MZ3	Construct ASR wells to increase imported water groundwater recharge within management zone 3. Reference projects were taken from the 2010 RMPU, Sections 6.7.2.2 for JCSD.	32	3,500 AF
Maximize ASR wells	Construct other ASR wells to increase imported water recharge by 3,500 AFY within the Chino Basin during wet and dry years. Assume benefit 40% of the time (2 in 5 years). Storage to be dependent on supplemental water availability in wet years.	33	3,500 AF
Cadiz IW Transfer	The Cadiz project would allow for the import of unused groundwater from the remote Fenner Valley near Cadiz, California. For the purposes of the IRP, a 5,000 AFY increment of water is assumed. The Cadiz supply would be transferred and taken as SWP water into the Chino Basin.	34	5,000 AF
Secure SWP IW transfer outside MWD	Imported water supply is solely from MWD via the SWP and is limited by the Agency's purchase order. Other permanent, temporary or seasonally available imported water supplies could be purchased and wheeled into the Chino Basin. The volume of water available varies depending on the source of water and timing. Supplies could be purchased from various Irrigation Districts or secured via Ag Transfer. Assume benefit 1 in 10 years.	35	5,000 AF
SBVMWD IW Transfer	As a SWP contractor, San Bernardino Valley MWD (SBVMWD) has a Table A allocation. This option would involve constructing an intertie between SBVMWD's imported water system. The supply would be temporary or seasonally available and could be purchased and wheeled into the Chino Basin. Assume benefit 1 in 5 years.	36	5,000 AF
Ocean Desalination Exchange	This project category would involve a partnership with another water agency pursuing ocean water desalination; through in-lieu exchange, the Chino basin would obtain an agreed amount of imported water. For the purposes of the IRP, a volume of 5,000 AFY was chosen. Opportunity to invest in upcoming ocean desalination plants includes Huntington Beach, Carlsbad and West Basin.	37	5,000 AF
Water Banking Facility	This project category would invest into the Semitropic Groundwater Storage Bank in Kern County or similar program. The Chino Basin could bank additional purchases of wet year water when these supplies are available and Chino Basin facilities are capacity limited.	56	5,000 AF

Table 3-10: Imported Water Baseline & Projects *(continued)*

Imported Water Projects (*continued*)			
Project Name	**Description**	**ID**	**AF**
Max Tier 1 MWD Imported Water-Increment 1, 2, 3	Maximize imported water from MWD at Tier 1 rate. Total available supply at Tier 1 rate is 93,283 AFY or cumulative purchase order maximum of 932,830 AF through December 31, 2024. Supply can be taken directly, in-lieu or for supplemental recharge. Each increment would allow for the purchase of an additional 7,850 AFY. If all increments are selected up to 23,550 AFY could be purchased purchased annually or intermittently.	89	7,850 AF
		90	7,850 AF
		91	7,850 AF
Max Tier 2 MWD Imported Water-Increment 1, 2, 3	Maximize imported water from MWD at Tier 2 rate. Could be taken annually or intermittent, availability pending MWD supply. Supply can be taken directly, in-lieu or for supplemental recharge. Each increment would allow for the purchase of an additional 5,000 AFY . If all increments are selected up to 15,000 AFY could be purchased annually or intermitently.	92	5,000 AF
		93	5,000 AF
		94	5,000 AF
MWD Replenishment or discount wet year water-Increment 1, 2, 3	Maximize replenishment or discount wet year imported water from MWD. Availability pending MWD supply and pricing. Supply can be taken in-lieu or for supplemental recharge. Each increment would allow for the purchase of an additional 10,000 AFY. If all increments are selected up to 30,000 AFY could be purchased annually or intermittently. Assumes benefits after 2 consecutive wet years (approx. 1 in 15 years)	95	10,000 AF
		96	10,000 AF
		97	10,000 AF
Watershed Wide Water Transfers	This category of projects will construct or arrange other water transfers external to the Chino Basin. For example, dry weather flow exchange of recycled water to Orange County Water District for an equivalent amount of purchased imported water. For the purposes of the IRP, it is assumed that this category of projects will not increase supply, but increases reliability and/or quality. To occur annually or intermittent. Resiliency and flexibility benefit only	98	5,000 AF
Chino Basin Water Transfers	This category of projects will construct or arrange other water transfers within the Chino Basin. Projects to also include inter-agency interties for increased reliability. For the purposes of the IRP, it is assumed that this category of projects will not increase supply, but increases reliability. To occur annually or intermittent.	99	5,000 AF

Garden in Every School Program, National Theatre for Children, monthly water conservation tips, landscape audits, and turf-grass removal programs.

Water conservation, also called water use efficiency strategies, have changed dramatically over the past few years as a result of state and local policies that require increased conservation and improved efficiency, technological improvements that increase water savings potential, and advancements in methods of communication that provide new opportunities to engage and educate the public. To address the shift, regional efforts include securing funding for technology-based software and supporting the development of sustainable water rate structures. Both technology-based software and sustainable rate structures establish an efficiency standard for each individual customer based on their existing indoor and outdoor water use profile. These programs also have the added benefit of targeting outdoor water use, which accounts for approximately 60% of urban M&I demands.

Baseline Supply

Conservation baseline supplies are water savings from existing conservation programs' active and passive savings. Baseline conservation savings are embedded in the demands forecast, based on current annual savings (see Table 3-11). These programs are expected to continue through 2040.

Climate

Climate does not appear to impact water supply savings from conservation.

Supply Challenges

Supply challenges facing conservation programs include the need to address:

- Existing development will need incentives such as conservation rebates to meet state regulations.
- Existing development will also need targeted messaging based on state established efficiency standards to meet responsible water use and establish a new water use practices.

"And it never failed that during the dry years the people forgot about the rich years, and during the wet years they lost all memory of the dry years. It was always that way."

—John Steinbeck
East of Eden

- Current efficiency standards do not include recycled water use.

Supply Opportunities
The IRP process identified potential projects that are listed in Table 3-11. Efficiency savings beyond baseline are shown as new water supplies because they offset water demands. Conservation project savings are tied to the IRP's upper demand forecast; therefore if actual demands are lower, there will be a corresponding reduction in projected water savings.

Implications
This is a key climate resistant water supply that has the best potential to augment and extend current available supplies. Since outdoor irrigation makes up 60% of urban M&I demands, this supply category has the largest potential impact for the region. The region will need to evaluate how to achieve targeted efficiency goals.

Key implications for water conservation programs:

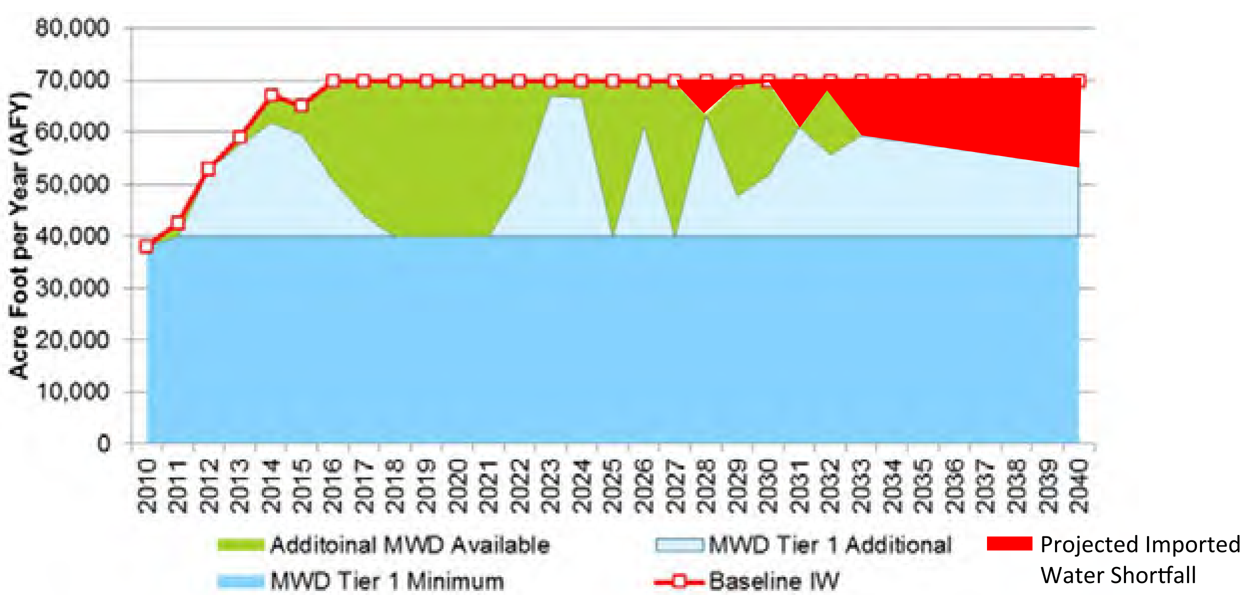
- Are cost effective relative to imported water supplies.
- Extend other water supplies and delay the need for additional system expansion because it is a demand offset.
- Are instrumental for the region to reduce dependence on climate variable supplies such as imported water.
- Are not impacted by climate change or water quality concerns.

Table 3-11: Water Use Efficiency Baseline & Projects

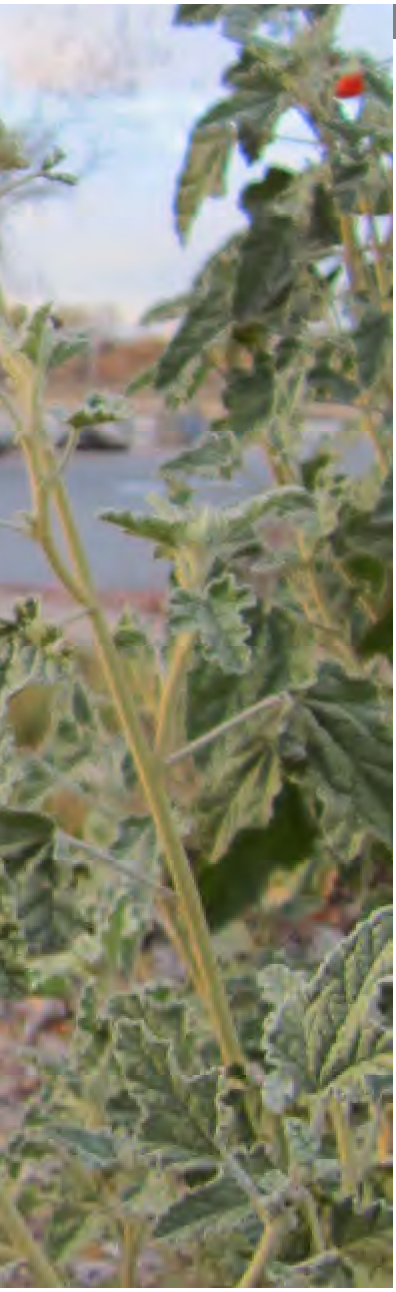
Water Use Efficiency Baseline		
Project Name	**Description**	**AF**
Baseline Conservation	1,000 AF per year from existing conservation programs' active and passive savings.	1,000 AF

Water Use Effiency Projects			
Project Name	**Description**	**ID**	**AF**
Expand WUE Devices	Implement additional targeted device related savings to reduce demand beyond current annual water use efficiency (WUE) savings. Provide incentives and pilot programs to roll out extremely high efficient indoor fixtures and toilets. To be verified with Water Use Efficiency Business Plan (WUEBP).	39	5,000 AF
WUE - Turf Removal-Increment 1, 2, 3	Implement turf removal and landscape transformational programs to reduce outdoor demand. To be verified with WUEBP. Each increment would provide up to 5,000 AFY of savings. If all are selected, they can result in up to 15,000 AFY savings	40 41 42	5,000 AF 5,000 AF 5,000 AF
WUE - Budget Rates-Increment 1, 2, 3	Implement water budget based rates for 2 Agencies (assuming 15% total savings per Agency after 3 years). To be verified with WUEBP. Each increment would provide up to 13,350 AFY of savings. If all increments are selected, they can result in up to 40,050 AFY savings.	43 44 45	13,350 AF 13,350 AF 13,350 AF
WUE- Recycled Water Demand Management-Increment 1, 2	Implement demand management devices and programs for direct recycled water customers. Does not generate additional supply, aids in managing the supply during peak demand. Each increment would provide 2,500 AF of demand management. If both are selected they could provide 5,000 AFY additional recycled water. This supply could be used for increasing direct use demands, groundwater recharge or other reuse strategy	46 47	2,500 AF 2,500 AF
WUE - Advanced Metering Technologies	Install advanced metering infrastructure (AMI) between retail meters and a utility provider. Will provide real-time data about consumption and allow customers to make informed choices about usage.	66	5,000 AF

Figure 3-12: Sample Model Run of Climate Impacts on Imported Water Supply Availability



4. Supply Portfolio Themes



Baseline Assessment

Single Variable Tests

Water Resource Strategies

The desert globemallow, which requires very little water, grows in a low water use landscape.

Supply Portfolio Themes

Section 4 presents the different water resource strategies developed through the IRP Technical Work Group. The purpose of each water resource strategy is to increase future water supplies, including water efficiency as a source of supply, to reduce the region's vulnerability to climate change and to ensure that future water needs for the region are met.

First, a baseline assessment was conducted to evaluate the ability of the baseline water supplies, established in Section 3, to meet projected baseline water demands. To do this, a water management mass balance model was developed by IEUA's technical consultants (see Appendix 2) to compare projections of water demand and supply under historical and future climate change conditions. Three demand scenarios were then evaluated across 106 different projections of future climate derived from two archives of downscaled global circulation models simulations. The results were reviewed to assess the extent to which baseline water supplies could NOT fulfill demands (described as supply shortfalls) under each future. This baseline assessment provided the foundation for the Work Group to identify the additional water resources needed to meet future demands.

Next, single variable tests were conducted to determine how well specific types of new water supplies could help the region meet projected demands under climate change. Single variable tests added individual supplies to the baseline to determine how well that single change performed under each of the 106 climate scenarios in the model.

Based on the outcomes of the single variable tests, the IRP Technical Work Group crafted 5 water resource strategies for further evaluation. Each strategy had an underlying theme, such as maximizing the use of recycled water or securing additional supplemental water supplies for groundwater replenishment. These 5 strategies were turned into project portfolios by selecting representative projects from proposed lists of future projects (see Section 3) that could be implemented to increase future water supplies above the baseline projections.

Finally, the performance of each water resource strategy was compared to the baseline assessment. The evaluation focused on two IRP criteria: (1) the ability of the scenario to generate sufficient water to meet future regional water demands under climate change conditions and (2) the amount of surplus water produced, defined as water not needed to meet demand, and placed into long-term groundwater storage.

BASELINE ASSESSMENT

The regional baseline supplies and demand projections were developed in the first part of the IRP planning process. To establish how this baseline could be impacted by climate change, these projections were modeled and stress-tested under 106 separate climate scenarios, as referenced above and included in Appendix 2.

As a reminder, each of the 106 climate scenarios yields an independent model result and is depicted with a separate colored line in the figures below. Note that no one run is "more accurate" than another. However, some of the runs stand out as "outlying" results that are either higher or lower than the majority of the runs. These results are not included in the scenario evaluations. For the purposes of the IRP, the analysis focused on the range of results for the majority (75%) of the climate scenarios.

Figure 4-1 shows the amount of unmet demand through 2040 under the baseline assessment with climate change. For the purposes of the IRP, unmet demands are defined as those times when demands exceed available water supplies. For the baseline conditions with climate change, the range of unmet demand is 0 AFY to 60,000 AFY. Note that the amount of unmet demand is smaller in the near term (about 20,000 AFY by 2030) and increases to 60,000 AFY by 2040. It is also important to note that without additional water supply development the region would struggle to meet future

Figure 4-1: Baseline Unmet Demands

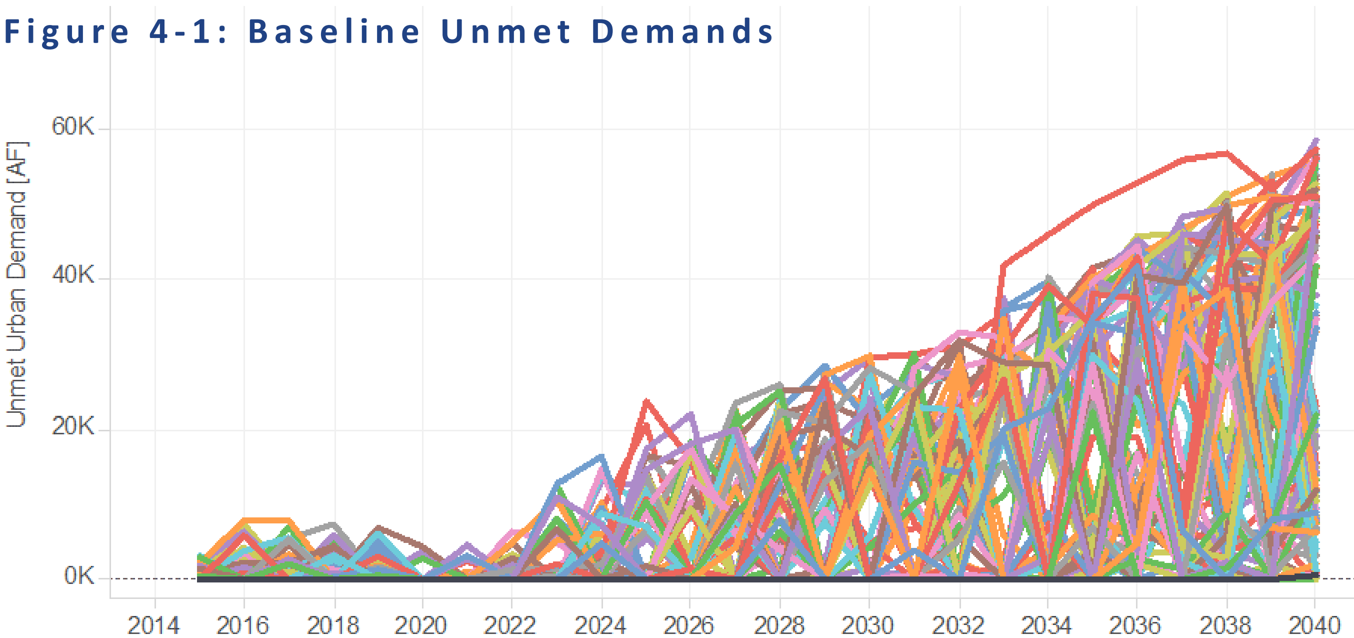


Figure 4-2: Baseline Stored Water Balance

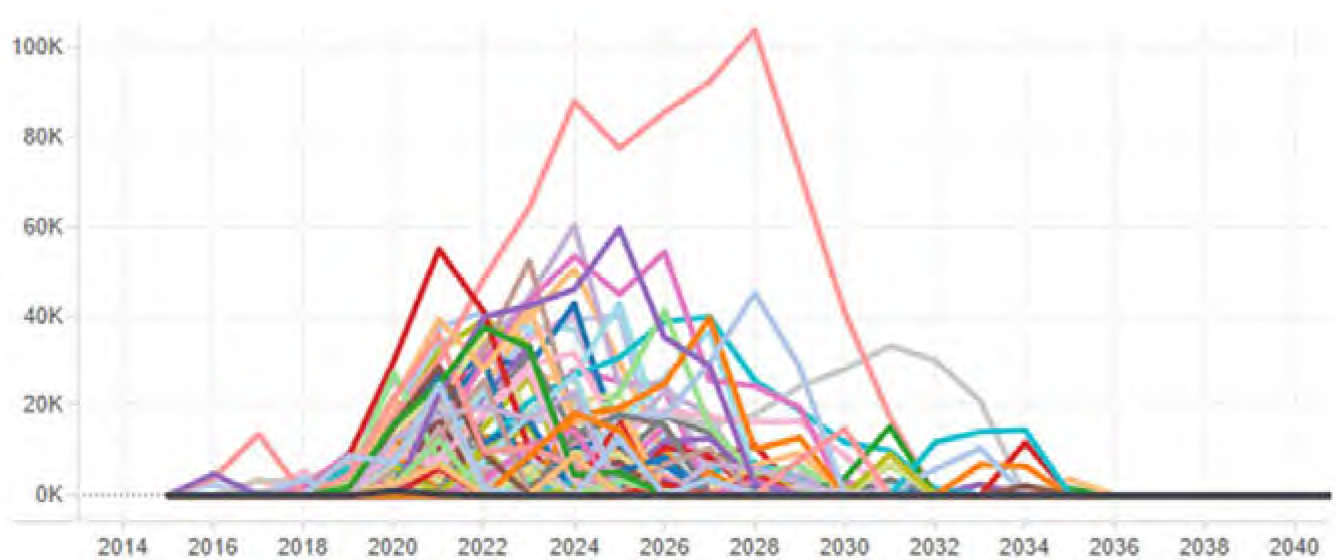


water demands under climate change conditions.

In each climate run, there may be periods when water supplies exceed demands, creating surplus water supplies. The WEAP model tracks these surplus supplies by allocating the water to a groundwater storage account.

The IRP uses the 2014 groundwater storage level as the baseline for tracking the addition of surplus water to groundwater storage. Similarly, during periods when demands exceed supplies, the model deducts water from groundwater storage tracking account but cannot lower the groundwater below its 2014 level.

Figure 4-2 illustrates how stored water accumulates under each climate scenario through 2040. A positive or upward slope on the graphic indicates water surplus conditions and the excess water is added to the storage tracking account. A negative, or downward slope, indicates that demand is exceeding supplies, and water is pulled out of storage to meet, in whole or in part, the excess demands. As a result, the stored water creates a buffer supply that can be used offset future shortfalls. The model shows "unmet demands" only when demands exceed supplies AND no water remains in the storage tracking account created by the model.

For comparison, the thick black line in Figure 4-2 represents baseline assessment conditions without climate change. Note there is no accumulation of surplus supplies and therefore all available water supplies are needed to meet the regional demand, and no water is stored for future use.

Results of the baseline assessment with climate change indicate that the following is likely to be experienced by the region:

- 79% of the regional water demands are met by 2040.
- Water supply shortages, or unmet demand, will be more intense and frequent under climate change.
- Climate will drive unmet demand to 25,000 AFY by 2030 and up to 60,000 AFY by 2040.
- Significant water supply shortfalls could occur as soon as 2022.
- A "do nothing" approach is not sustainable, as projected demands exceed supplies under all scenarios.
- It may be possible to accumulate additional groundwater under baseline conditions, but the amount would depend on future climate scenarios (e.g., more rainfall, less variability, cooler temperatures) than currently predicted.

SINGLE VARIABLE TESTS

To evaluate how the addition of a new water supply could enhance the region's current, or baseline water supplies under climate change, a series of four single variable tests were evaluated. These tests were used to determine the potential improvement of implementing an isolated or single water supply source to help improve baseline conditions impacted by climate change.

The four single variable tests are:

1. Maximizing the Use of Prior Stored Chino Basin Groundwater
2. Maximizing the Purchase of MWD Imported Water
3. Maximizing Recycled Water Supply for Groundwater Recharge
4. Reducing Urban Water Demand by Increased Conservation and Water Use Efficiency

Conclusions from comparing the tests to the baseline assessment are summarized below.

1 — Maximizing the use of prior stored Chino Basin groundwater.
Test 1, Maximizing the Use of Prior Stored Chino Basin Groundwater does not produce new water supplies because it relies only on prior (pre-2013) stored groundwater. It is assumed that up to 8,400 AFY of groundwater can be pumped above baseline levels, and that the total amount of additional groundwater pumping cannot exceed 280,000 AF.

Results of this test are illustrated in Figure 4-3. If the region only relies upon the addition of prior stored Chino Basin groundwater to meet future water resource needs:

- 91% of regional demands are met by 2040.
- Water supply shortages, or unmet demands, will be moderately improved by 2040 over baseline conditions.
- Unmet demand would be reduced to approximately 18,000 AFY by 2030 and 40,000 AFY by 2040.
- Significant water supply shortfalls could occur as early as 2024.
- The approach is not sustainable given that a significant amount of prior stored groundwater is needed to meet regional demands through 2040. The median of the climate scenarios shows a reduction in this storage from 280,000 AFY to approximately 130,000 AFY by 2040, with scenarios dropping as low as 80,000 AF.
- It may be possible to accumulate more stored water under this strategy, but the amount would depend on more benign future climate scenarios (e.g., more rainfall, less variability, cooler temperatures) than currently predicted.

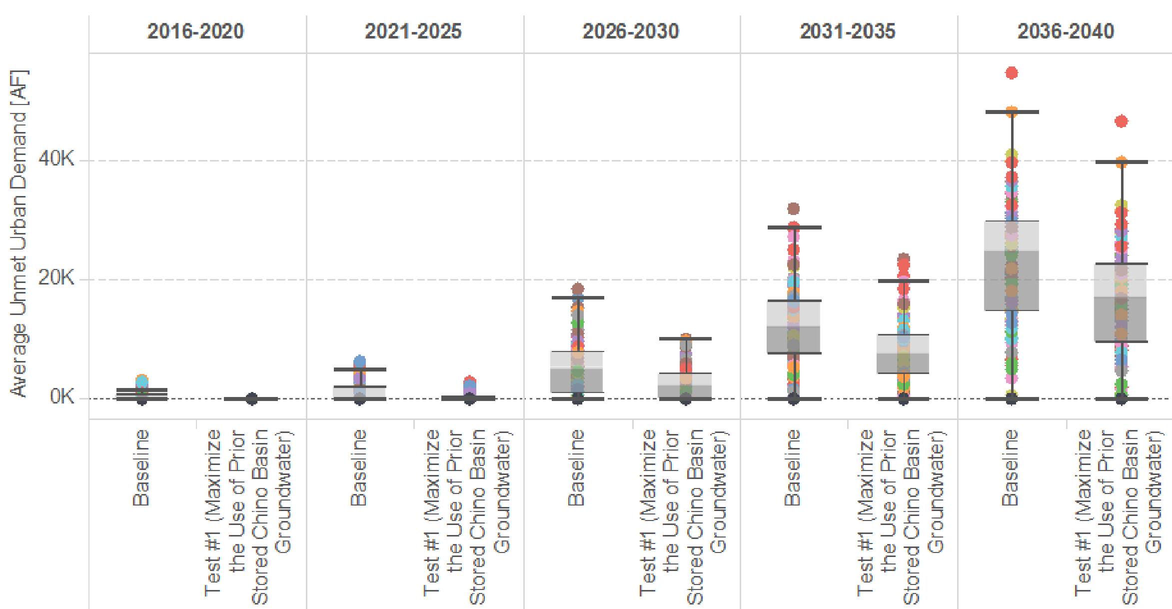
2 – Maximizing the Purchase of Metropolitan Water District (MWD) Imported Water

IEUA member agencies (agencies) have the ability to purchase up to 70,000 AFY of imported water from the MWD. As discussed in Section 3, the baseline modeling assumption for imported water is that member Agencies could purchase up to 69,752 AFY (consistent with Resolution 2014-12-1), with a minimum total purchase of 40,000 AFY.

Due to the cost of imported water, agencies typically only purchase the amount of water needed to meet their operational requirements or fulfill water demands that cannot be met through local supplies. This means there may be times when agencies don't need the imported water but could decide to purchase this water and place it into storage for future use.

The approach of Maximizing the Purchase of MWD imported water does not add new imported water supplies to the baseline supply. However, the region's agencies will purchase all of the water available, up to 70,000 AFY. This purchase would occur even if water supplies exceed demand. In years where agencies make these purchases, the additional water would be put into storage via groundwater recharge or in-lieu of

Figure 4-3: Baseline vs Test 1 Unmet Demand Comparison



groundwater pumping. The quantity of supply would be dependent on imported water availability.

Results of this test are illustrated in Figure 4-4. If the region relies only upon maximizing imported water purchases to meet future needs:

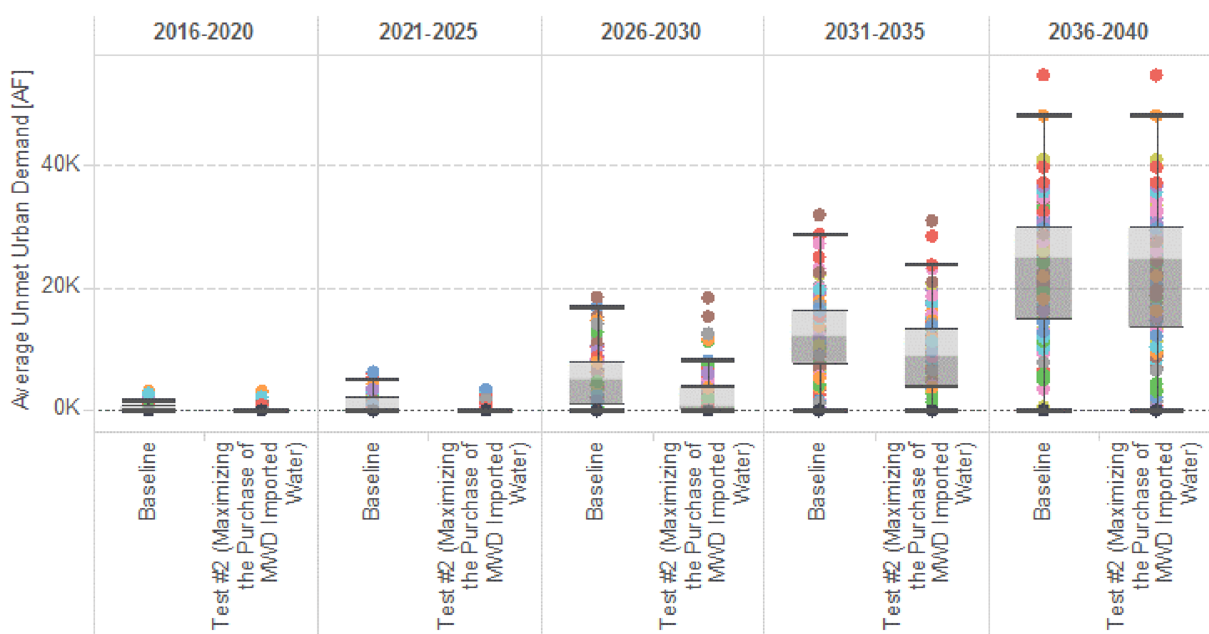
- 85% of regional demands are met by 2040.
- Water supply shortages, or unmet demands, will be slightly improved by 2040 over baseline conditions because imported water availability is adversely impacted by climate change.
- Unmet demand would be reduced to 22,000 AFY by 2030 and 55,000 AFY by 2040.
- Significant water supply shortfalls could occur as soon as 2024.
- This approach is not sustainable as a stand-alone approach and must be combined with other water resources to improve water supply conditions for the region.
- It may be possible to accumulate more stored water under this strategy, but the amount would depend on more benign future climate scenarios (e.g. more rainfall, less variability, cooler temperatures) than currently predicted.
- This approach could increase the region's dependence on imported water supplies, which could make the region more vulnerable to climate change.

3 – Maximizing Recycled Water Supply for Groundwater Recharge

The region has developed a successful regional Recycled Water Program for both direct use (landscaping, agricultural irrigation and industrial processing uses) and indirect use (groundwater recharge). In 2000, the region identified recycled water as a critical resource needed for drought-proofing the region and maintaining its economic growth.

The approach of Maximizing Recycled Water Supply for Groundwater Recharge builds on the successful regional Recycled Water Program. As discussed in Section 3, the baseline assumption for available recycled water is 47,700 AFY by 2025. As the region continues to grow, new communities will be sewered and additional recycled water supplies will be generated. It is estimated that there will be approximately 85,500 AFY of recycled water supply from regional development by 2040.

Figure 4-4: Baseline vs Test 2 Unmet Demand Comparison



Therefore, this will deliver 37,800 AFY of additional recycled water to the groundwater recharge program.

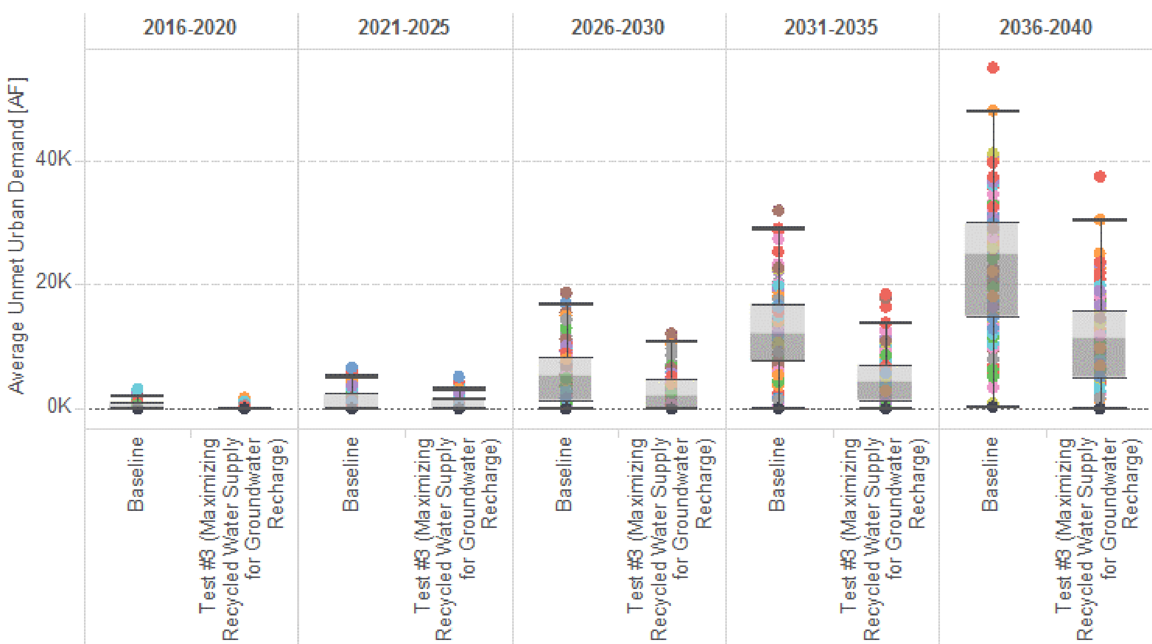
Results of this test are illustrated in Figure 4-5. If the region relies only upon maximizing recycled water supply for groundwater recharge for future water needs:

- 95% of the regional demands are met by 2040.
- Water supply shortages, or unmet demand, will be greatly improved by 2040 over baseline conditions.
- Unmet demand would be reduced to 10,000 AFY by 2030 and 17,000 AFY by 2040.
- Although water supply shortfalls are reduced, they could occur as early as 2024.
- Maximizing recycled water for groundwater recharge is sustainable as a stand-alone strategy, but would provide greater benefits if combined with other programs to enhance water supply conditions for the region.
- Provides flexibility by maximizing the amount of water stored in the Chino groundwater basin for future use.
- Recycled water is the most climate resilient water supply available to the region.
- It may is possible to accumulate more stored water under this strategy, but the amount depends on more benign future climate scenarios (e.g. more rainfall, less variability, cooler temperatures) than currently predicted.
- The volume of future recycled water supply is impacted by the amount and timing of new development in the region and indoor water efficiency trends. Additional tracking of wastewater flows is needed to accurately anticipate the amount of recycled water that will be available by 2040.

4 – Reducing Urban Water Demand by Increased Outdoor Water Use Efficiency and Conservation
Approximately 60% of the region's urban water use is for outdoor irrigation, particularly lawns. The IRP Technical Work Group requested a scenario to evaluate the implications of an increased outdoor efficiency and conservation program.

The approach of Reducing Urban Demand by Increasing Water Use Efficiency assumes that the region achieves a level of water savings that will reduce residential outdoor water usage to levels consistent with the requirements of the Department of Water Resources State Model Water Efficiency Landscape Ordinance (AB

Figure 4-5: Baseline vs Test 3 Unmet Demand Comparison



1881). This could be achieved by programs such as budget-based rates and continuation of active conservation programs. The region currently has one water agency on budget based rates.

This test assumed that four retail agencies would implement budget based rates structures by 2020. The savings are estimated to be 27,000 AFY from the rate structure changes and 11,000 AFY from active potable and recycled water conservation programs. Combined these measures are assumed to reduce urban demands by approximately 17% from 2013-14.

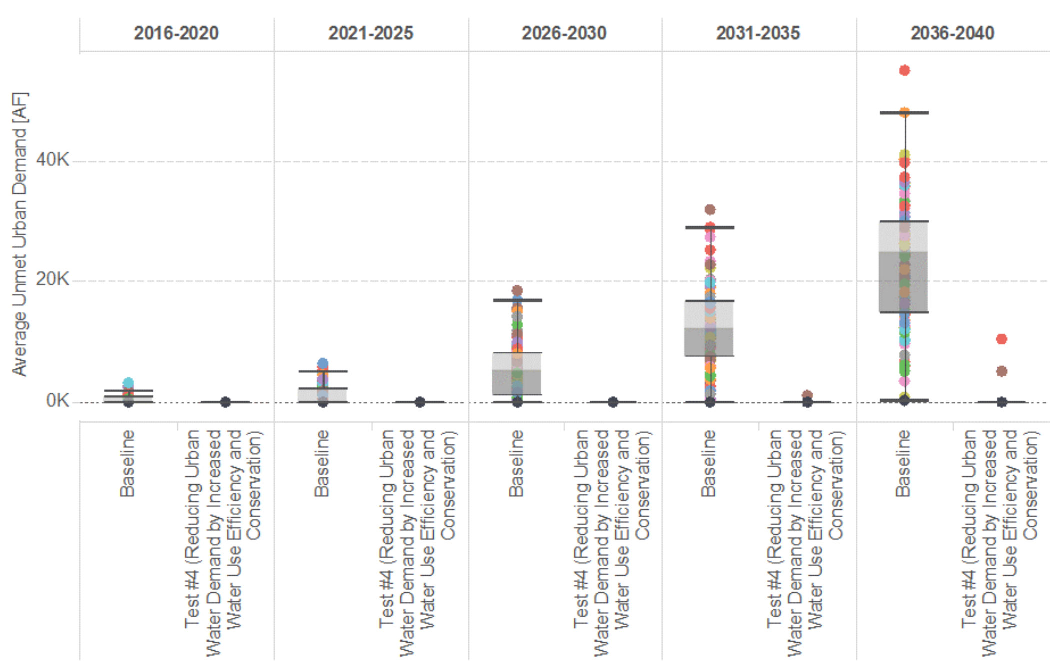
Results of this test are illustrated in Figure 4-6. If the region relies upon only reducing urban water demand by Increased Outdoor Water Use Efficiency and Conservation to meet future water needs:

- 100% of the regional demands are met by 2040.
- Water supply shortages, or unmet demand, would be eliminated by 2040.
- Water supply shortfalls are delayed beyond 2040.
- Accumulation of stored water is very likely to occur, with more than 50% of the climate scenarios producing over 200,000 AFY of stored water by 2040.
- Regional recycled water supplies would not be impacted because this approach targets outdoor conservation.
- Reduces dependence on climate dependent supplies and reduces the volume of additional water supplies needed to meet future demand.
- Requires expansion of water efficiency programs to support transition to budget based rate structure to achieve outdoor efficiency standards.

Single Variable Test Conclusions
Results from the four single variable tests show that all of the strategies helped to reduce and delay water supply shortages when compared to baseline conditions under climate change. Notably, water efficiency/ conservation is the only water supply approach that could eliminate water supply shortages through 2040 as a "stand-alone" approach. However, the expansion of local supplies such as recycled water and storm water ensures that the region is insulated from unforeseen or cataclysmic conditions.

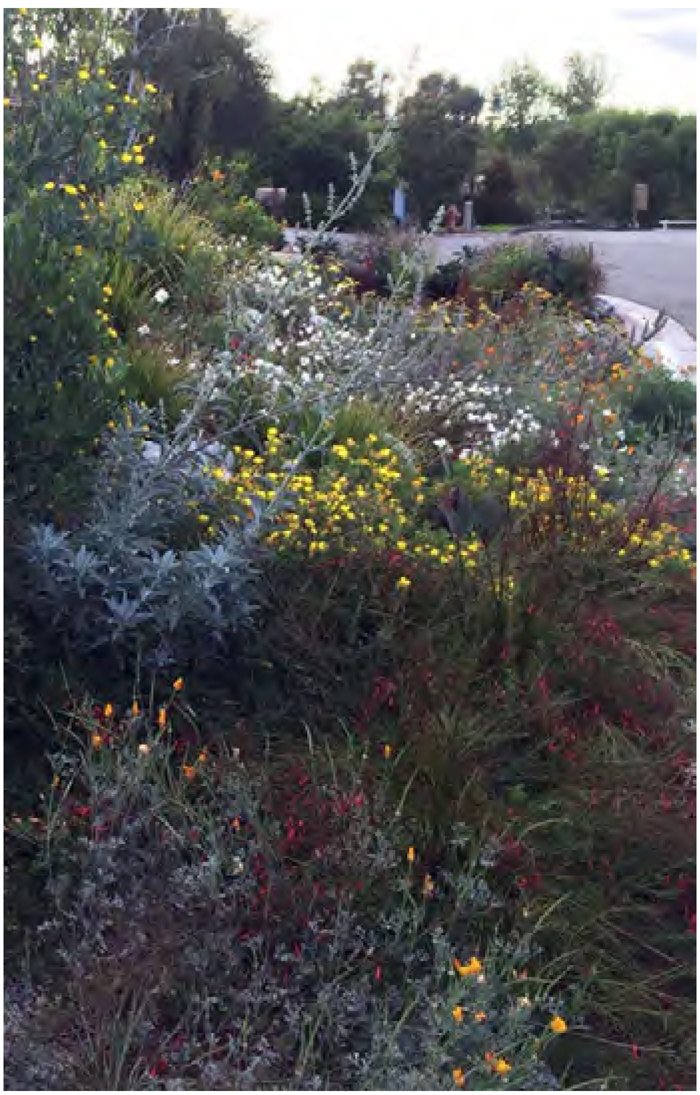
The recommended approach in the IRP is to diversify the region's water supplies. The following conclusions were

Figure 4-6: Baseline vs Test 4 Unmet Demand Comparison



used as the basis for developing the next step in the IRP, the creation of water strategies:

- Water use efficiency and conservation provides the region with the greatest level of water supply reliability and resiliency.
- Diversification of region's water supplies minimizes the potential for water shortages under climate change and from catastrophic events.
- Increasing water supplies for Chino groundwater recharge increases storage and provides a supply buffer, enhancing the region's water supply flexibility and resilience.
- Implementing outdoor water use efficiency and conservation minimizes climate change impacts on urban water demand.



WATER RESOURCE STRATEGIES

Each water resource strategy is a combination of water supply and conservation projects or opportunities that the region could pursue to achieve the goals of the IRP. Five water resource strategies were developed during the course of the IRP workshops, with a total of eight project portfolios. Each portfolio was modeled to determine performance and resiliency across the 106 climate scenarios. These strategies and portfolios are as follows:

Strategy A – Increase Chino Basin Groundwater Production

- ***Portfolio 1**:* Maximize the Use of Prior Stored Groundwater

Strategy B– Recycled Water Program Expansion

- ***Portfolio 2:*** Maximize Recycled Water (Including External Supplies) and Local Supply Projects and Implement Minimal Water Efficiency
- ***Portfolio 3:*** Portfolio 2 Plus Secure Supplemental Imported Water from MWD and Non-MWD Sources

Strategy C– Recycled Water & Water Efficiency Program Expansions

- ***Portfolio 4:*** Maximize Recycled Water (Including External Supplies) and Implement Moderate Water Efficiency
- ***Portfolio 5:*** Portfolio 4 Plus Implement High Water Efficiency

Strategy D– Increase Groundwater Recharge Supplies

- ***Portfolio 6*:** Maximize Supplemental Water Supplies and Recycled Water Supplies

Strategy E – Maximize Imported Water Supplies with Moderate Water Efficiency

- ***Portfolio 7***: Maximize the Purchase of Imported Water from MWD and Implement Minimal-Moderate Level of Water Efficiency
- ***Portfolio 8***: Portfolio 7 Plus Maximize Recycled Water

Table 4-1: Supply Totals for Portfolio 1

MWD	69,750	-
Other		-
WUE [(2)]	1,000	-
add'l supplies subtotal		*8,400*
Total Water Supply	**283,550**	**291,950**

Notes:

(1) Baseline Supply of 18,700 GWR + 29,000 Direct + 17,000 SAR, or total of 64,700 AFY, based on Agency TYCIP and not total available wastewater supply. Estimated total available local RW supply by 2040 to be 85,550 AFY based on 2015 WWFMPU flow monitoring.

(2) Baseline WUE of 1,000 AFY already included in the Urdan Demand forecast. Therefore, not included in Supply Table to avoid double counting. Only new WUE in addition to Baseline to be counted in Total Supply.

Strategy A – Increase Chino Basin Groundwater Production (Portfolio 1)

Under Strategy A, the IRP Technical Work Group explored the implications of expanding groundwater production without bringing in additional water resources. Strategy A is similar to Single Variable Test 1 – Maximizing the Use of Prior Stored Chino Basin Groundwater. It includes capacity building projects, the use groundwater that was previously stored in the Chino Basin, and the implementation of water efficiency programs for direct recycled water customers. Although strategy this does not generate additional recycled water supply, it allows for additional recycled water to be used for groundwater recharge. One water supply portfolio, Portfolio 1, was developed for Strategy A, with additional supply amounts shown in Table 4-1.

Portfolio 1 assumes that an additional 8,400 AFY of groundwater supply would be pumped from the Chino Basin, with a 2040 “not-to-exceed” limit of 280,000 AF. Since new supplies in Portfolio 1 are limited to 8,400 AFY from stored Chino Basin groundwater the results are identical to the first test strategy. Implicit in this scenario, when there are periods where the portfolio’s water supplies exceed demands, the resulting surplus water supplies is assumed to be recharged into the groundwater basin. When this occurs, the stored water can be used at a later time.

Figure 4-7 shows unmet demands for Portfolio 1 in comparison to the baseline model run. Potential shortfalls begin to appear around 2022, which is the same as the baseline. In the majority (75%) of model runs, Portfolio 1 reduces unmet demands by 2040 from up to 27,900 AFY to 12,500 AF.

Stored water balances are shown in Figure 4-8. As illustrated, groundwater balances begin to accumulate in Portfolio 1 by 2020 with storage peaking around 2025. Stored groundwater starts to be used to meet demands by 2028 and continue to be drawn down through 2040.

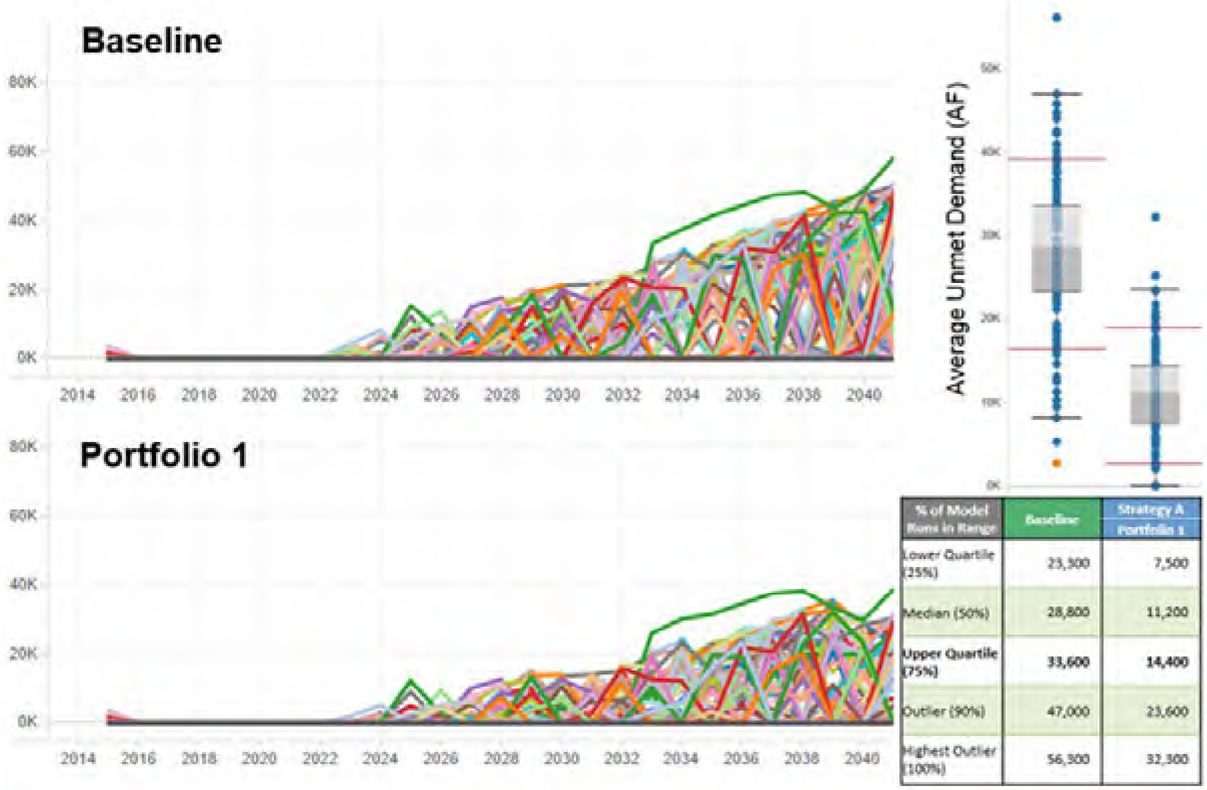
In summary, Portfolio 1

- Provides 95% of the demands under majority of climate scenarios
- Shows a 5% improvement over baseline conditions by utilizing existing stored groundwater on an annual basis
- However, the groundwater pulled from storage is a finite resource and due to the continued drawdown, this strategy is not sustainable without additional projects to replenish the storage or reduce demands.

Strategy B– Recycled Water Program Expansion (Portfolios 2 & 3)

Under Strategy B, the IRP Technical Work Group explores the continued expansion of the recycled water program. Strategy B focuses on how achieving a 40% increase in recycled water supply over the baseline condition would benefit the region. The strategy accomplishes this goal by using an additional 17,000 AFY of locally generated recycled water. As mentioned in Section 3, these additional recycled water supplies will be available as growth occurs in the service area. In addition, this strategy secures 10,500 AFY of external recycle water supply from neighboring jurisdictions by

Figure 4-7: Unmet Demands of Portfolio 1 Compared to Baseline



% of Model Runs in Range	Baseline	Strategy A Portfolio 1
Lower Quartile (25%)	23,300	7,500
Median (50%)	28,800	11,200
Upper Quartile (75%)	33,600	14,400
Outlier (90%)	47,000	23,600
Highest Outlier (100%)	56,300	32,300

Other		-	4,900
WUE [(2)]	1,000	5,000	5,000
add'l supplies subtotal		*32,500*	*45,250*
Total Water Supply	**283,550**	**316,050**	**328,800**

Notes:

(1) Baseline Supply of 18,700 GWR + 29,000 Direct + 17,000 SAR, or total of 64,700 AFY, based on Agency TYCIP and not total available wastewater supply. Estimated total available local RW supply by 2040 to be 85,550 AFY based on 2015 WWFMPU flow monitoring.

(2) Baseline WUE of 1,000 AFY already included in the Urdan Demand forecast. Therefore, not included in Supply Table to avoid double counting. Only new WUE in addition to Baseline to be counted in Total Supply.

2040. Strategy B also includes 5,000 AFY of additional device based conservation savings.

Two water supply portfolios were developed for Strategy B. The first, Portfolio 2, models the additional water supplies as described above. The second, Portfolio 3 includes all of Portfolio 2 supplies plus additional imported water as shown in Table 4-2. Imported water supplies include MWD Tier 1 and/or wet year purchases of supplemental water for groundwater replenishment. A complete list of projects in Portfolios 2 and 3 can be found in Appendix 6.

Figure 4-10 shows unmet demands for Portfolio 2 in comparison to the baseline model run. Potential shortfalls for Portfolio 2 begin to appear around 2024, which is two years later than baseline conditions. In the majority of model runs, Portfolio 2 reduces unmet demands by 2040 from to 27,900 AFY to 9,000 AF.

Stored groundwater balances for Portfolio 2 are illustrated in Figure 4-10. Groundwater balances begin to accumulate by 2018 with the majority of the model runs building around 25,000 AFY or less of stored water. By 2040 the quantity of stored water is depleted in approximately 90% of the climate runs.

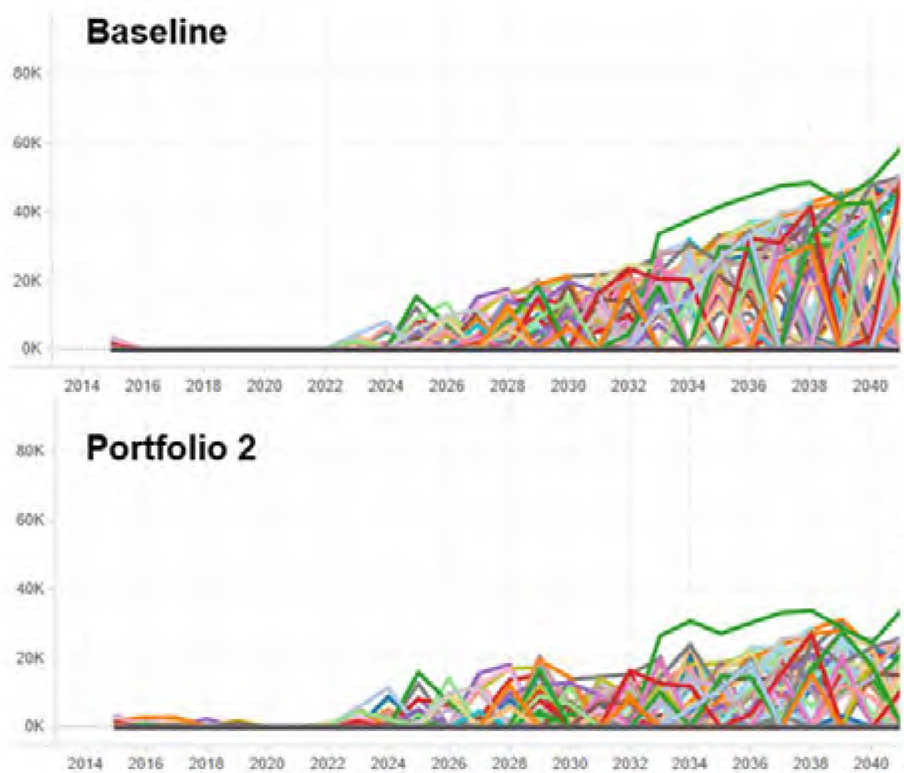
Unmet demands for Portfolio 3 in comparison to the baseline model run are shown in Figure 4-11. Potential shortfalls for Portfolio 3 begin to appear after 2035, 13 years after the baseline condition. In the majority of model runs, Portfolio 3 reduces unmet demands in 2040 from 27,900 AFY to 9,000 AF.

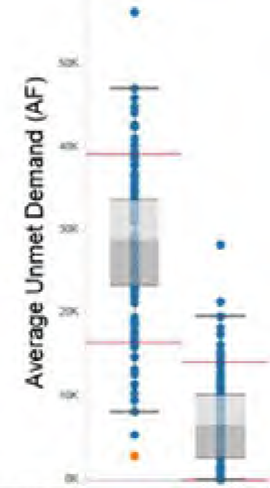
Stored water balances for Portfolio 3 are illustrated in Figure 4-12. Portfolio 3 behaves in a similar fashion to Portfolio 2, however there is a much greater probability of accumulating stored water. Approximately 70% of the runs in Portfolio 3 have water in storage by 2040. The range of stored water falls between 0 AFY and 280,000 AF.

In summary, Portfolios 2 and 3 under 75% of the climate scenarios:

- Provide 90% supply reliability under majority of climate conditions.
- Show a 5% improvement over baseline conditions by utilizing existing stored groundwater on an annual basis
- Water supply shortfalls are delayed by two years as compared to baseline conditions.
- Extend the ability to produce water stored water, with the majority of climate runs having the ability to build and maintain stored supplies through 2040

Figure 4-9: Unmet Demands of Portfolio 2 Compared to Baseline





% of Model Runs in Range	Baseline	Strategy [illegible] Portfolio 2
Lower Quartile (25%)	23,300	2,500
Median (50%)	28,800	6,600
Upper Quartile (75%)	33,600	10,000
Outlier (90%)	47,000	19,600
Highest Outlier (100%)	56,300	28,200

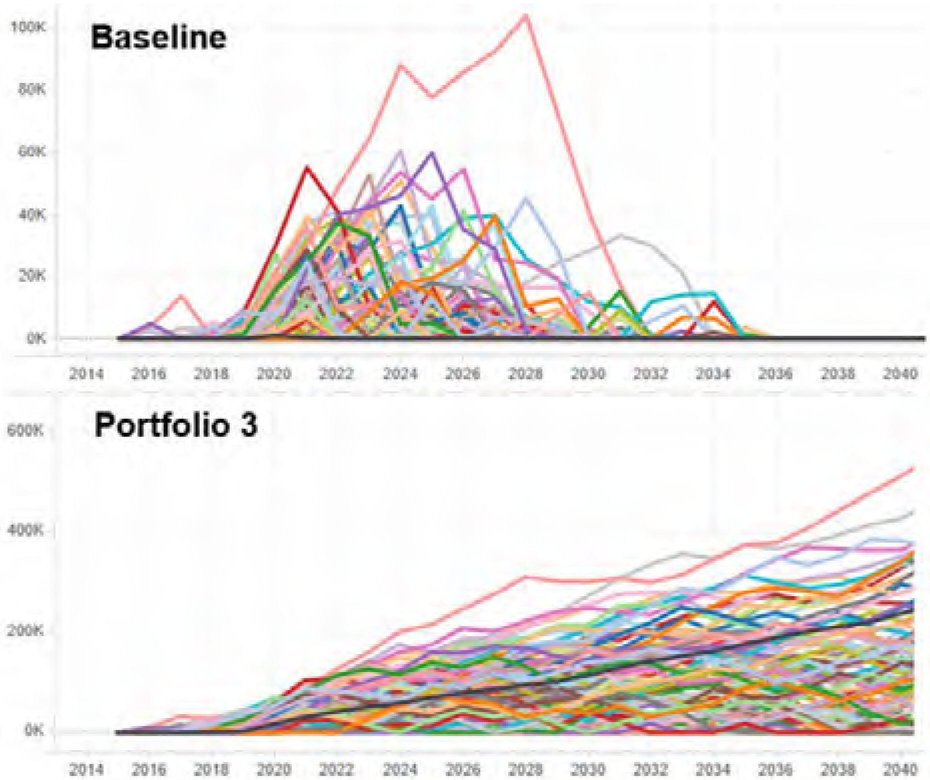
Median (50%)	28,800	demands met
Upper Quartile (75%)	33,600	2,500
Outlier (90%)	47,000	6,200
Highest Outlier (100%)	56,300	26,700

Figure 4-12: Stored Groundwater Balance of Portfolio 3



Strategy C – Recycled Water & Water Efficiency/ Conservation Program Expansions (Portfolios 4 & 5)

Under Strategy C, the IRP Technical Work Group evaluated how increased recycled water and water efficiency/conservation programming could benefit the region. With the focus on outdoor irrigation efficiency, there is a signification amount of water savings that could be achieved in both existing and future developments when compared with baseline conditions.

Strategy C assumes that a minimum of four agencies within IEUA's service area are implementing budget-based rates and increasing device-based conservation programming by 2020. This strategy also increases recycled water supply by utilizing an additional 17,000 AFY of locally generated recycled water, securing 10,500 AFY of an external recycle water supply by 2040, and implementing recycled water use efficiency programs to extend supplies.

Two water supply portfolios were developed for Strategy C. The first, Portfolio 4, models the additional water supplies as described above. The second, Portfolio 5, includes all of Portfolio 4 supplies plus the addition of two additional agencies adopting budget-based rates by 2020 and the addition of supplemental imported water as shown in Table 4-3. Imported water supplies include MWD Tier 1 and/or wet year purchases of supplemental water for groundwater replenishment. A complete list of projects in the portfolios can be found in Appendix 6.

Unmet demands for Portfolio 4 are shown in comparison to the baseline conditions in Figure 4-13. Portfolio 4 meets projected demands through 2040 100% of the time.

Stored water balances are illustrated in Figure 4-14 As illustrated, groundwater balances begin to accumulate in Portfolio 4 by 2022 with the majority of model runs continuing to build stored water through 2040. By 2040, 105 of the 106 model runs accumulated a minimum of 200,000 AFY of stored water.

Unmet demands for Portfolio 5 are shown in comparison to the baseline model run in Figure 4-15. Portfolio 5 meets projected demands through 2040 100% of the time.

Table 4-3: Supply Totals for Portfolio 4 & 5

Supply Type	Baseline	Portfolio 4	Portfolio 5
Chino Groundwater	91,300	-	-
Stormwater	6,400	-	-
Recycled Water		-	-
Locally Developed[1]	64,700	17,000	17,000
External Supplies		10,500	10,500
Chino Desalter	17,700	-	-
Local Surface	22,100	-	-
Non-Chino Groundwater	11,600	-	-
Imported Water		-	-
MWD	69,750	667	667
Other		-	4,900
WUE [2]	1,000	36,700	55,050
add'l supplies subtotal		*64,867*	*88,117*
Total Water Supply	**283,550**	**348,417**	**371,667**

Notes:

(1) Baseline Supply of 18,700 GWR + 29,000 Direct + 17,000 SAR, or total of 64,700 AFY, based on Agency TYCIP and not total available wastewater supply. Estimated total available local RW supply by 2040 to be 85,550 AFY based on 2015 WWFMPU flow monitoring.

(2) Baseline WUE of 1,000 AFY already included in the Urdan Demand forecast. Therefore, not included in Supply Table to avoid double counting. Only new WUE in addition to Baseline to be counted in Total Supply.

Stored water balances for Portfolio 5 are illustrated in Figure 4-16. As illustrated, groundwater balances begin to accumulate in Portfolio 3B by 2020 with majority of model runs continuing to build stored water through 2040. By 2040, 105 of the 106 model runs accumulated a minimum of 500,000 AFY of stored water.

In summary, Portfolios 4 and 5 perform under 75% of the climate scenarios:

- Have no unmet demands across all climate scenarios due to reduced need for water
- Build water in storage consistently across climate scenarios, which could create an opportunity to sell surplus water
- Portfolio 4 has the potential for stored groundwater to build to over 200,000 AFY by 2040
- Portfolio 5 has the potential for stored groundwater to build to over 500,000 AFY by 2040

Supply Type	Baseline	Portfolio 6
Chino Groundwater	91,300	8,400
Stormwater	6,400	-
Recycled Water		-
Locally Developed(1)	64,700	20,800
External Supplies		9,000
Chino Desalter	17,700	-
Local Surface	22,100	-
Non-Chino Groundwater	11,600	2,500
Imported Water		-
MWD	69,750	667
Other		6,400
WUE (2)	1,000	13,500
add'l supplies subtotal		*61,267*
Total Water Supply	**283,550**	**344,817**

Notes:

(1) Baseline Supply of 18,700 GWR + 29,000 Direct + 17,000 SAR, or total of 64,700 AFY, based on Agency TYCIP and not total available wastewater supply. Estimated total available local RW supply by 2040 to be 85,550 AFY based on 2015 WWFMPU flow monitoring.

(2) Baseline WUE of 1,000 AFY already included in the Urdan Demand forecast. Therefore, not included in Supply Table to avoid double counting. Only new WUE in addition to Baseline to be counted in Total Supply.

Strategy D– Increase Groundwater Recharge Supplies

Under Strategy D, the IRP Technical Work Group focused on developing water supply interties with neighboring agencies in the watershed. Intermediate levels of water use efficiency/conservation are implemented in the form of two agencies adopting budget-based rates by 2020. In addition, all potential locally produced recycled water would be utilized in this strategy. One water supply portfolio, Portfolio 6, was developed for Strategy 6, with water supplies shown in Table 4-4. A complete list of projects in Portfolio 6 can be found in Appendix 6.

Unmet demands for Portfolio 6 in comparison to the baseline conditions are shown in Figure 4-17. Portfolio 6 meets projected demands through 2040 95% of the time.

Stored water balances are shown in Figure 4-18. As illustrated, groundwater balances begin to accumulate in Portfolio 6 by 2020. Due to variability in wet year supplemental supplies, stored water balances become highly variable and it is unclear whether stored water continues to build or draw down through 2040.

In summary, 75% of the time Portfolio 6:

- Eliminates unmet demand through 2040 due to reduced outdoor water demands from increased water use efficiency/conservation programming
- Has the potential to build stored groundwater through 2040, but the amount varies with climate conditions
- Takes advantage of climate resistant supplies by maximizing recycled water and water use efficiency

Strategy E – Maximize Imported Water Supplies with Moderate Conservation

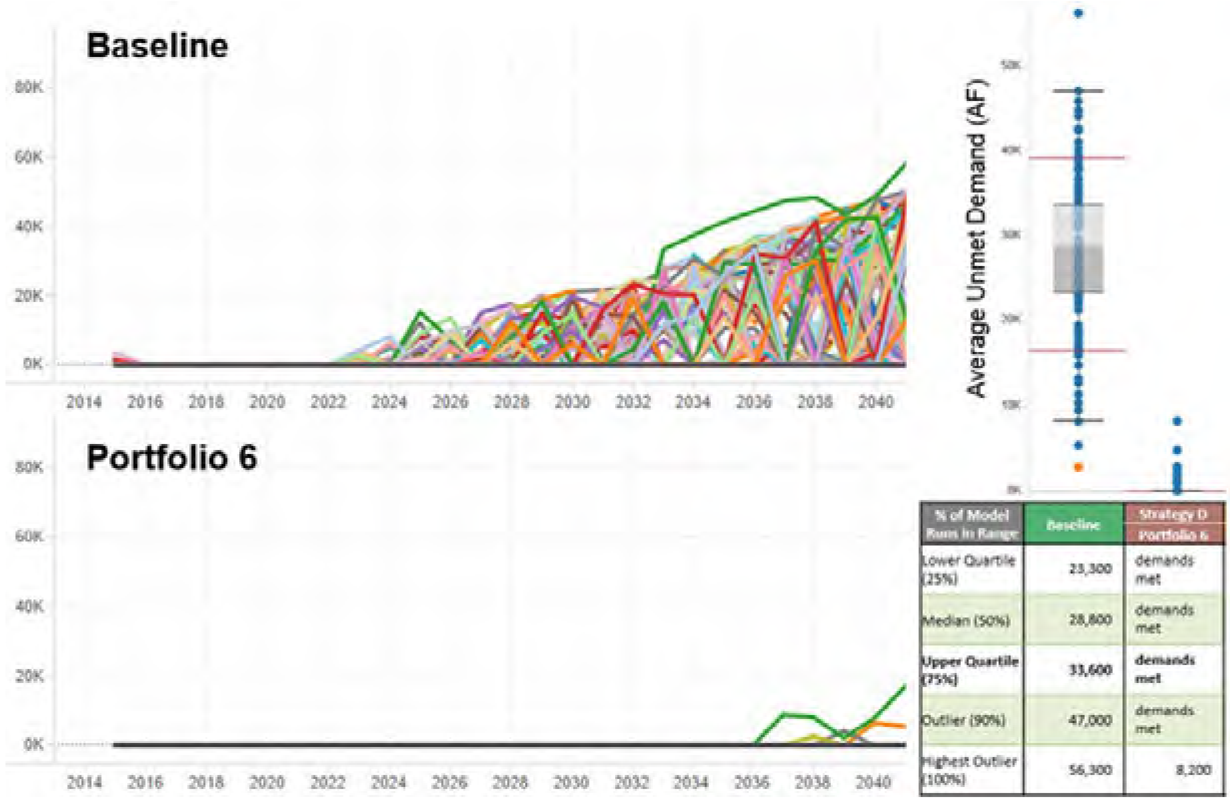
Under Strategy E, the IRP Technical Work Group evaluated how maximizing the purchase of imported water could alleviate pressure on and extend the availability of local water resources. This strategy allows for the purchase of up to 93,300 AFY of imported water to meet urban demand or to be used for groundwater replenishment. In addition, the strategy includes an intermediate level of water use efficiency/conservation in the form of two agencies adopting budget-based rates by 2020.

Two water supply portfolios were developed for Strategy E. The first, Portfolio 7, models the additional water supplies as described above. The second, Portfolio 8, includes all of the supplies of Portfolio 7 plus the addition of maximizing all locally produced recycled water as shown in Table 4-5. A complete list of projects in Portfolios 7 and 8 can be found in Appendix 6.

Unmet demands for Portfolio 7 in comparison to the baseline conditions are shown in Figure 4-19. Portfolio 7 meets projected demands through 2040 across 25% of the model runs.

Stored water balances are illustrated in Figure 4-20. As shown, groundwater balances begin to accumulate in Portfolio 7 by 2020 with the majority of model runs continuing to build stored water through 2040. Due to variability in wet year supplemental supplies, stored water balances become highly variable and unclear

Figure 4-17: Unmet Demands of Portfolio 6 Compared to Baseline



% of Model Runs in Range	Baseline	Strategy D Portfolio 6
Lower Quartile (25%)	23,300	demands met
Median (50%)	28,800	demands met
Upper Quartile (75%)	33,600	demands met
Outlier (90%)	47,000	demands met
Highest Outlier (100%)	56,300	8,200

Figure 4-18: Stored Groundwater Balance of Portfolio 6

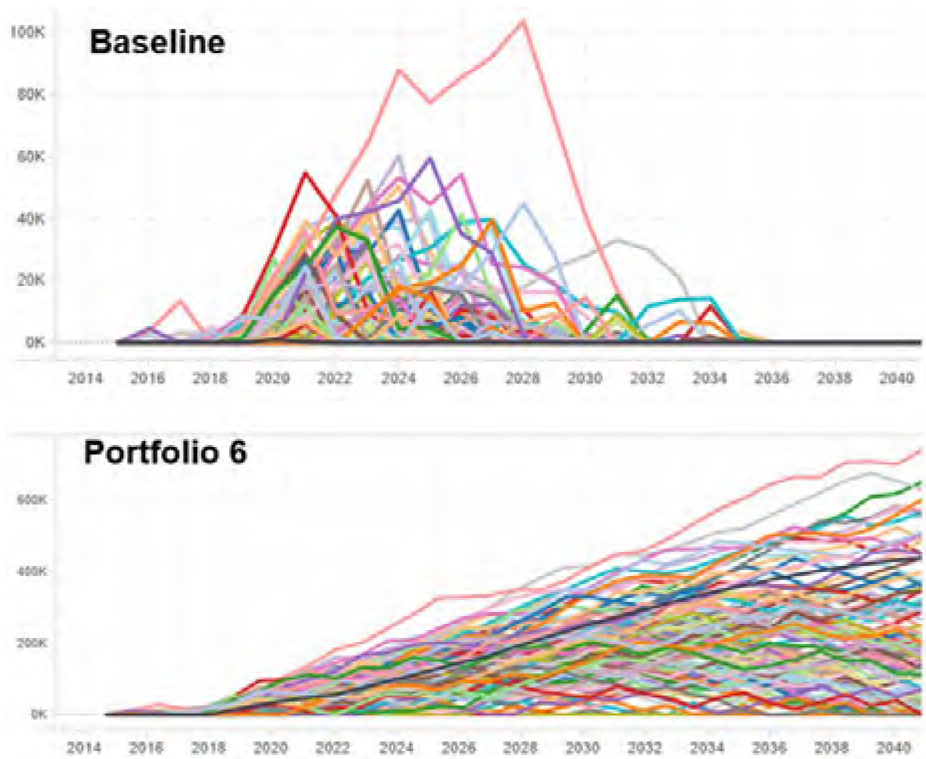


Figure 4-19: Unmet Demands of Portfolio 7 Compared to Baseline

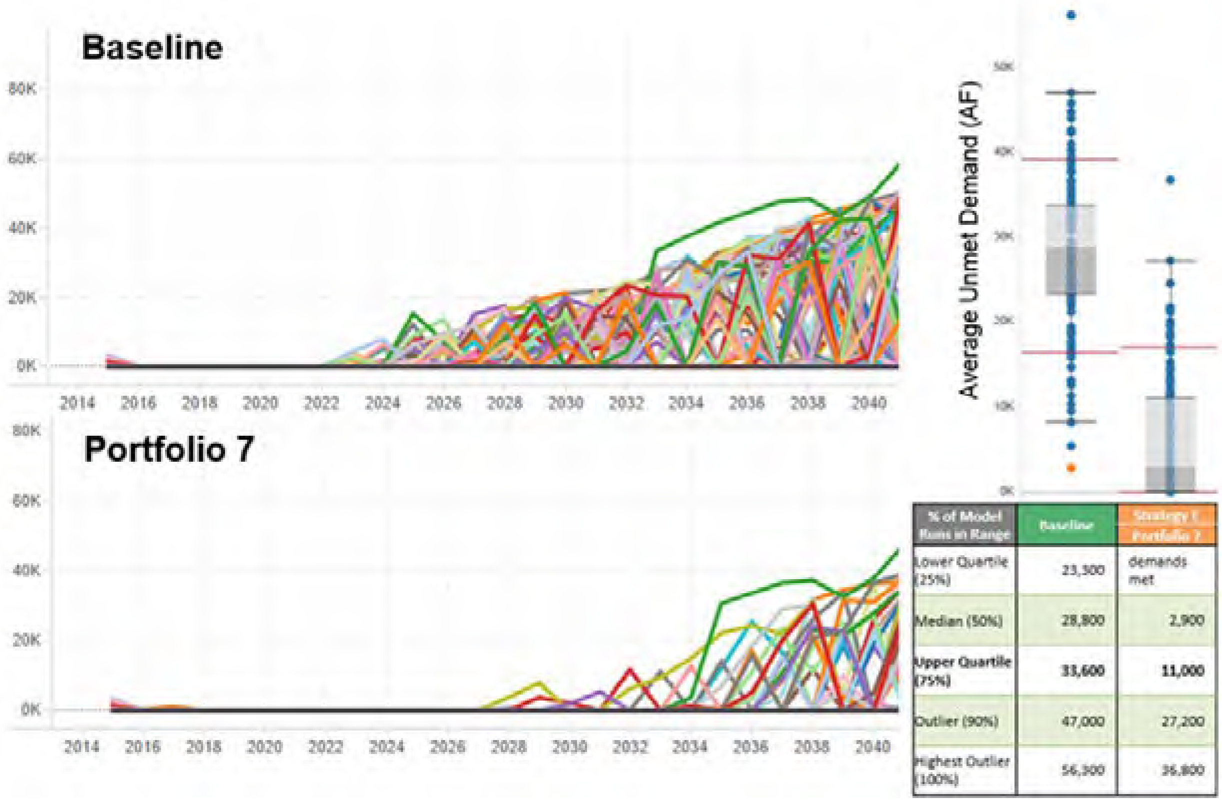
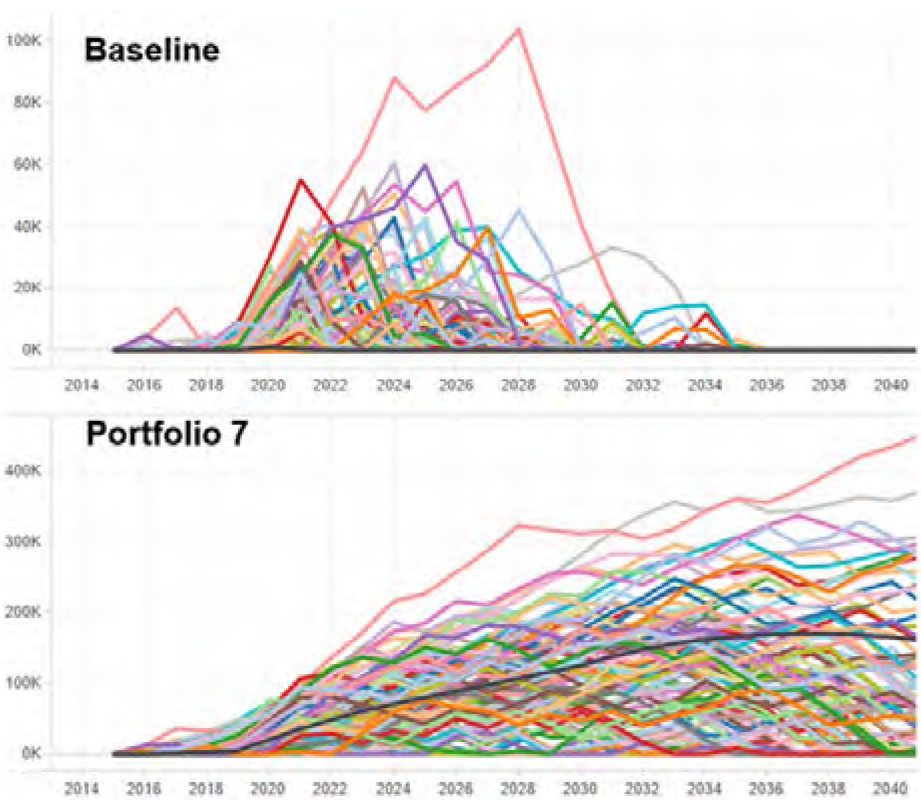


% of Model Runs in Range	Baseline	Strategy [illegible] Portfolio 7
Lower Quartile (25%)	23,300	demands met
Median (50%)	28,800	2,900
Upper Quartile (75%)	33,600	11,000
Outlier (90%)	47,000	27,200
Highest Outlier (100%)	56,300	36,800

Figure 4-20: Stored Groundwater Balance of Portfolio 7



whether stored water continues to build or drawn down through 2040.

Unmet demands for Portfolio 8 in comparison to the baseline model run are shown in Figure 4-21. Portfolio 8 meets projected demands through 2040 100% of the time.

Stored water balances are illustrated in Figure 4-22. As shown, groundwater balances begin to accumulate in Portfolio 8 by 2020 with majority of model runs continuing to build stored water through 2040. Due to variability in wet year supplemental supplies, stored water balances become highly variable and unclear whether stored water continues to build or drawn down through 2040.

In summary, Portfolio 7 and 8:

- Portfolio 7 has a supply shortfall of up to 11,000 AFY under 75% of the climate scenarios
- Portfolio 8 meets demand under 100% of the climate scenarios, this increase in performance is due to the addition of recycled water.
- Both portfolios have the potential to build stored groundwater through 2040, but the amount in storage varies by climate conditions
- After 2030, Portfolio 8 builds stored groundwater under majority of climate scenarios due to the addition of recycled water.

Table 4-5: Supply Totals for Portfolio 7 & 8

5. Conclusions & Next Steps

Core Findings of the 2015 IRP

Lessons Learned from the Climate Simulations

Final IRP Recommendations and Next Steps

Strawberry fields near a new development in Ontario.

Conclusions & Next Steps

With the adoption of the Chino Basin OBMP in 2000, the region embarked on a new era of water management. Over the past 15 years, more than $500 million was invested in the development of local water supplies. This resulted in the expansion of the regional recycled water program as well as in the development of significant groundwater capture, treatment, and storage programs.

As a result, when the record-breaking drought of 2012 began, the region was prepared. The region has had sufficient water supplies available to meet water needs during the drought of the last 4 years without constraining new development or economic growth. These local water resource programs form the foundation for the region's future water resiliency.

Climate change is now creating uncertain conditions and new water management challenges for the region's future. The purpose of the 2015 IRP is to evaluate the resiliency of the region's water resources under climate change and to identify the best strategies for ensuring that the region's future water needs through 2040 can be sustainably met. With the information from the IRP, the region has a roadmap to guide the next 25 years of regional investments in water supply development and management programs.

CORE FINDINGS

The region adopted goals for the 2015 IRP. In looking to the future, the region wanted a water development and management plan that would accomplish the following:

Resilience — Regional water management flexibility to adapt to climate change, economic growth, and any changes that limit, reduce, or make water supplies unavailable.

Water Efficiency — Meet or exceed rules and regulations for reasonable water use.

Sustainability — Provide environmental benefits, including energy efficiency, reduced green house gas emissions, and water quality improvements to meet the needs of the present without compromising the ability of future generations to meet their own needs.

Cost Effectiveness — Supply regional water in a cost-effective manner and maximize outside funding.

To achieve these goals, the IRP evaluated projected water needs and available water supplies through 2040. Future climate change scenarios were then used to "stress-test" an array of water development actions that were organized into "portfolios".

These results form the basis for the IRP's final recommendations. The core findings are:

1. The region's past investments in local water supplies and the diversification of the available water resources have positioned the region well to deal with the future impacts of climate change. If no further actions were taken beyond the currently planned investments in regional supplies and water use efficiency, the region would be able to meet 80-

90% of its projected water needs by 2040 .

2. Portfolios that combined water supply and water efficiency actions yielded the most adaptive strategies for the region. Many portfolios were able to reduce the region's risk of not having sufficient water supplies to meet future needs. Several portfolios were able to dramatically increase the amount of water stored in the Chino Basin. The portfolios that performed the best under the climate change scenarios were:

   - 2B – Maximize recycled water (includes bringing in external recycled water supplies), implement modest water use efficiency, and access supplemental imported water
   - 3A – Maximize recycled water (includes bringing in external recycled water supplies) and implement moderate water use efficiency
   - 3B – Maximize recycled water (includes bringing in external recycled water supplies) and implement high water use efficiency
   - 4 – Maximize supplemental water supplies and recycled water (includes bringing in external recycled water supplies)
   - 5B – Maximize the purchase of MWD water supplies, use of recycled water (includes bringing in external recycled water), and implementation of modest water use efficiency

LESSONS LEARNED FROM THE CLIMATE SIMULATIONS

Value of Water Use Efficiency — The climate scenarios reveal that the addition of very modest levels of water use efficiency (such as 10% reduction in water use) improved the performance of all portfolios and yielded significant benefits the region. The regional benefit is demonstrated through Portfolio 3B in which the actions of two Agencies achieving the State's existing water use efficiency standards results in the region's capacity to increase supplies in groundwater storage while meeting water needs through 2040.

Value of Recycled Water — The climate scenarios confirmed that recycled water is the region's most climate resilient water supply because the amount of available water to the region is not impacted by dry years. The regional benefit of maximizing recycled water is demonstrated through the comparison of Strategy B and C in which the use of recycled water enables the region to increase supplies in groundwater storage, especially in combination with increased water use efficiency.

Value of Supplemental Water — The climate scenarios highlight the importance of securing supplemental water – surface, imported, and external recycled water supplies – when it is available to build a stronger supply buffer for dry years or when State Water Project availability is limited. The regional benefit of opportunistically securing these external water supplies is demonstrated through the comparison of Portfolios 4, 5, and 6 which enables the region to increase supplies in groundwater storage, especially in combination with increased water use efficiency.

Value of Increasing Groundwater Storage — The climate scenarios affirmed the importance of adequate groundwater reserves in addressing future climate uncertainties or catastrophic events, such as a major facility or pipeline break or a loss in supplies. A broader regional benefit is the role that these reserves can play when managed as a regional water bank to enhance water supply reliability within the Santa Ana Watershed and across Southern California. Portfolios 4, 5, 6 and 8 highlight the value to the region of the increased flexibility and resiliency resulting from increased groundwater storage.

RECOMMENDATIONS & NEXT STEPS

Plans to protect air and water, wilderness and wildlife are in fact plans to protect man.

-Stewart Udall

The region adopted the following core recommendations for the 2015 IRP:

- **Continue investment in recycled water** projects to maximize the beneficial reuse.
- **Acquire low TDS supplemental water to enhance groundwater quality** to sustain production and reduce salinity.
- **Implement water use efficiency measures** to reduce current urban demand by at least 10% to enhance water supply resiliency.
- **Strategically maximize the purchase of supplemental water** for recharge or in-lieu when available.
- **Include external supplies**, consisting of exchanges, storage, and water transfers, **strategically in combination with conservation** to augment groundwater recharge, recycled water, **and build storage reserves**. External supplies include surface, imported, and non-potable water.
- **Continue to maximize stormwater recharge projects**, including rainwater capture and infiltration.

These recommendations will be evaluated through a Programmatic Environmental Impact Report in mid-2016. As funding opportunities become available, specific project cost and environmental assessments will be conducted as needed, particularly in relation to the regional benefit of the proposed actions. Phase 2 of the IRP will address additional detailed project level analysis including project scopes, costs, prioritization, and implementation schedule.

Table 5-1: Summary of How Phase 1 Recommendations Meet the IRP Goals

Water Use Efficiency	
Water Efficiency	This would help meet rules and regulations for reasonable water use now and in the future.
Sustainability	Savings realized through the implementation of the program extends the groundwater production for future generations.
Resilience	When combined with other programs, such as recycled water, creates storage to accommodate for abnormal and catastrophic events.

Recycled Water	
Water Efficiency	This would help meet rules and regulations for reasonable water use now and in the future, especially meeting current state mandates.
Sustainability	As a climate resistant supply, the beneficial use of recycled water when combined with Water Use Efficiency builds reserves within the Chino Basin.
Resilience	When combined with other programs, such as Water Use Efficiency, creates storage to accommodate for abnormal and catastrophic events.

Supplemental Water	
Water Efficiency	This would help meet rules and regulations for reasonable water use now and in the future, especially meeting current state mandates.
Sustainability	This would help meet rules and regulations for reasona-ble water use now and in the future, especially meeting current state mandates.
Resilience	as a climate resistant supply, the beneficial use of recycled water when combined with Water Use Efficiency builds reserves within the Chino Basin.

Groundwater Storage	
Sustainability	Storage reserves reduce dependence on climate variable supplies and are not impacted by climate once the supplies are in storage. As a climate resistant supply, the reserves can be used responsibly by future generations without depleting the Chino Basin.
Resilience	When combined with other programs, such as Water Use Efficiency, Recycled Water and Supplemental Water, creates storage to accommodate for abnormal and catastrophic events.

Table of Contents

Abbreviations List

AWE – Alliance for Water Efficiency
CDR – Center for Demographic Research
CII – Commercial-Industrial-Institutional
CVWD – Cucamonga Valley Water District
FIRE – Financial Activity & Real Estate
FWC – Fontana Water Company
GIS – Geographic Information Systems
IEUA – Inland Empire Utilities Agency
IRP – Integrated Resource Plane
MVWD – Monte Vista Water District
MWD – Metropolitan Water District of Southern California
NAICS – North American Industry Classification Systems
RMC – Raines Melton and Carella
RTP - Regional Transportation Plan
SCAG – Southern California Association of Governments
SCS – Sustainable Communities Strategy
SIC – Standard Industrial Classification
TAZ – Traffic Analysis Zone

Introduction

This user guide documents the structure and use of the IEUA Long Term Demand Forecast Model.

Objectives

The model was constructed with the following objectives:

- Forecast demand and demand variability to 2040 in support of the IRP development process.
- Forecast demand as consumption, which we define as all of the consumption within IEUA service area boundaries.
- Base the demand forecast on the latest demographic forecast.
- Utilize a demand forecast method consistent with the MWD demand forecast methods.
- Utilize a conservation forecast method consistent with the AWE Tracking Tool that IEUA currently uses for conservation planning.
- Provide a way to assess the variability of future water demand forecasts to a wide range of scenarios that are built with a range of best-available data sources to accurately depict the effect of future uncertainties.

Approach

The approach in model development can be characterized as:

1. Acquiring the latest demographic forecast data from the SCAG 2012 RTP for all of the area within IEUA, for its retail water service areas, for its cities, and for its waste water tributary areas. (Enacted by the Center for Demographic Research.)
2. Inputting the demographic forecast into the demand forecast econometric equations to create a base forecast.
3. Calibrating the base forecast to normal demand (weather-normalized, employment-normalized). A separate statistical model of historical IEUA monthly water demand was estimated to develop empirical relationships between weather variation, the business cycle, and IEUA demand variability.
4. Inputting the quantified active and passive conservation forecast from the latest version of the AWE Tracking Tool that IEUA uses for conservation planning.

Discussion

Econometric Equations. MWD has cooperated with IEUA in the development of the demand forecast methods. Appendix A provides a review of the analytic structure of their long term water demand models.

Demand as Consumption. The base forecast has been calibrated to normalize demand –that is demand conditional on normal weather and normal economic activity. Note the caveat that some pumpers who are not accounted for by retailers may not be included.

Demographics 2035 to 2040. The SCAG 2012 RTP demographics only go out to the year 2035. We utilize a trend method similar to MWD for the years 2035 to 2040.

Section A: Index

The sections of this document correspond to the worksheets in the Long Term Demand Forecast Model. The following table provides the view of the first worksheet "Index". Clicking on any hyperlink will navigate to that section of the spreadsheet.

A MUNICIPAL WATER DISTRICT

IEUA Long Term Demand Forecast Model

Index of Worksheets	
Sheet Name	**Description**
Index	Index of worksheets for navigation
ControlPanel	Make scenario choices and see results.
Chart_Data	Arrays of data for charts
Model_Base	Base Case Scenario
Model_Scenario1	Scenario 1
Model_Scenario2	Scenario 2
Model_Scenario3	Scenario 3
WBBRS_Implementation	Inputs for water budget
WUE_Inputs	Inputs for water use efficiency plans

Section B: Control Panel

The *Control Panel* worksheet contains the "Scenario Manager" that allows the user to explore up to three different scenarios that use different combinations of future demand drivers. Demand drivers can include both short term drivers—such as one year weather swings--and long term drivers of future water demand such as population or employment growth. Water Use Efficiency drivers are broken out separately and include Water Budget Based Rate Structures and more traditional WUE/conservation programs. For more information on statistical analysis of Short Term IEUA Demand refer to Appendix E.

Each demand driver is discussed in sequence.

	Scenario Manager
Item	
	Scenario Name
Short Term Drivers	Drought Persistence
	Economic Cycle
	Short-Term Weather
Long Term Drivers	Sustainable Communities Housing
	Dwelling Units per Land Area
	Median Household Income Growth
	Long Term Climate Change
WUE Drivers	Water Budget Based Rate Structure (WBBRS)
	WUE Level

Short Term Drivers – 5 Years – 2015 to 2020

- **Drought Persistence** defines how much of recent demand reductions will persist into the future
    - amount of recent reduction that is permanent
        - 0 percent implies that everything will return to the baseline forecast
        - 4.6% percent implies that the 4.6% recent reduction is a permanent lifestyle change

The unexpressed bugbear is what is the "recent reduction"? It is reasonable to assume that one would want to know how much of a raw change in consumption is due to recession or weather. Fortunately IEUA has an empirical basis for such a determination in the short term IEUA demand model that is the source of the 4.6% recent reduction in demand (not attributable to recessionary effects.)

- **Economic Cycle** –The user can specify how much recession or boom could bump demand in a single year using the estimated annual standard deviation of business cycle effects from the short term IEUA demand model.
    - Recession year – demand minus 1 standard deviation from the IEUA short run water demand forecasting model
    - Baseline year—normal business cycle, no change
    - Growth year – demand plus 1 standard deviation from the IEUA short run water demand forecasting model

- **Short Term Weather –** Single wet, single dry, three consecutive dry years (required by UWMP). The effect of weather variation is defined using the estimated annual standard deviation of weather effects from the short term IEUA demand model.
    - Single wet year – demand minus 1 standard deviation from the IEUA short run water demand forecasting model
    - Single dry year – demand plus 1 standard deviation from the IEUA short run water demand forecasting model
    - Multiple dry year – demand plus 1.6 standard deviations from the IEUA short run water demand forecasting model

Long Term Drivers—2021 - 2050

- **Sustainable Communities Housing –** Derived scenarios explored in the SCAG Sustainable Communities Strategy, 2012 Regional Transportation Plan (p.114).
    - Baseline—future residential growth resembles the past, of which approximately 40% was high density multiple family.
    - More Sustainable—future residential growth resembles is approximately 71% high density multiple family.
    - Max Sustainable—future residential growth resembles is approximately 71% high density multiple family.

- **Dwelling Units per Land Area –**This driver allows another method of exploring effects of potential future densification.
    - Low Growth—future dwelling units per land area becomes less dense (minus one percent per year)
    - Baseline—future residential growth resembles past dwelling units per land area.
    - High Growth—future dwelling units per land area becomes more dense (plus one percent per year)
    - Very High Growth—future dwelling units per land area becomes more dense (plus two percent per year)

- **Median Household Income Growth –**3 alternative assumptions: low, baseline (2012 RTP), and high
    - Low Growth—median household income grows lower (minus one percent per year)
    - Baseline— median household income grows lower at predicted rate
    - High Growth— median household income grows faster than the baseline (plus one percent per year)

- **Long Term Climate Change –** Long term climate change is modeled by using recent GCC model predictions of potential increases in temperature with the short term IEUA demand model estimated temperature elasticity to depict this effect. (http://scenarios.globalchange.gov/report/regional-climate-trends-and-scenarios-us-national-climate-assessment-part-5-climate-southwest)
    - No Change— no long term climate change
    - P50 Median Expected Climate Change— 3.2% by 2040
    - P80 Median Expected Climate Change— 4.3% by 2040

WUE Drivers

- **Water Budget Based Rate Structure (WBBRS)** are depicted with alterative assumptions of how many agencies will adopt and roll out WBBRS over the next 5 years. These will be modeled as separate activities within the AWE Water Conservation Tracking Tool.
  - Low_Rollout_1 Agency—This results in approximately 10% of Single Family and Irrigation customers being affected within 5 years.
  - Mid_Rollout_2 Agencies--This results in approximately 30% of Single Family and Irrigation customers being affected.
  - High_Rollout_All Agencies-- This results in all Single Family and Irrigation customers being affected.

Note that the Baseline IEUA Demand Model allows a "pure price" effect—how customers would respond to an increase in the real average price of water

- **WUE Level –** the level of WUE Programs being implemented derives from separate account in the AWE Water Conservation Tracking Tool

  - Programmatic (Device-driven) WUE Programs -- Tiers 1, 2, 3 developed as part of the WUE Business Plan.

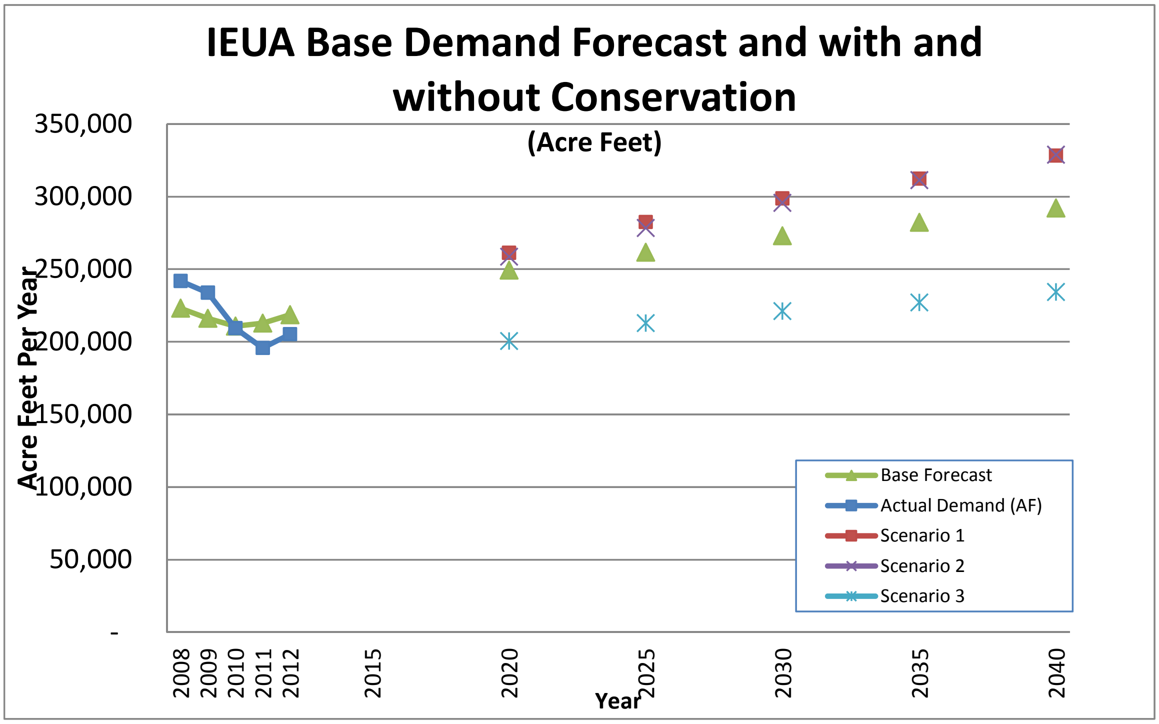
The Control Panel Worksheet contains drop down boxes to select values of demand drivers. A Collection of assumptions on demand drivers constitutes a demand forecasting scenario. Three scenarios are allowed. By allowing the user to define and control sources of forecast uncertainty in this control panel, one can more quickly develop a feel for which sources of uncertainty matter more than others using the visual feedback of dynamically changing plots of future water demand forecasts.

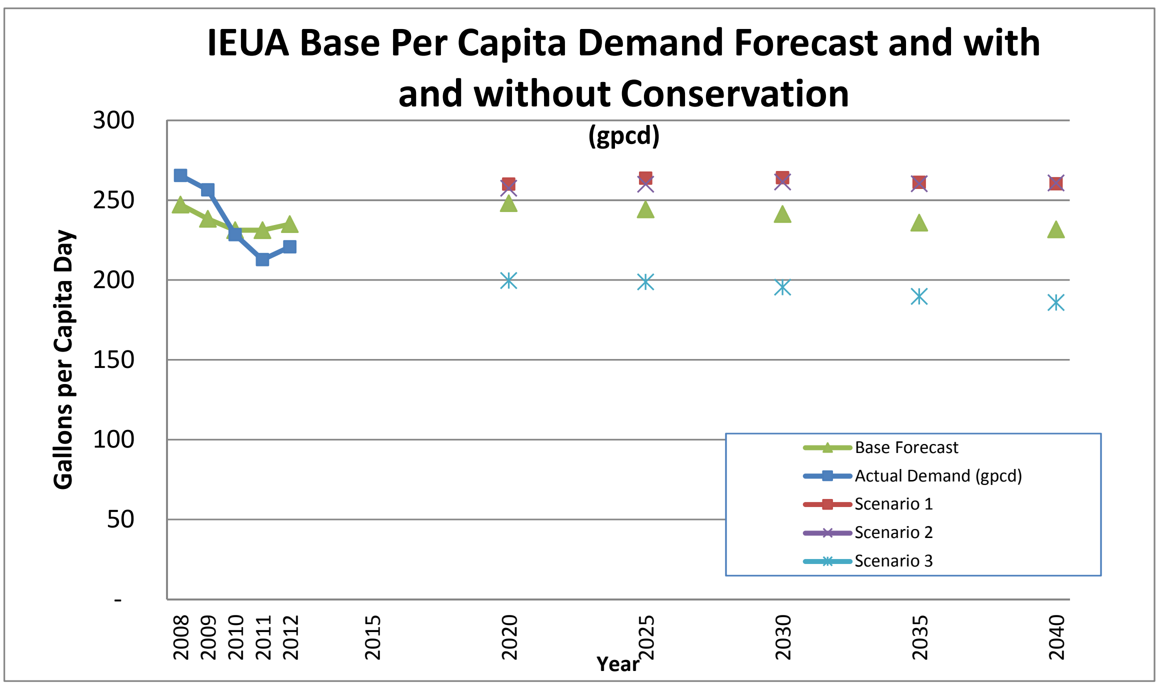
Each green box contains drop down boxes to choose values for each demand driver.

Scenario Manager Use drop down box to enter values. Do not copy and paste unless you paste values only.

Item		Scenario 1:	Scenario 2:	Scenario 3:
	Scenario Name	High	Intermediate	Low
Short Term	Drought Persistence	Drought_4.6%Permanent	Baseline	Drought_4.6%Permanent
Drivers	Economic Cycle	Growth Year	Baseline	Recession Year
	Short-Term Weather	Multi-Yr Dry	1-Yr Dry	1-Yr Wet
Long Term	Sustainable Communities Housing	Baseline (40% MF)	More Sustainable (71% MF)	Max Sustainable (96% MF)
Long Term	Dwelling Units per Land Area	Baseline	Baseline	Baseline
Drivers	Median Household Income Growth	Baseline	High Growth	Low Growth
	Long Term Climate Change	Change 4.3%_P80	Change 3.2%_P50	No Change
WUE	Water Budget Based Rate Structure (WBBRS)	None	Low_Rollout_10pctSF/Irr	High_Rollout_100All
Drivers	WUE Level	Level 3	Level 2	Level 3

The results can be readily observed in the forecast chart below the control panel.





Section C: Chart Data

This worksheet collects and arranges data needed to create charts on the Control Panel worksheet.

Section D: Model Base

The Model_Base worksheet contains the following:

- Base Model Parameters
  - Single Family
  - Multi-Family
  - Revised Non-Residential Models
  - Price effect
- Base Model Input - Region Dependent
- Base Model Output - Demand Forecast with Price-effect
- Demand Forecast Model

Base Model Parameters

The Base Model Parameters table contains the econometric parameter estimates that drive the base model forecast. The Base Model Parameters are revised only for major updates and revisions to the model. For everyday policy scenario runs, the Base Model Parameters are left alone, generally, except for possible sensitivity testing. The lag variables refer to statistical effect at different periods of time. For example, Lag 1 indicates the effect that weather in one year has on the subsequent year. The Base Model Parameters table starts in Row 5 of the Model_Base worksheet, and the values are reproduced in Appendix D:

Single Family Model. The single family model was estimated as a function of the following:

1. Weather variables that include the amount of rain, rainy days, and temperature— all of which also included lag variables of one period. Rain and temperature included additional lag 2 variables in the model.
2. Socioeconomic variables include marginal price, income, density (housing units per acre), and people (persons per household).
3. Conservation variables include one that indicates mandatory conservation, and another that indicates voluntary conservation.
4. Drought indicates drought during the period.
5. Month variables are used to estimate the effect of month on seasonal demand.

MODEL PARAMETERS								
Single Family Model								
	WEATHER	LAG 0	LAG 1	LAG 2				
	Rain	-0.0482	-0.0589	-0.0192				
	Rainy Days	-0.0088	-0.0047					
	Temperature	0.4647	0.3482	0.2942				
	SOCIOECONOMIC							
	Marginal Price	-0.1947						
	Income	0.2722		MONTH				
	Density	-0.6154		January	0.0233		July	0.5785
	People	0.5485		February			August	0.5603
				March	0.0659		September	0.4775
	CONSERVATION			April	0.2166		October	0.3361
	Voluntary	-0.0258		May	0.3799		November	0.1993
	Mandatory	-0.1033		June	0.5128		December	0.1056
	DROUGHT							
		-0.0503						

Multi-Family Model:

1. Weather variables include the amount of rain and temperature. Rain includes a variable with no lag, and also variables with 1 and 2 lag periods. Temperature includes one variable with 1 lag period.
2. Socioeconomic variables included are the same set as for the single family model.
3. Conservation variables include one that indicates mandatory conservation, and another that indicates voluntary conservation.
4. Month variables included are the same set as for the single family model.

Multi-Family Model						
WEATHER	LAG 0	LAG 1	LAG 2	LAG 3		
Rain	-0.0343	-0.0205	-0.0069			
Temperature		0.1375				
SOCIOECONOMIC						
Marginal Price	-0.1626		**MONTH**			
Income	0.3102		January	0.037	July	0.2255
Density	-0.5262		February		August	0.2353
People	0.4496		March	0.0009	September	0.1997
			April	0.0715	October	0.1414
CONSERVATION			May	0.1405	November	0.1037
Voluntary	-0.0452		June	0.1951	December	0.0858
Mandatory	-0.1162					

Revised Non-Residential Model:

1. Weather variables include the amount of rain and cooling degree days, both with no lag, one period lag, and two periods lag.
2. Socioeconomic variables include one for the marginal price of water.
3. Conservation variables include one that indicates mandatory conservation, and another that indicates voluntary conservation.
4. Month variables included are the same set as for the single family model.
5. Employment variables included are Manufacture and Services as it is consistent with current MWD implementation. The model has the structure to accept, in addition, variables for Construction, Transportation, Wholesale, Retail, Finance, and Government employment.

Revised Non-Residential Model							
	WEATHER	LAG 0	LAG 1	LAG 2			
	Rain	-0.05817	-0.04906	-0.01905			
	Cooling degree Days	0.01037	0.01171	0.01200

	Mandatory	-0.13011		May	0.2980	November	0.1438
				June	0.3623	December	0.0658
EMPLOYMENT COEFFICIENTS							
Construction	Manufacture	Transportation	Wholesale	Retail	Finance	Services	Government
0.0000	**0.80297**	0.0000	0.0000	0.0000	0.0000	**0.55242**	0.0000

Price Effect

The price effect parameters reduce the effect of price on demand to account for increasing levels of conservation over time. Customers may have fewer opportunities to conserve if they already have conservation devices and behaviors.

The Constant Price parameter (Cell J79) toggles on and off the use of constant 1990 prices. When prices are constant, there are no price impacts on demand. This parameter could be used for sensitivity testing.

Price Effect						
The price effect is reduced to	**Year**	**Price Effect**		**Year**	**Price Effect**	
account for the effects of price	2008	56%		2025	33%	
captured in the End-Use module.	2009	54%		2030	33%	
	2010	52%		2035	33%	
The original MWD model had one	2011	50%		2040	33%	
price effect across the forecast.	2012	48%		2045	33%	
This updated model allows for the	2015	42%		2050	33%	
effect to be reduced in phases, as	2020	33%				
End-Use conservation increases.						
Constant Price (effects of 1990 price across all years) Toggle: 1 = use current rate, 0 use 1990 rates						1

Base Model Input

The Base Model Input tables start in Row 82 of the Model_Base worksheet. These tables contain the demographic input data and the equations to create the demand forecast. The Base Forecast is the forecast under the assumption of no new conservation savings.

Demographic Inputs

The latest demographic forecast for IEUA was acquired from the SCAG 2012 RTP data base. The Center for Demographic Research (CDR) at California State University, Fullerton utilized geographic information system (GIS) methods to extract data only for the area within IEUA service area boundaries. Detailed analysis of boundaries was conducted to assure that households, population, and employment were properly allocated. Appendix B contains detailed description of the GIS methods used to generate the demographic data set. Appendix D contains demographic input tables. The complete set of demographic inputs is as follows:

1. Population (Total Population, SCAG 2012 RTP data from CDR)
2. Occupied Housing Units (Households, SCAG 2012 RTP data from CDR)
3. Household size (Persons per Household, MWD)
4. Housing Density (Units per Acre, MWD)
5. Median Household Income (MWD)
6. Urban Employment by Sector (SCAG 2012 RTP data from CDR)
7. Marginal Water Price (MWD)

Demographics 2035 to 2040. The SCAG 2012 RTP demographics only go out to the year 2035. We utilize a trend method similar to MWD for the years 2035 to 2040, by applying the compounded average growth rate from 2008 to 2035.

The MWD employment categories are by grouped SIC codes and the SCAG 2012 RTP are grouped by NAICS codes. The following cross walk—developed by consulting SIC and NAICS definitions—was used to group SCAG NAICS into MWD SIC categories.

MWD (SIC)	SCAG (NAICS)
Construction	CONST
Manufacturing	MANU, AG
Utilities	TRANS, .5*INFO
Trade	WHOLE
Retail Trade	RET
Real Estate	FIRE
Service	PROF, EDU, ARTENT, OTHER, .5*INFO
Government	PUBADM

Source: Demographics_Compare_1.xlsx

Employment Productivity Factors by Year

1. Construction (MWD)
2. Manufacturing (MWD)
3. Transportation & Utility's Comm (MWD)
4. Wholesale Trade (MWD)
5. Retail Trade (MWD)
6. Finance, Insurance, and Real Estate (MWD)
7. Service (MWD)
8. Government (MWD)

Drought Restrictions

The table of drought restrictions contains the set of indicator variables that can be used to create forecast scenarios with conditions of drought and conservation restrictions.

1. Residential (Voluntary/Mandatory)
    a. Single Family
    b. Multi-Family
2. Employment (Voluntary/Mandatory)
3. Hot & Dry

Model Intercept and Calibration Inputs

The table labeled Model Intercept and Calibration Inputs contains the parameters to adjust the demand forecast to calibrate to the best estimate of normal weather demand. The table contains adjustments for the single family, multi family, and non-residential sectors. In addition the table below labeled Percentage Other can be used to adjust the other demand sector.

Model Intercept and Calibration Inputs

Model Intercept Adjustments

	Adjusted	Model Interc
Single-Family	5.10	4.83
Multi-Family	5.31	5.66
Non-Residential	0.86	0.94
		medi
Model Calibration	0.96	
SF Site Adjustment	0.5065	
MF Site Adjustment	-0.1143	
NR Site Adjustment	-0.0441	

All of the values in the table are sourced from MWD with the exception of Model Calibration. Since we are calibrating for one agency, we set the Model Calibration parameter by minimizing the difference between the modeled demand and normal demand.

Normal demand was estimated by methods described in the technical memo "Statistical Analysis of Short Term IEUA Demand: Empirical Estimates of Demand Trends." This memo documents the weather-normalization and employment-normalization of time series data provided by IEUA. Water demand was approximated as the sum of delivered supplies. The advantage of using this data source is that the modeling effort was based on consistent system-wide monthly data. And in addition, the monthly water production could be adjusted for changes in storage. Although these models may be described as "demand" models, the data on which the models are estimates would be better described as "supply" measures. To the extent that storage issues are accounted for, the difference between these two constructs should be made small.

We have also provided a second calibration that isolates differences between IEUA and MWD methods. The second calibration option takes actual demand history provided by MWD and then applies the weather and employment effects from our statistical analysis to yield normal demand based on MWD data. The model provides a toggle to switch between the two calibration methods for comparison purposes (Cell G161).

Minimize Delta to 2012 Normalized Demand by Adjusting Model Calibration in Cell E138

Source of Actual Demand	Normal Effects Estimation	2012 Demand	Delta	Model Calibration	Toggle 1=IEUA
IEUA	A&N	218,614	(0)	0.956	1
MWD	A&N	243,922	25,308	0.983	

To run the calibration, run a Goal Seek in Excel that sets delta in Cell E161 (or E162) to zero by changing Cell E138. (In Excel, click on Data, What If, and then Goal Seek). This method calibrates the model to normal demand in the most recent year from the statistical analysis (2012).

Adjusted Normal Weather by Month

These values are from MWD and are calculated from tables labeled Actual Climate Data, which contain Median Rainfall, Median Rain Days, Normal Temperature, and Normal Cooling Degree Days.

Base Model Output

The Base Model Output table (Row 171) is the base forecast that includes the price effect, but it does not include new conservation savings. The following is an example of the Base Model Output table for single family multi-family and total acre feet demand (Non-Residential and Other are not shown separately, but they are included in Total demand).

ACRE-FEET									
	Municipal and Industrial Water Demand - Base Forecast with Price Effect (Acre-Feet)								
				by Sector					
		TOTAL		Single-Family			Multi-Family		
YEAR	Annual	Summer	Winter	Annual	Summer	Winter	Annual	Summer	Winter
2008	223,185	147,008	76,177	103,644	69,914	33,730	25,879	15,963	9,916
2009	216,118	142,398	73,720	103,031	69,501	33,531	25,815	15,924	9,891
2010	210,826	138,957	71,869	103,262	69,656	33,606	25,979	16,025	9,954
2011	212,918	140,330	72,588	103,706	69,956	33,750	25,967	16,018	9,949
2012	218,614	144,088	74,526	106,581	71,895	34,686	26,645	16,436	10,209
2015	232,443	153,406	79,037	113,054	76,315	36,740	27,994	17,268	10,726
2020	249,390	164,505	84,885	120,523	81,356	39,167	31,667	19,533	12,133
2025	263,113	173,501	89,613	126,358	85,295	41,063	34,301	21,158	13,143

Demand Forecast Model

The Demand Forecast Model tables (starting in Row 225) contain the demand forecast equations for each forecast period.

Conservation Inputs

The Conservation Inputs tables (starting in Row 696) contain output from the AWE Tracking Tool that IEUA uses to plan conservation activities.

- Plumbing Code Savings by sector
- Historically Achieved (Retrospective) Active Savings by sector for peak and off-peak sectors

The demand forecast calls for Summer and Winter demand, so we apply the peak and off-peak conservation estimates from the AWE Tracking tool to Summer and Winter respectively.

The demand forecast also calls for the following sectors: Single Family, Multi Family, Non Residential, and Other. The AWE Tracking Tool has Commercial, Industrial, and Institutional separately categorized as well as an Irrigation category. We summed these into the Non-Residential sector on the Conservation_Inputs Worksheet.

Note that refined adjustments to the conservation forecast are possible in the AWE Tracking Tool that accompanies the demand forecast model. For example, past and future conservation activities can be added or updated. Past active conservation is entered on the Model_Base worksheet. The Base

Scenario on the Model_Base worksheet assumes there is not additional future active conservation. Scenarios 1 – 3 each have different plans for future active conservation that are linked to the active conservation input worksheets on Model_Scenario1, Model_Scenario2, and Model_Scenario3 respectively.

Note also that the Conservation_Inputs Worksheet takes the results from the AWE Tracking Tool and calculates the future addition to active and passive conservation beyond what is embedded in 2012. That is the latest year of the statistical normalization analysis based on actual demand (which by definition embodies all past active and passive conservation to date). The calculations for the future additions to active conservation accounts for the fact that active conservation has a defined savings life. Unless the conservation activity is replicated in the AWE Tracking Tool, the conservation effect will expire and result in an increment rather than a decrement to future demand. As a default conditions, the model assumes that future active conservation will be maintained at the same level as the present active savings level. This is a place holder until IEUA has developed the next phase of their conservation planning.

Conservation Forecast

The Conservation Forecast tables (Row 832) contains a forecast that is constructed by starting with the Base Forecast and subtracting out the added passive and active conservation forecast moving forward.

Note that since we have calibrated to a current estimate of normal demand, we subtract out only added future conservation above and beyond what is already embedded in the current estimates. The advantage of this approach is that it allows us to anchor the demand forecast to the best estimate of current measured demand data.

Cities Forecast

The Cities Forecast (Row 937) was created by disaggregating the IEUA forecast using the following method:

- Single Family was disaggregated by the share of single family housing units in the city
- Multi Family was disaggregated by the share of multi-family housing units in the city
- Non Residential was disaggregated by the share of employment in the city
- Other was disaggregated by the share of population in the city

When comparing a disaggregate forecast of base demand at a City level to recent realized water demand, analysts will need to recognize that realized demand does not reflect, in general, normal weather and normal business cycle conditions. When comparing alternative forecasts, analysts should begin by comparing the demand driver measures of population, housing stock, and employment.

Retail Service Areas Forecast

The Retail Service Areas Forecast (Row 1219) was created by disaggregating the IEUA forecast using the following method:

- Single Family was disaggregated by the share of single family housing units in the retail water service area

- Multi Family was disaggregated by the share of multi-family housing units in the retail water service area
- Non Residential was disaggregated by the share of employment in the retail water service area
- Other was disaggregated by the share of population in the retail water service area

When comparing a disaggregate forecast of base demand at a Retail Service Area level to recent realized water demand, analysts will need to recognize that realized demand does not reflect, in general, normal weather and normal business cycle conditions. When comparing alternative forecasts, analysts should begin by comparing the demand driver measures of population, housing stock, and employment.

Indoor/Outdoor Forecast

The Indoor/Outdoor Forecast tables break down total forecasted demand into indoor and outdoor components (Row 1560).

Please refer to Appendix C for documentation on the estimate of Indoor/Outdoor end uses in the IEUA service area.

Two methods were examined to estimate outdoor use across customer classes (See Appendix C). The minimum month method is common practice, yet it ignores outdoor use in climates where there is winter irrigation. The seasonal variation method applies the seasonal variation from dedicated irrigation meters to mixed meter customer classes. This method definitively establishes that the assumption of zero winter irrigation is untenable. The recommended seasonal variation method estimates that 62 percent of total water demand in the IEUA service area is outdoor water use. The model can provide additional estimates of how indoor and outdoor end uses are divided seasonally:

Summer (April to Oct.)		Winter (Nov. to March)	
Indoor	Outdoor	Indoor	Outdoor
33%	67%	49%	51%

Note that this split occurs in the model after the Base and Conservation Forecasts, and thus proportions of indoor and outdoor added active conservation savings will not be reflected. However, for the indoor outdoor analysis of passive conservation savings we performed to assist wastewater design team, we disaggregated passive conservation coming out of the AWE Tracking Tool into indoor and outdoor components. In addition, we disaggregated passive conservation into components derived from new construction and components derived from existing sites.

Section E: Model Scenarios (1-3)

There are three Model_Scenario worksheets that contain each of three scenarios controlled by the Control Panel. Each of these worksheets is based structurally on the Base_Model worksheet with differences in either data sources or assumptions that comprise the defined scenarios.

Section F: WBBRS Implementation

The WBBRS_Implementation worksheet contains the calculations and assumptions that underlie the alternative water budget based rate structures and their estimated water savings.

Section G: WUE Inputs

The WUE_Inputs worksheet contains the planned active conservation savings from the alternative water use efficiency scenarios.

Appendix A: Review of MWD Demand Model

Current econometric model specification

Metropolitan currently uses a customized version of the IWR-MAIN (Municipal and Industrial) sometimes referred to as MWD-MAIN. This demand model features a separate model for different customer sectors—Single Family Residential, Multifamily Residential, and Commercial, Industrial, and Institutional (CII). Table 1 depicts these key relationships in the MWD demand model. In the residential sector, the forecasts of water demand per dwelling unit are ultimately combined with the forecasts of dwelling units from the regional planning agencies to yield an estimate of total sector water demand. Similarly, in the nonresidential sector, water use per employee is combined with forecasts of employment to yield an estimate of total nonresidential water demand.

Table 1 MWD Demand Model Variables

Demand Sector	Projected Demographic	Dependent Variable	Explanatory Variables
Single Family Residential	Number of Single Family Households	Water use per household	Climate Household Size Income Price and Conservation Housing Density Service Area Location
Multifamily Residential	Number of Multifamily Households	Water use per household	Climate Household Size Income Price and Conservation Housing Density Service Area Location
Commercial, Industrial, Institutional (CII)	Total Urban Employment	Water use per employee	Climate Price and Conservation Industrial / Service Employment Share
System Loss / Unmetered Use			Percentage of total use

Each statistical model will be analytically described.

Specification of Single Family Residential Model

The systematic form of the single family residential model is:

Equation 1

$$\ln \frac{Use_{i,t}}{Unit_{i,t}} = \mu_i + \beta_M \cdot Month_t + \beta_W \cdot Weather_{i,t} + \beta_S \cdot SocioEconomic_{i,t} + \beta_D \cdot Drought_t$$

where $\frac{Use_{i,t}}{Unit_{i,t}}$ is the interpolated quantity of single family water use per occupied single family residence of retail agency *i* within month *t*,
the parameter μ_i represents a fixed intercept parameter for each agency *i*,
$Month_t$ is an indicator variable for the month,
$Weather_t$ is weather component,
$SocioEconomic_t$ is a set of socioeconomic measures, and
Drought, are indicator variables for the presence of drought response.

Taking a closer look at each component, the dependent variable is interpolated to reflect the fact that it is a measure taken from billed consumption data. (This type of "sales" data is required for the customer class specific models of MWDMAIN.) The interpolation was performed as follows:

$$\hat{U}se_t = 0.5 \cdot Use_t + 0.5 \cdot Use_{t-1}; monthly\_data$$
$$or$$
$$\hat{U}se_t = 0.25 \cdot Use_t + 0.5 \cdot Use_{t-1} + 0.25 \cdot Use_{t-2}; bimonthly\_data$$

The monthly seasonal component includes 11 binary indicator variables, one for each month:

$$Month_t = Jan + Mar + Apr + May + Jun + Jul + Aug + Sep + Oct + Nov + Dec$$

Since 12 monthly indicator variables are perfectly correlated with the intercept, one must be excluded. Identical predictions are generated no matter which month is excluded; only the interpretation of the monthly coefficients changes.

The weather component is comprised of weather measures (monthly rainfall, rainy days in the month, and air temperature) that are transformed logarithmically with their monthly average subtracted away. Contemporaneous values (rain in the same month as use) as well as lagged values are included.

$$Weather_{i,t} \equiv dlR_{i,t} + dlR_{i,t-1} + dlR_{i,t-2} + lRDays_{i,t} + lRDays_{i,t-1} + dlT_{i,t} + dlT_{i,t-1} + dlT_{i,t-2}$$
$$dlR_{i,t} \equiv \ln(Rain_{i,t} + 1) - \overline{\ln(Rain_{i,t} + 1)}$$
$$lRDays_{i,t} \equiv \ln(number\_of\_rainy\_days\_in\_month + 1)$$
$$dlT_{i,t} \equiv \ln(Temp_{i,t}) - \overline{\ln(Temp_{i,t})}$$

The socioeconomic component for single family residential includes measures of water price, the number of occupied housing units per acre in 1990, the number of persons per household in 1990, and median household income in 1990.

$$Socioeconomic_{i,t} = \ln(real\_marginal\_price_{i,t}) + \ln(\frac{Units_{i,1990}}{Acres_{i,1990}}) + \ln(\frac{Persons_{i,1990}}{Units_{i,1990}}) + \ln(\frac{\overline{Income_{i,1990}}}{Unit_{i,1990}})$$

Because the estimation period included periods of drought, the model controlled for customer response to agency requested curtailments by using additional, agency-specific, binary indicators for voluntary or mandatory curtailments. An additional indicator for the severe drought period 1990-1992 was also included.

$$
\begin{aligned}
Drought_t = {} & IndicatorforVoluntaryConservation_{i,t} + \\
& IndicatorforMandatoryConservation_{i,t} + \\
& IndicatorforDroughtPeriod(1990-1992)
\end{aligned}
$$

The single family residential model was weighted by single family use/deliveries and estimated using ordinary least squares.

Multifamily Residential

The systematic form of the multifamily residential model is:

Equation 2

$$\ln \frac{Use_{i,t}}{Unit_{i,t}} = \mu_i + \beta_M \cdot Month_t + \beta_W \cdot Weather_{i,t} + \beta_S \cdot SocioEconomic_{i,t} + \beta_D \cdot Drought_t$$

where $\frac{Use_{i,t}}{Unit_{i,t}}$ is the interpolated quantity of water use per occupied multifamily residence of retail agency *i* within month *t*, as in the single family model.

The parameter μ_i represents a fixed intercept parameter for each agency *i*,
$Month_t$ is an indicator variable for eleven months,
$Weather_t$ is a somewhat simpler weather component,
$SocioEconomic_t$ is a set of socioeconomic measures, and
$Drought_t$ are indicator variables for the presence of drought response.

The components of the multifamily residential model are somewhat simpler.

$$
\begin{aligned}
& Weather_{i,t} \equiv dlR_{i,t} + dlR_{i,t-1} + dlR_{i,t-2} + dlT_{i,t-1} \\
& dlR_{i,t} \equiv \ln(Rain_{i,t} + 1) - \overline{\ln(Rain_{i,t} + 1)} \\
& dlT_{i,t} \equiv \ln(Temp_{i,t}) - \overline{\ln(Temp_{i,t})} \\
& Drought_t = IndicatorforVoluntaryConservation_{i,t} + \\
& \qquad IndicatorforMandatoryConservation_{i,t}
\end{aligned}
$$

The multifamily residential model was weighted by multifamily use/deliveries and estimated using ordinary least squares.

Nonresidential—CII

For the nonresidential sector, the dependent variable is specified in terms of use per employee.

$$\ln \frac{Use_{i,t}}{Employee_{i,t}} = \mu_i + \beta_M \cdot Month_t + \beta_W \cdot Weather_{i,t} + \beta_S \cdot SocioEconomic_{i,t} + \beta_D \cdot Drought_t$$

In the documentation provided, the *Socioeconomic* component is formed by measures of eight major types of employment (the eight two digit SIC classifications of employment), that are adjusted for changes in productivity. A simpler form of this model is currently being used to generate nonresidential projections; the working form of the nonresidential equation uses (unadjusted) measures of employment for the two largest employment groupings.

The nonresidential model was weighted by nonresidential use/deliveries and estimated using ordinary least squares.

Evaluation of current econometric model specification and estimation

Any water demand model can be described as deriving from a separation of the explanatory variable into systematic and nonsystematic portions: $Y=f(X) + \varepsilon$.

Dependent Variable: Y

This type of "smoothing" will reduce variation in the original measure and can attenuate the effect of explanatory variables that vary monthly (e.g., weather measures). This said, the use of estimated monthly data represents an improvement over the annual or semi-annual measures used in previous MAIN modeling exercises.

Functional Form of Model: f(X)

The only agency-specific parameter is the intercept. This implies that all slope parameters are restricted to be the same for each agency. Though this may not appear to be a very plausible assumption on the face of it, it does reflect some of the difficult choices between available data and the number of parameters that the modeler attempts to estimate. For example, the current model specification imposes the restriction that the seasonal shape is identical for each agency *i*. Thus, in the single family model, each agency will have January use that is 2 percent above its intercept. Further, the weather effect is identical for each agency. It is implausible that inland agencies would have the same response to weather variation that primarily coastal agencies would have.

The weather effect also imposes the restriction that the percentage response to changes in temperature or rainfall are identical throughout the year. It is implausible that rainfall in June would have the same response as rainfall in January. The specification of the climate effects constitutes an area of potential further refinement.

Estimation Method of Model: $\hat{f}$ and ε

It is well known that fixed effect models, such as those used in estimating equations for MWD-MAIN cannot directly yield slope estimates for explanatory variables that only vary cross-sectionally. Thus, the elasticity's attached to variables that do not vary with time—housing density, persons per household, and median household income—are the result of the weighting procedure and a very small amount of cross-sectionally varying agency data from 1990. The signs of the estimated coefficients are correct but I cannot attest to their validity. However, the magnitude and signs of the estimated parameters are within reasonable ranges, based on my professional experience with demand models in the literature and in use nationally. The model would be improved by the use of modern panel data estimators.

Summary

The current MWD-MAIN models represent an improvement over previous models. The evolutionary path of the MWD-MAIN has several promising alternatives for further improvement.

This review was based on documents, interviews, and data provided by Metropolitan. These included:

Development of Water Use Models for the Interim #5 Forecast: Memorandum Report, January 1995, Jack C. Kiefer, Jerzy W. Kocik, Eva M. Opitz, and Benedykt Dziegielewski of PMCL, A report for the Metropolitan Water District of Southern California.

Development of Water Use Models for the Interim #5 Forecast, ADDENDUM REPORT: MWDMOD Implementation and Calibration, May 1995, Jack C. Kiefer, Jerzy W. Kocik, Eva M. Opitz, and Benedykt Dziegielewski of PMCL, A report for the Metropolitan Water District of Southern California.

Development and Verification of Sectorial Water Demand Forecasting Models for the Metropolitan Water District of Southern California, Draft Report, Feb. 1997, Jack C. Kiefer, Jerzy W. Kocik of PMCL, A report for the Metropolitan Water District of Southern California.

Appendix B: Demographic Data Development

Summary Methodology for Socioeconomic Data Disaggregation to IEUA

In fall 2013, the Center for Demographic Research (CDR) at California State University, Fullerton was contracted to disaggregate regional socioeconomic data for a water demand model for the Inland Empire Utilities Agency (IEUA). The specific objectives of this project were to develop estimates and projections of the following variables for 2008 and 2010 through 2035 for the cities, Retail Water Service Agencies, and Wastewater Tributaries within IEUA:

1. Total Population
2. Resident/Household Population
3. Group Quarters Population
4. Households (Occupied Housing Units)
5. Single-Family Households
6. Multi-Family Households
7. Employment (Jobs) by sector:
    a. Agriculture & Mining
    b. Construction
    c. Manufacturing
    d. Wholesale
    e. Retail
    f. Transportation, Warehousing, & Utility
    g. Information
    h. Financial Activity & Real Estate (FIRE)
    i. Professional & Business Services
    j. Education & Health Services
    k. Leisure & Hospitality
    l. Other Services
    m. Public Administration

The projections database used is the Southern California Association of Governments (SCAG) 2012-2035 Regional Transportation Plan/Sustainable Communities Strategy (2012 RTP/SCS), which was allocated to the Traffic Analysis Zones (TAZ).

These were developed by first overlaying the city, water agency, and tributary boundaries on the TAZ boundaries using GIS software. Prior to overlaying the geographies, corrections and adjustments were made to the boundaries to minimize errors and differences.
First, a union of TAZ data to each of the three primary geographies (cities, Retail Service Water Agencies, and Wastewater Tributaries) was done using GIS software. TAZs wholly contained within a primary geography were assigned to that geography.
If a TAZ was split by a primary geography, the TAZ data was redistributed between two or more split polygons using a combination of GIS and Microsoft Excel. To distribute population and housing data, an area allocation method was used and then supplemented with a review of the 2010 aerial photo from ESRI. This was done by counting rooftops of single family detached homes. For multi-family housing,

Google Maps were used to find the property information, and then properties were contacted to obtain the number of housing units in the development.

Population was allocated based on the share of housing units in the split compared to the total number for the original TAZ data. For employment, employer point data from D&B was used which contained the address and number of employees by NAICS code. Each 2-digit NAICS code was assigned to one of the SCAG 13 employment sector categories. These were then subtotaled by the split TAZ geographies, and then controlled by sector to the original TAZ totals.

Summary Methodology for Socioeconomic Data Disaggregation to IEUA 2 of 2
Future growth after 2010 was allocated based on aerial review of open land by TAZ where splits occurred. After all population, housing, and employment data were allocated, the data were joined to each primary geography boundary file using GIS software. Each boundary file (shapefile) was quality-checked to verify the split TAZs correctly followed the source data for each geography type. Finally, the split TAZ data were dissolved on each of the primary geographies for cartographic representation. The outcomes were GIS shapefiles with spatially accurate, allocated population, housing, and employment data for three primary geographies: cities, Retail Water Service Agencies, and Wastewater Tributaries.

1. Total Population- Refers to all persons; sum of resident/household population and group quarters population.
2. Resident/Household Population- Resident population refers to the segment of the population that resides in non-institutionalized quarters, such as single and multiple family units, mobile homes, oats, recreational vehicles, and other miscellaneous types of residences. The resident population is synonymous with household population as defined by the California State Department of Finance.
3. Group Quarters Population- Group Quarters Population refers to the population residing in non-institutionalized group quarters, such as college dormitories, military barracks, convalescent hospitals, and shelters.
4. Total Households (Occupied Housing Units) - Occupied Total Dwelling Units and Households are synonymous. Households were calculated by summing Occupied Single-Family Households and Multi-Family Households.
5. Single-Family Households- Occupied single-family detached housing units.
6. Multi-Family Households- All other occupied housing units (includes single-family attached, multi-family, duplex, triplex, fourplex, mobile homes.
7. Employment: Total number of jobs, includes full time and part time jobs by sector
    a. Agriculture & Mining
    b. Construction
    c. Manufacturing
    d. Wholesale
    e. Retail
    f. Transportation, Warehousing, & Utility
    g. Information
    h. Financial Activity & Real Estate (FIRE)
    i. Professional & Business Services
    j. Education & Health Services
    k. Leisure & Hospitality
    l. Other Services
    m. Public Administration

Boundary Details Documentation

The IEUA official shape file was available for all IEUA-wide demographics.

To get the city boundaries, CDR utilized the RTP city files which are more accurate than the Census Tiger files.

To get the retail service area boundaries, CDR utilized the city files, and then overlaid the non-city water companies (MVWD, FWC, and CVWD).

Then special corrections were made for the following:

- West Valley Water District (northeastern IEUA area)
- Golden State Water Company (border of Upland and MVWD)
- Power Plant (Reliant Energy Etiwanda)
- IEUA facilities (adjacent to power plant)
- Yellowstone Circle (Chino Hills for water and Chino for wastewater)

To get the wastewater tributaries, RMC developed a boundary file in cooperation with IEUA.

Appendix C: Indoor/Outdoor End Uses

Introduction

This Appendix documents the estimation of indoor and outdoor water end uses for water demand in the IEUA service area. This estimation of indoor/outdoor end uses is conducted by customer class—single family residential, multi-family residential, and commercial-industrial-institutional (CII). Indoor end uses are of particular interest to planners tasked with designing wastewater systems and recycled water systems because it helps them establish capacity requirements. Both indoor and outdoor use is of great interest to planners tasked with designing Water Use Efficiency (conservation) programs. Although much has already been accomplished with indoor conservation, there is some level of remaining potential for water savings. WUE planners have particular interest in outdoor use because it is generally assumed to be a large share of total use with large remaining potential for savings.

Two methods were used to estimate outdoor use across customer classes. The first method is the minimum month method that has been historically used in the water industry—this method assumes that the minimum month of water demand is 100 percent indoor end uses. Though we believe that this is a counterfactual assumption in the IEUA service area (it assumes exactly zero outdoor irrigation in the winter) we provide estimates using the minimum month method to serve as a point of comparison. The second method develops an estimate of winter irrigation from dedicated irrigation meters and applies this nonzero assumption instead. Termed a “seasonal variation” method, it applies the seasonal variation from dedicated irrigation meters to mixed meter customer classes.

The seasonal variation method estimates outdoor end uses to compose 62 percent of overall water demand in the IEUA service area. (Presuming all water demand in the minimum month to be all indoor end use would estimate outdoor end uses to be 46 percent of total demand.) We recommend using the seasonal variation method because we know the minimum month method systematically underestimates outdoor water use in climates where there is winter irrigation such as IEUA.

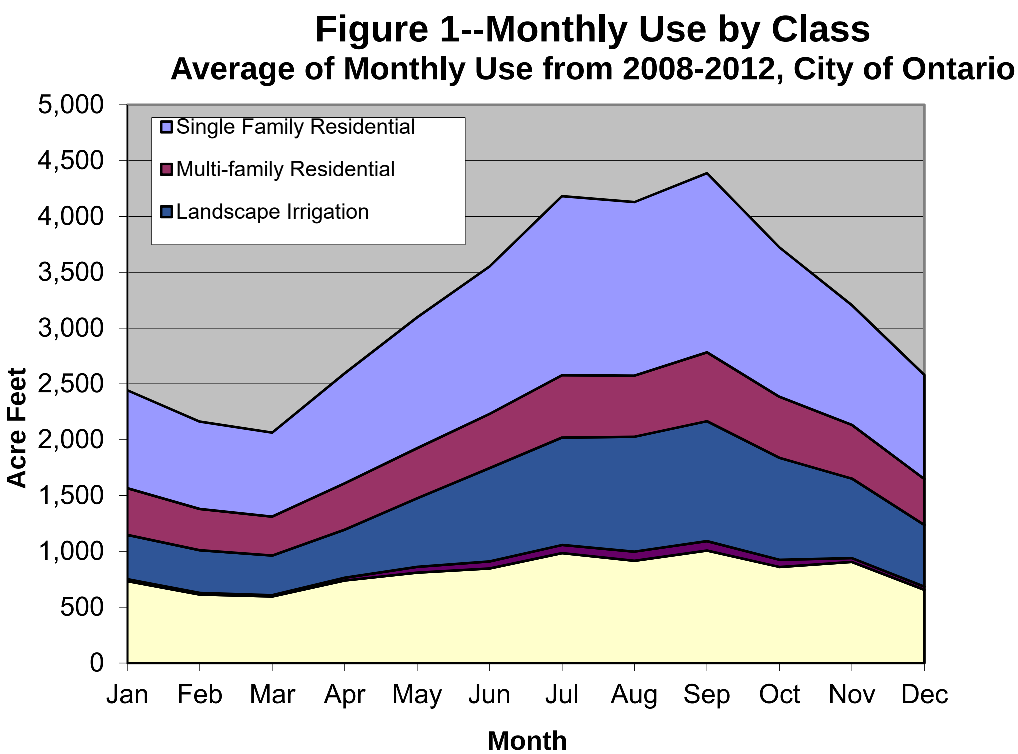
Data

The data used are from the California Department of Water Resources, Public Water System Statistics filings for the City of Ontario for the years 1993 to 2012. These data are billing system summaries at the monthly level. Several other retailers provided monthly use summaries; however, these were generated with bimonthly billing cycles. Since different retailers can apportion bimonthly billing into calendar using different methods, we stick to the monthly data generated with monthly billing.

Table 1 shows the average use from 2008 to 2012 summed by customer class. Figure 1 shows the sum of water use by month. The strong seasonal pattern reflects irrigation needs during the characteristic hot and dry summers.

Table 1 – Average Use, 2008 to 2012, City of Ontario

Class	Use (AF)	Percent
Single Family Residential	13,993	36.7%
Multi-family Residential	5,647	14.8%
Commercial/Industrial/Institutional	9,666	25.4%
Landscape Irrigation	8,259	21.7%
Other	549	1.4%
Total	38,114	100.0%



Methods

Outdoor end uses are directly measured by dedicated irrigation meters. Many other types of water meters--single family, multi family, commercial, industrial, and institutional--can be measuring both indoor and outdoor end uses. If not measured or observed directly, planners are forced to rely on inference or judgment. For IEUA, we have conducted two methods to infer outdoor use for all sectors.

Minimum Month Method

The most common method employed to infer outdoor use is to assume the winter use is all indoors. (This assumption may be closer to the truth in wetter or colder climates.) For example, if we calculate winter minimum use times 12 months we have inferred total indoor use for the year. Total use for the year minus indoor use then equals outdoor use.

In Table 2 below, we find that outdoor use calculated with the “minimum winter use is indoor use” method is 46%. The method underestimates outdoor use because there is likely to be at least some winter irrigation in dry climates. Variations on this method include daily accounting and various ways

to define winter minimum. Note the results of this method will vary considerably from year to year; the reader is cautioned when using results from one year for planning
Purposes and we used for this analysis the monthly average over the five most recent years for which data were available (2008 to 2012).

Table 2 – Percent Outdoor Use

Class	Total	Minimum Month Method	Seasonal Variation Method
Single Family Residential	13,993	36%	58%
Multi-family Residential	5,647	26%	43%
Commercial/Industrial/Institutional	9,666	26%	42%
Landscape Irrigation	8,259	100%	100%
Other	549	75%	100%
Total	38,114	46%	62%

Seasonal Variation Method

The second method to infer outdoor use consists of employing the pattern of seasonal variation with dedicated irrigation meters and applying it to other sectors with mixed meters. The reasoning is that with dedicated irrigation meters we can measure winter irrigation. Thus, we can observe the relative water use in winter and summer irrigation seasons and calculate a parameter from variables that are observable in other sectors. For example, by calculating the ratio of winter minimum to the seasonal range we have a function of variables observable for sectors other than dedicated irrigation meters. This method will result in a higher estimate of outdoor water use than using minimum month. The method relies on the assumption that the seasonal variation of outdoor use is the same for sites with dedicated meters as for sites with mixed meters.
Due to the variability of landscape water use from year to year, we expect the calculated parameter to vary considerably from year to year. For this reason, we calculated the parameter (ratio of winter minimum to seasonal range) for each year for which we could collect data (1993 to 2012) and took the average. We applied this long term average to the monthly average of the most recent five years of consumption data (2008 to 2012) because of the changing distribution of water use by customer class as more dedicated irrigation meters are employed.

Figure 2 shows the use from irrigation-only meters, with winter irrigation illustrated in blue and the seasonal range in red for one example year (2011).

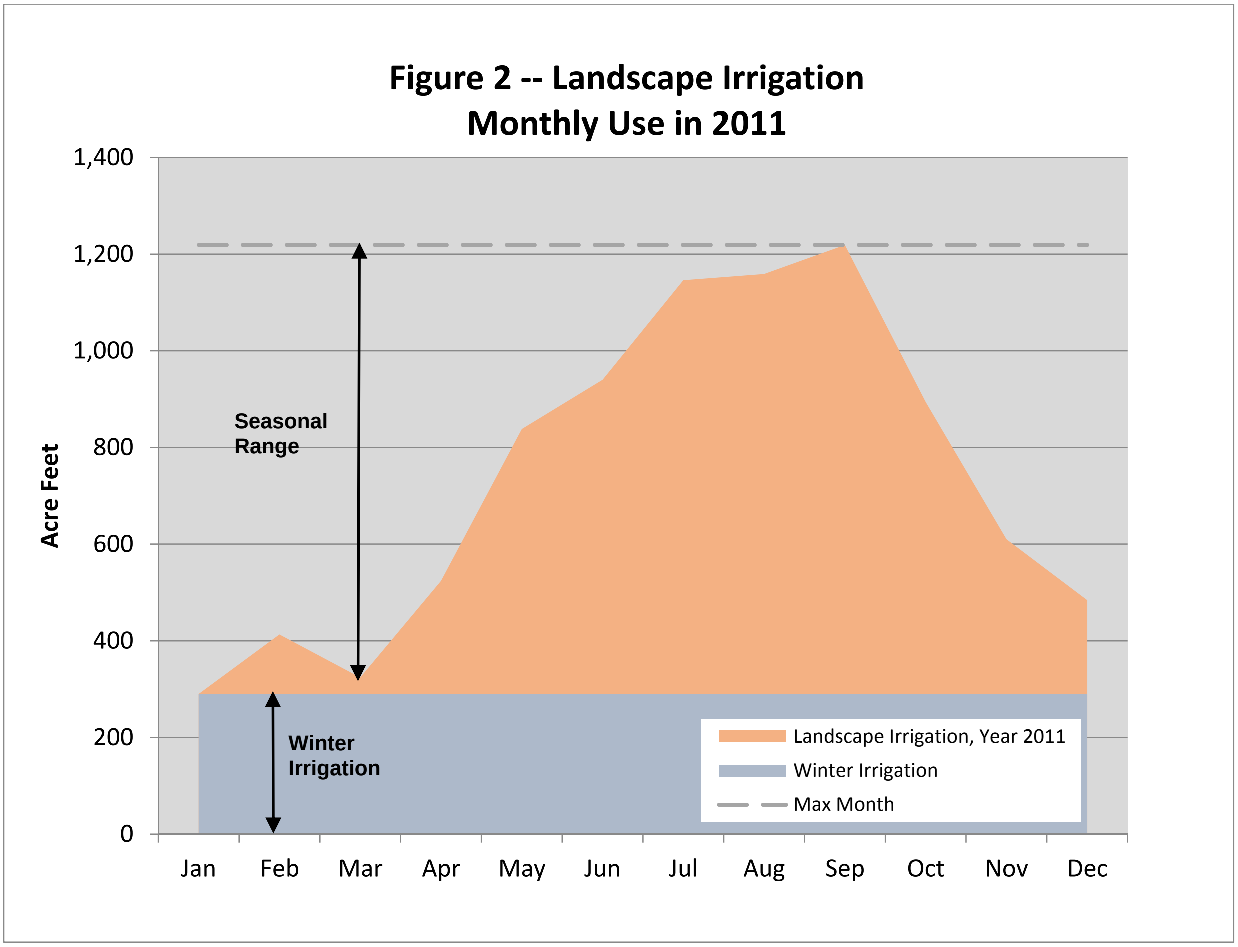


Figure 2 shows winter irrigation is 31% of seasonal range between summer and winter for dedicated irrigation accounts for the year 2011. We repeated this calculation for each year for which were able to collect data (1993 to 2012) and averaged the values to get the result we apply to customer sectors with mixed meters (31%).

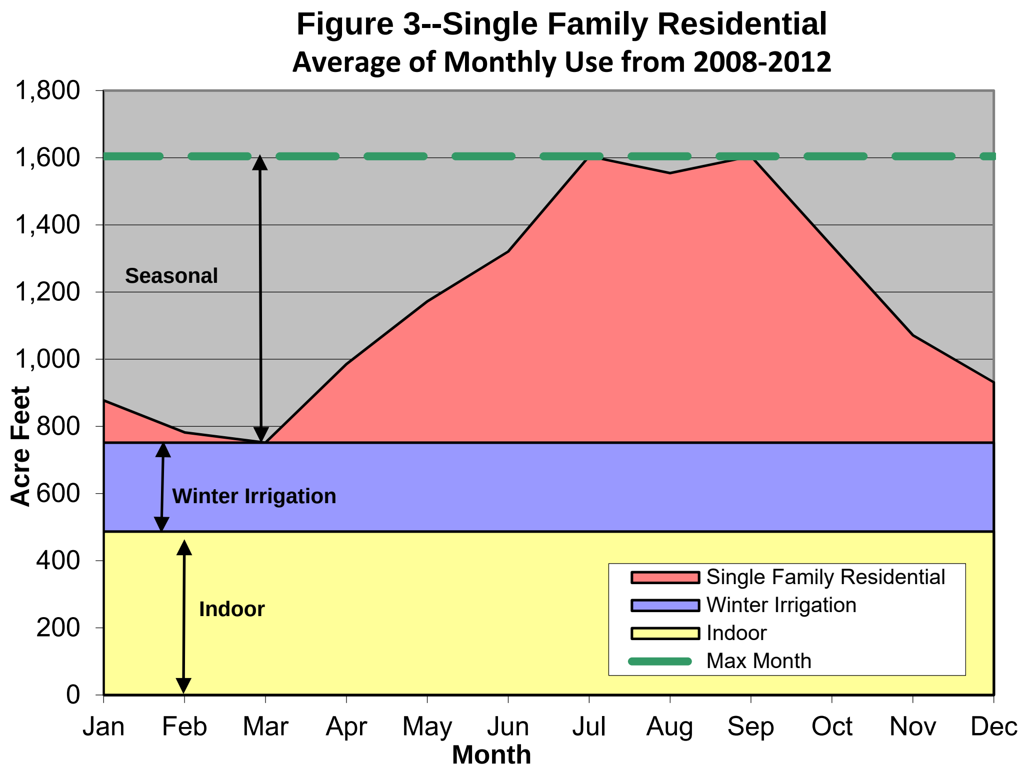
Seasonal range and winter minimum are observable for non-irrigation classes. If we assume that winter irrigation is also 31% of seasonal range for the non-irrigation customer categories, we can infer their winter irrigation, and thus indoor and outdoor use.



For example, Figure 3 shows winter irrigation calculated as 31% of seasonal range for the single family residential sector. Total outdoor use (red+blue in this graph) is, thus, 58% of total use for the year (red+blue+yellow). In contrast, using the minimum month for the single family sector results in 36% outdoor use (red area only).

Recommendations

The minimum month method systematically underestimates outdoor use and overestimates indoor use. As such we do not recommend using it for planning water resource investments in the IEUA service area. Since it is a commonly used method, it may have comparison value. We can improve the reliability of the results by using a longer time series of data to see how the percent outdoor varies from year to year with changes in weather; however, the systematic estimation bias remains.

We recommend the seasonal variation method over the minimum month in this analysis for IEUA because the seasonal variation method does not contain the same source of systematic bias. We have reliable empirical measures using monthly-billed data from one of the larger retail water service areas.

Appendix D: Data Inputs

The following table is from the Parameters_Inputs Worksheet and it summarizes the econometrically estimated parameters that drive the demand equations. Section A defines these parameters in detail. These tables show the socioeconomic inputs from the Base_Forecast Worksheet as described in Section B:

Appendix E: Statistical Analysis of Short Term IEUA Demand: Empirical Estimates of Demand Trends

Introduction

For purposes of quantifying trends in IEUA Demand, one must estimate how water demand responds to predictable variations. There are numerous forces that drive demand growth in the long-term. These include changes in land use patterns and household size, growth in personal income and employment, and price and conservation. Weather conditions tend to make water demand go up or down in any given year.

For use in the Integrated Resource Plan and for calibrating long term water demand forecasts, the IEUA needs depiction of the predictable forces that cause demand to vary in the short-term so as to clarify remaining long term trends. This memorandum describes an empirical model developed to predict daily demand fluctuations. By nature, these models cannot replace long-term predictive models of water demand. However, by providing a better understanding of short-term demand variations, these models can clarify the direction of long term trends. The explanatory variables in this short-term model include:

- Deterministic functions of calendar time, including
  - The seasonal shape of demand
- Weather conditions
  - measures of maximum daily temperature, contemporaneous and time of year
  - measures of rainfall, contemporaneous and time of year
- Measures to control for long-term growth in demand
  - Trend
  - Employment growth different than trend
  - Customer response to voluntary curtailment in 2013 and 2014

The model documented here is used to create high resolution depictions of how variations in weather and the business cycle affect water demand over a wide range of conditions. These model-estimated weather and employment effects can then be used to (1) normalize observed demand and (2) serve as the basis for defining near term variability of demand and any planning dependent upon the trajectory of long term demand.

Data and Methods

Data

Water demand in the IEUA service area is approximated in this analysis as the sum of delivered supplies. This modeling effort used consistent system-wide monthly data—that is monthly water production adjusted for changes in storage. The reader is urged to keep in mind that though these models maybe described as “demand” models, the data on which these models are estimated would be better described as “supply” measures. To the extent that storage issues can be accounted for, the difference between these two constructs should be made small. Nonetheless, the issue remains.

The second major issue with using production data is the level and magnitude of noise in the data. The data generating mechanism for recording production can change over time as flow meters age or are replaced. Constructing a consistent time series requires matching two different—and possibly inconsistent—time-series. The records of flow can also embed non-ignorable meter miss-measurement.

To keep data inconsistencies from corrupting statistical estimates of model parameters, this modeling effort employed a sophisticated range of outlier-detection methods and models.

Specification

A Model of Per Capita Water Demand

The model for IEUA per capita water demand seeks to separate several important driving forces. In the short run, changes in weather can make demand increase or decrease in a given year. In the long run, increased population can drive demand higher. Strong regional economic growth can increase water demand through additional commercial or industrial water use. In addition, a rising economic tide can broadly increase personal income levels and economic activity can encourage or discourage additional population growth. Changes in water rates will change the relative attractiveness of water conservation.

These models are estimated at an aggregate level and, as such, should be interpreted as a condensation of many types of relationships — meteorological, physical, behavioral, managerial, legal, and chronological. Nonetheless, these models depict key short-run and long-run relationships and should serve as a solid point of departure for improved quantification of these linkages.

Systematic Effects

This section specifies a water demand function that has several unique features. First, it models seasonal and climatic effects as continuous (as opposed to discrete monthly, semi-annual, or annual) function of time. Thus, the seasonal component in the water demand model can be specified on a continuous basis, then aggregated to a level comparable to measured water use (e.g. monthly). Second, the climatic component is specified in "difference" form as a similar continuous function of time. The climate measures are thereby made independent of the seasonal component. Third, the model permits interactions of the seasonal component and the climatic component. Thus, the season-specific response of water use can be specific to the season of the year.

The general form of the model is:

Equation 2

$$PerCapitaWaterUse_t[GPCD] = \frac{Use_t}{Pop_t} = f(S_t + C_t + T_t)$$

where ***Use*** is the volumetric quantity of retail water use within time *t*, $\boldsymbol{S_t}$ is a seasonal component, $\boldsymbol{C_t}$ is a climatic component, and $\boldsymbol{T_t}$ is the trend component of GPCD Demand. The function *f* is the functional form of the connection between per capita water use and its explanatory components. Each of these components is described below.

Seasonal Component: A monthly seasonal component could be formed using monthly dummy variables to represent a seasonal step function. Equivalently, one may form a combination of sine and cosine terms in a Fourier series to define the seasonal component as a continuous function of time.[1] The following harmonics are defined for a given day *T*, ignoring the slight complication of leap years:

[1] The use of a harmonic representation for a seasonal component in a regression context dates back to *Hannan* [1960]. *Jorgenson* [1964] extended these results to include least squares estimation of both trend and seasonal components.

Equation 3

$$S_t \equiv \sum_{1}^{6}\left[\beta_{i,j}\cdot\sin\left(\frac{2\pi\cdot jT}{365}\right)+\beta_{i,j}\cdot\cos\left(\frac{2\pi\cdot jT}{365}\right)\right]=Z\cdot\beta_S$$

where T = (1,...365) and j represents the frequency of each harmonic. Because the lower frequencies tend to explain most of the seasonal fluctuation, the higher frequencies can often be omitted with little predictive loss.

The percentage effect of the seasonal component on normal demand is given by:

Equation 3

$$S_t\% = \left[\frac{\exp(\widehat{Y}_t - T_t) - \exp(\widehat{Y}_t - T_t - S_t)}{\exp(\widehat{Y}_t - T_t - S_t)}\right]$$

where $\widehat{Y}$ is the predicted demand.

Climatic Component: The model incorporates two types of climate measures into the climatic component–rainfall and maximum daily air temperature.[2] The measures of temperature and rainfall are then logarithmically transformed to yield:

Equation 4

$$R_t \equiv \ln\left[1+\sum_{t=T}^{T_d} Rain_t\right], T_t \equiv \ln\left[\sum_{t=T}^{T_d}\frac{T_t}{d}\right]$$

Though this model extends to monthly measures while for daily measures, d takes on the value of one. Because weather exhibits strong seasonal patterns, climatic measures are strongly correlated with the seasonal measures. In addition, the occurrence of rainfall can reduce expected temperature. To obtain valid estimates of a constant seasonal effect, the seasonal component is removed from the climatic measures by construction.

Specifically, climatic measures are constructed as a departure from their "normal" or expected value at a given time of the year. The expected value for rainfall during the year, for example, is derived from regression against the seasonal harmonics. The expected value of the climatic measures ($\hat{\boldsymbol{C}}=\boldsymbol{Z}\cdot\beta_C$) is subtracted from the original climatic measures:

Equation 5

$$C_t \equiv (R_t - \widehat{R}_t)\cdot\beta_R + (E_t - \widehat{E}_t)\cdot\beta_T$$

The climatic measures in this deviation-from-mean form are thereby separated from the constant seasonal effect.[3] Thus, the seasonal component of the model captures all constant seasonal effects, as it

[2] Specifically it uses the daily temperature and the total daily precipitation at the Ontario NOAA station summarized to a monthly level.

[3] The logarithmic transformation of the original climate variable implies that the seasonal mean climate effect is a geometric mean. Because the model is estimated on the logarithmic scale the departure-from-mean climatic effects would be more accurately termed departure-from-median. See *Goldberger* [1968].

should, even if these constant effects are due to normal climatic conditions. The remaining climate measures capture the effect of climate departing from its normal pattern.

The model can also specify a richer texture in the temporal effect of climate than the usual fixed contemporaneous effect. Seasonally-varying climatic effects can be created by interacting the climatic measures with the harmonic terms. In addition, the measures can be constructed to detect lagged effects of climate, such as the effect of rainfall a month ago on today's water demand.

The percentage effect of the climate on normal demand is given by:

Equation 6

$$C_t\% = \left[\frac{\exp(\hat{Y}_t - T_t) - \exp(\hat{Y}_t - T_t - C_t)}{\exp(\hat{Y}_t - T_t - C_t)}\right]$$

where $\hat{Y}$ is the predicted demand.

Trend Component : For the IEUA Demand model, a deterministic annual trend term was used as the primary determinant of trends in per capita water demand in the long term.

Equation 7

$$\mathbf{T}_t \equiv AnnualTrend_t \cdot \beta_T + (\ln EmpDetrended) \cdot \beta_E$$

Thus the annual long term trend in IEUA Demand from 2002-2012 on is captured by β_T while the effects of the business cycle are captured by the departure of employment from its long term trend.

Stochastic Effects

To complete the model, we must account for the fact that not every data point will lie on the plane defined by Equation **(1)**. This fundamental characteristic of all systematic models can impose large inferential costs if ignored. Misspecification of this “error component” can lead to inefficient estimation of the coefficients defining the systematic forces, incorrect estimates of coefficient standard errors, and an invalid basis for inference about forecast uncertainty. The specification of the error component involves defining what departures from pure randomness are allowed. What is the functional form of model error? Just as the model of systematic forces can be thought of as an estimate of a function for the “mean” or expected value, so too can a model be developed to explain departures from the mean—i.e., a “variance function” If the vertical distance from any observation to the plane defined by **(1)** is the quantity $\boldsymbol{\varepsilon}$, then the error component is added to Equation **(1)**:

Equation 8

$$\ln \frac{Use}{Pop} = \mathbf{f}\left(\mathbf{S}_t, \mathbf{C}_t, \mathbf{T}_t\right) + \varepsilon$$

In an Ordinary Least Squares (OLS) Regression, the error term is assumed to be distributed normally with a constant variance.

$$\varepsilon \sim N\left(\mu_\varepsilon, \sigma_\varepsilon\right)$$

In the estimated retail demand model below, the variance is allowed to be nonconstant and separately modeled as an empirical variance (or link) function.

$$\sigma_{\varepsilon} = g(\mathbf{S}_t, \mathbf{C}_t, \mathbf{T}_t)$$

A variance function was estimated using the methods of Carroll and Ruppert as a two stage weighted least squares regression[4]. Briefly described, the first stage uses an OLS regression of the mean function (Equation 7) to derive a consistent estimate of the estimated error. The absolute value of the estimated error is used to estimate the variance function. The inverse of the predicted variance is used to weight the regression of the mean function in the second stage.

Estimated Per Capita Demand Model for IEUA

Table C1 presents the estimation results for the model of mean monthly per capita demand in IEUA. The independent variables 1 to 8—made up of the sines and cosines of the Fourier series described in Equation 2—are used to depict the seasonal shape of daily retail water demand (that is, $Z \cdot \widehat{\beta}_S$); this is the shape of demand in a normal weather year. This seasonal shape is important in that it represents the point of departure for the estimated climate effects (expressed as departure from what is expected in an average month).

The estimated weather effect is specified in "departure-from-normal" form. Variable 9 is the departure of monthly precipitation from the average precipitation for that month in the season. (Average seasonal precipitation is derived from a regression of monthly precipitation on the seasonal harmonics—exactly equal to monthly precipitation averaged over all years in the record.) Temperature is treated in an analogous fashion (Variables 11). The contemporaneous weather effect is interacted with the harmonics (Variables 10, 12, and 13) to produce a seasonal shape to both the rainfall and the temperature elasticities. Thus, departures of temperature from normal produce the largest percentage effect in the spring. Similarly, departures from normal rainfall produce a larger effect upon daily demand in the summer than in the winter. The lagged effect of temperature can also be detected further in time than rainfall—a detectable effect one month long.

The departure of employment growth from trend (13) and the annual trend term (variable 14) and comprise the long term determinants of demand.[5] Indicators ("dummy") variables for the years 2013 and 2014 were used to detect any customer response to the drought-induced calls for voluntary demand curtailment. (These measure the annual change in demand that was surprising: not explainable due to weather variation, recession, or ongoing trends in demand.) The constant term (17) describes the intercept for this equation.

[4] See Carroll, R. J. and Ruppert, D. (1988). *Transformation and Weighting in Regression*. Chapman and Hall, London.

[5] A variation of the model was used to test for a detectable trend in the seasonal shape of demand by including an interaction of the trend term and the annual harmonic.

Table 1-- Estimated IEUA Per Capita Demand Model (Mean Function)

Estimated IEUA Demand Model (Mean Function) Ln IEUA Per Capita Use (Gl. Per Capita Per Day)		
Independent Variable	**Coefficient**	**Std. Error**

Figures 1 and 2 plot Actual IEUA Per Capita Demand against the model predictions ($\hat{Y}$) and reveals a very tight fit of predictions to actual.

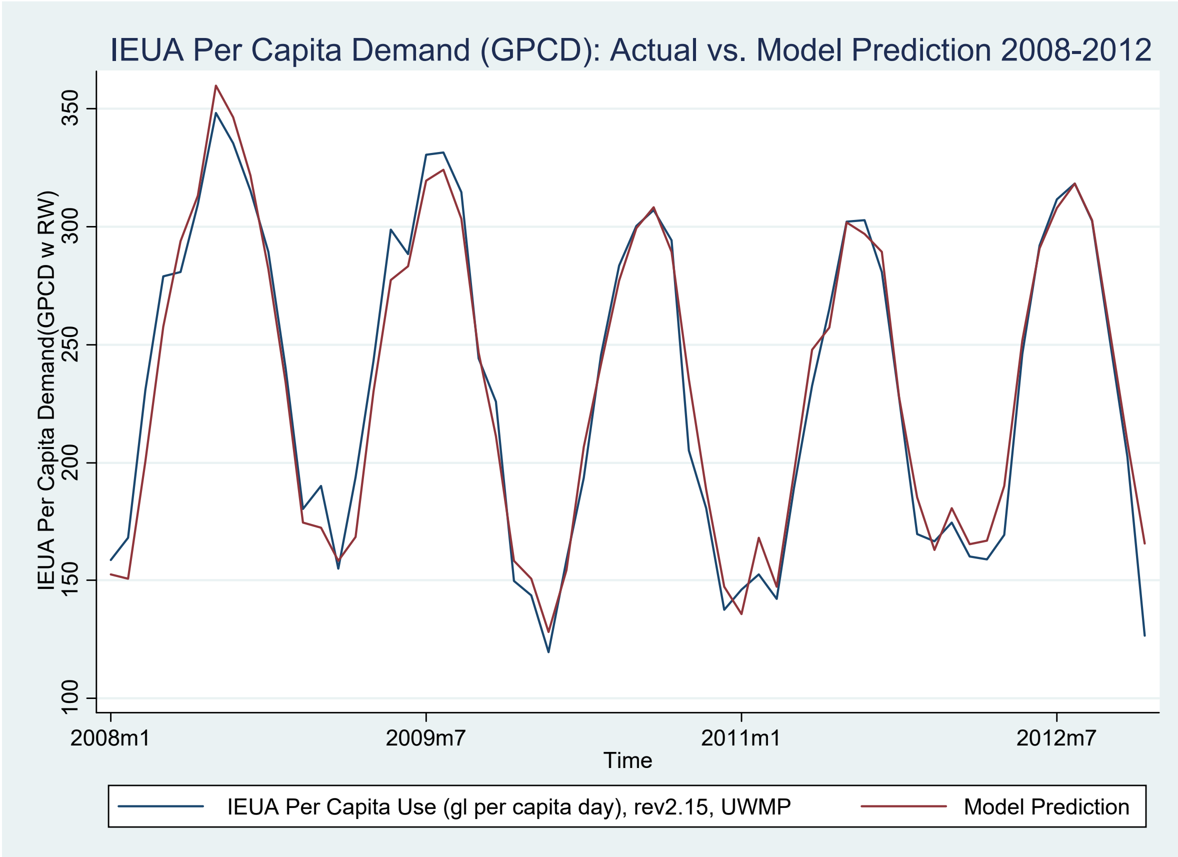

Figure 1-- IEUA Per Capita Demand (GPCD): Actual vs. Model Prediction , FY 2008-2012

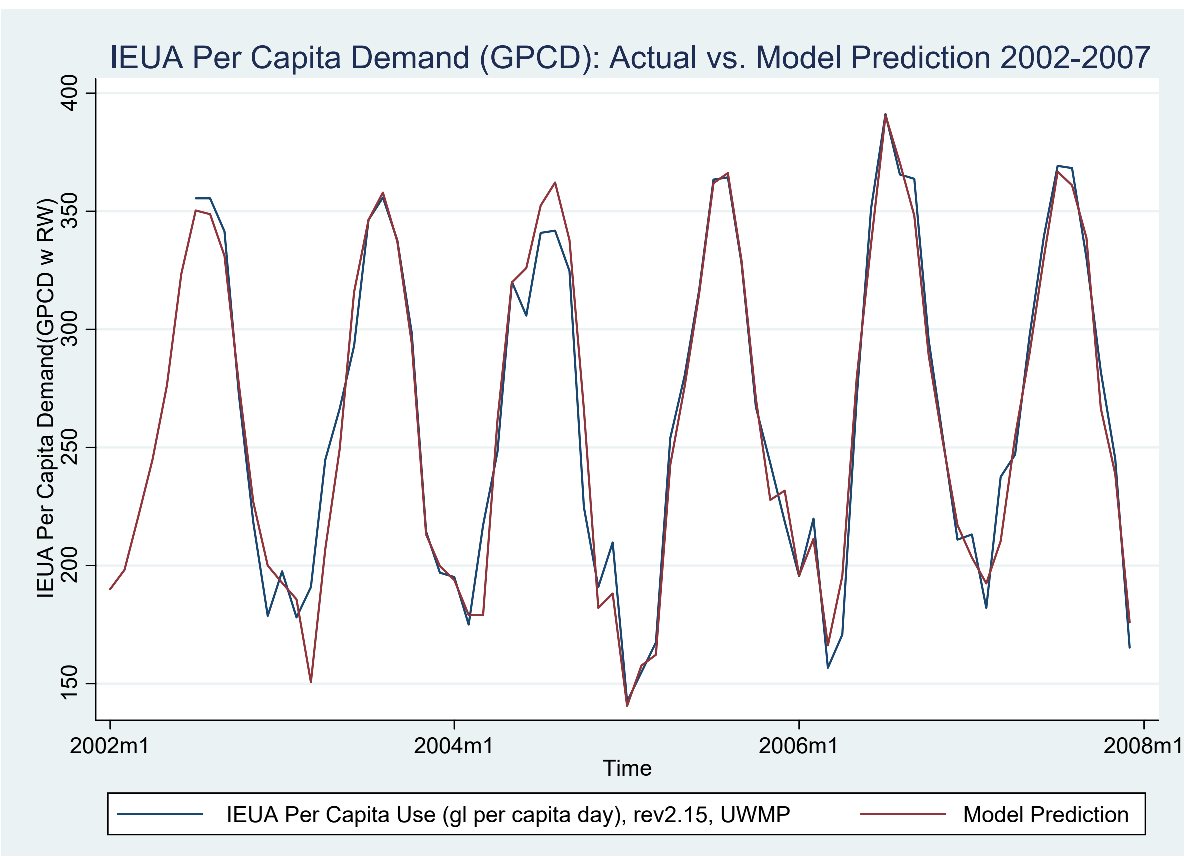

Figure 2-- IEUA Per Capita Demand (GPCD): Actual vs. Model Prediction , FY 2002-2007

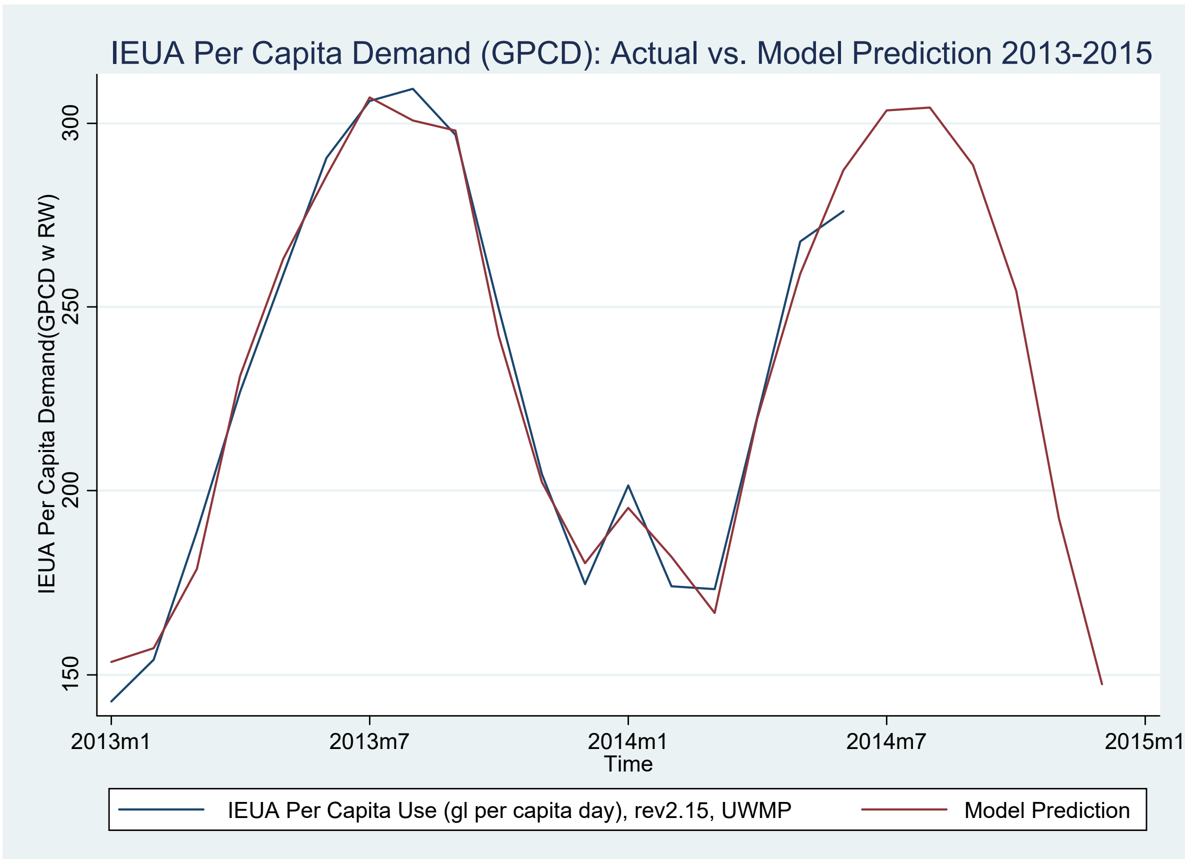

Figure 3-- IEUA Per Capita Demand (GPCD): Actual vs. Model Prediction, 2013-2014

Application to Demand Trends

From the statistically estimated model documented above, one can calculate the effect of weather on per capita water demand as the difference between two predictions: a prediction of demand conditional on actual weather and a prediction of demand “as if” weather were normal[6]. Equation 5 specifies this relationship in percentage terms. Table 2 presents the summation of the estimated effect of weather for each year.

[6] Normal weather is defined as the average values of each weather variable in each month over the period of record 1950-2012.

Table 2-- Effect of Weather on IEUA Per Capita Demand (GPCD)

IEUA Water Demand (GPCD)				
	IEUA Water Demand			
Year	Effect of Weather on Water Demand (Change in GPCD)	Effect of Weather on Water Demand (Percent)	Precipitation (inches)	Max Temperature (F)
2003	-22.85	-0.75%	16.71	77.15
2004	114.88	3.58%	8.66	79.71
2005	-170.88	-5.73%	28.20	76.19
2006	-10.02	-0.32%	12.78	78.15
2007	190.90	5.70%	3.73	79.78

Long Term Average	2003-2014		11.84	78.6
Weather Station	Ontario NOAA			

Finally, these estimated effects of non-normal weather and employment different from trend are next used to estimate what per capita water demand would have been if weather had been normal and if employment had not differed from its historical trend (that is, if the recession had not occurred.) Actual demand with weather and employment effects removed will be referred to as “normalized” per capita water demand. Figure 4 below plots the mean monthly employment for San Bernardino County and reveals the sharp effects of the recent recession.

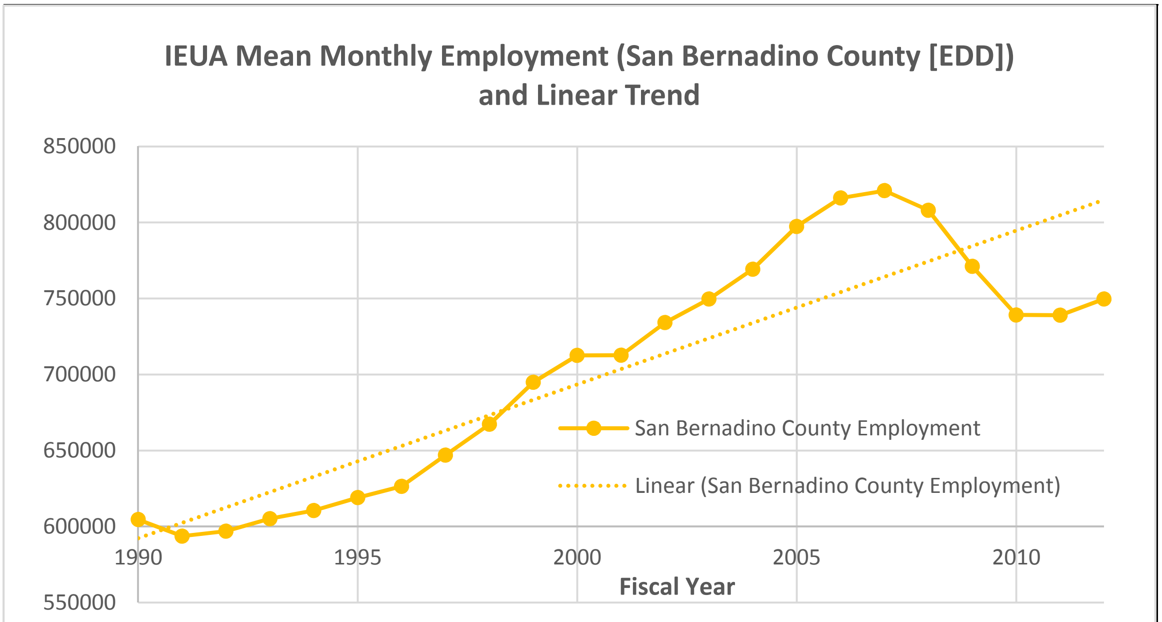

Figure 4-- IEUA Mean Monthly Employment (San Bernardino County [EDD]) and Linear Trend

Table 3 presents the derivation of normalized IEUA per capita water demand. The first column of raw demand data ("Actual Demand") is followed by demand normalized for weather. The estimated percentage effect of weather different from normal ("Effect of Weather on Water Demand (Percent)") explains how weather affected actual demand and is used to estimate the third column of retail demand ("Demand Normalized for Weather (GPCD)"). A similar estimate for the effect of employment different than trend is used to estimate the last column of retail demand ("Demand Normalized for Weather and Employment"). The assumptions implied by this "normalization" include that realized weather is exactly equal to average weather (monthly averages based on the period of record 1950-2012) and that employment continued along its long term trend (as depicted by the straight line in Figure 3).

Note that the variation of the percentage annual effect of weather and employment is summarized at the bottom of the table and is useful for risk analysis. Weather could knock per capita demand 7.3 percent either way in any year (90 percent confidence interval). The effect of the business cycle—as captured by the effect of employment swings—is very pronounced in recent years due to the Great Recession. Single year swings of 5 and a half percent occurred more than once with a very wide confidence interval required to contain 90 percent of expected annual variation due to employment variation (approximately 12.8 percent either way in any year).

The model also detects customer response in 2013 and 2014 to drought-induced calls for customers to voluntarily curtail water demand. These effects, though targeted mostly to residential customers, provide evidence of some customer response that cannot be explained by the other forces in the model—weather variation, variation in employment, and long term trends in water demand.

Table 3-- IEUA Per Capita Use (GPCD): Actual and Normalized

	IEUA Water Demand				
Fiscal Year	Actual Demand (GPCD)	Effect of Weather on Water Demand (Percent)	Demand Normalized for Weather (GPCD)	Effect of Employment on Water Demand (Percent)	Demand Normalized for Weather and Employment (GPCD)
2003	257.77	-0.75%	259.7	4.54%	247.92
2004	267.63	3.58%	258.1	5.64%	243.51
2005	245.78	-5.73%	259.9	7.71%	239.83
2006	262.56	-0.32%	263.4	8.70%	240.47
2007	283.06	5.70%	266.9	8.11%	245.29
2008	265.58	1.40%	261.9	5.52%	247.43
2009	256.55	3.70%	247.1	0.10%	246.82
2010	228.42	-0.56%	229.7	-5.56%	242.47
2011	212.70	-2.89%	218.8	-7.04%	234.25
2012	220.83	0.52%	219.7	-7.08%	235.24
2013	231.40	5.05%	219.7	-6.06%	233.03
2014	237.75	6.97%	221.2	-5.25%	232.80
	Standard Deviation of % Effects	**+/- 3.74%**		**+/- 6.55%**	
	95% Confidence Interval	**+/- 7.3%**		**+/- 12.8%**	
Percentage Annual Trend, FY2003-2007	2.4%			0.7%	-0.3%
Percentage Annual Trend, 2007-2012	-2.7%			-3.8%	-0.8%

Table 4 presents the same results as in Table 3, but in terms of acre feet rather than GPCD. Again, the first column of raw demand data ("Actual Demand") is followed by demand normalized for weather. The estimated percentage effect of weather different from normal ("Effect of Weather on Water Demand (Percent)") explains how weather affected actual demand and is used to estimate the third column of retail demand ("Demand Normalized for Weather (AF)"). A similar estimate for the effect of employment different than trend is used to estimate the last column of retail demand ("Demand Normalized for Weather and Employment").

Taken from "peak to trough," from 2007 to 2012, Table 4 also shows the decline in actual demand was an average of 4.3 percent per year, for a total of 19.6 percent decline over the five-year period. After normalizing for weather and employment, the decline was an average of 0.2 percent per year, or about a one percent decline over the five-year period.

The effect on the trend in per capita demand is easier to discern in Figures 4 and 5. Figure C5 plots actual and normalized demand in terms of GPCD. The near three percent annual decline (2.7 percent) in actual GPCD demand between fiscal years 2007 and 2012 is reduced in magnitude to less than one percent decline (0.8 percent) after normalizing for weather and employment. Figure 5 plots actual and normalized demand in terms of acre feet. The decline in actual demand (in acre feet per year) between fiscal years 2007 and 2012 was 4.3 percent per year on average. After normalizing for weather and employment, there was actually a slight decrease of 0.2 percent.

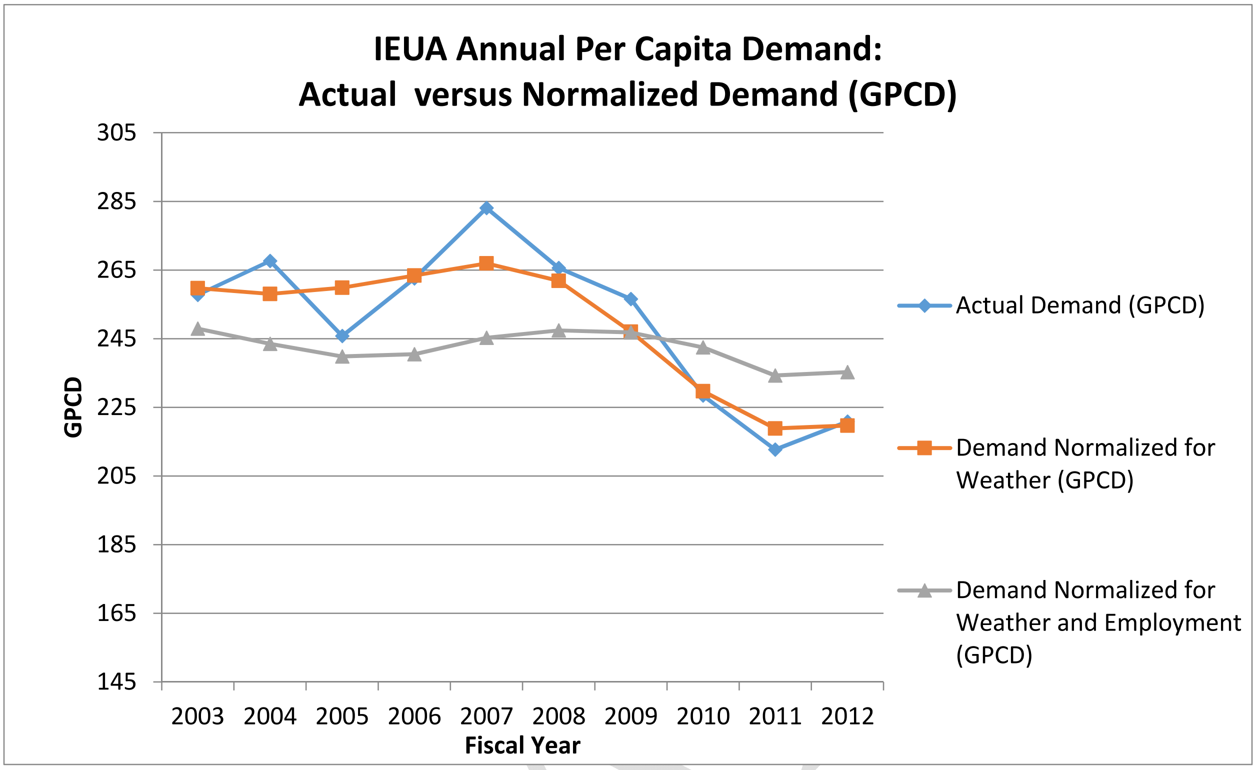

Figure 5-- IEUA Annual Per Capita Demand: Actual versus Normalized Demand (GPCD)

Project Report

Evaluating Options for Improving the Climate Resilience of the Inland Empire Utilities Agency in Southern California

Abbie H. Tingstad, David G. Groves, and James Syme (RAND Corporation)
Elizabeth Hurst and Jason Pivovaroff (Inland Empire Utilities Agency)

March 2016

Preface

The Inland Empire Utilities Agency (IEUA) and RAND worked together in 2003-2005 to demonstrate and evaluate how new approaches to decisionmaking under uncertainty could help a water utility evaluate the potential threats of climate change in their long-term planning. This work was performed outside IEUA's planning process and was documented in several RAND reports and scientific journal articles (Groves, Davis, *et al.*, 2008; Groves, Knopman, *et al.*, 2008; Groves, Lempert, *et al.*, 2008). In 2015, IEUA asked RAND to help it re-evaluate its water management system under a range of future conditions reflecting climate change and other drivers for its Integrated Resources Plan (IRP). This report documents the tools developed and analysis performed during 2015 for this effort. Questions or comments about this report should be sent to the project leaders, David Groves (groves@rand.org) and Abbie Tingstad (tingstad@rand.org).

Introduction

Water managers continue to face challenges related to climate non-stationarity (Milly *et al.*, 2008) in their long-term planning. Even when water supplies appear sufficient to meet present and short-term demand, uncertain future changes in temperature and precipitation make decisions about investments to ensure longer-term supply sufficiency difficult. In Southern California, the recent drought has refocused attention on water resources in this semi-arid, populous area. Although this drought appears to be consistent with long-term patterns of climate variability, its effects may be exacerbated by ongoing climate change, which is anticipated to have a strong effect on the region, including on its water supplies (e.g., with respect to the length and magnitude of droughts, timing of precipitation, and temperature-driven demand) (Diffenbaugh *et al.*, 2015; Mao *et al.*, 2015; Shukla *et al.*, 2015)

Adaptive management plans are designed to evolve over time in response to new information regarding future conditions. This type of flexible approach is becoming increasingly favored in the water management community as a mechanism for planning under uncertainty. Integrative approaches, which help facilitate adaptive plans, focus on combining a variety of management options, rather than a single type of solution.

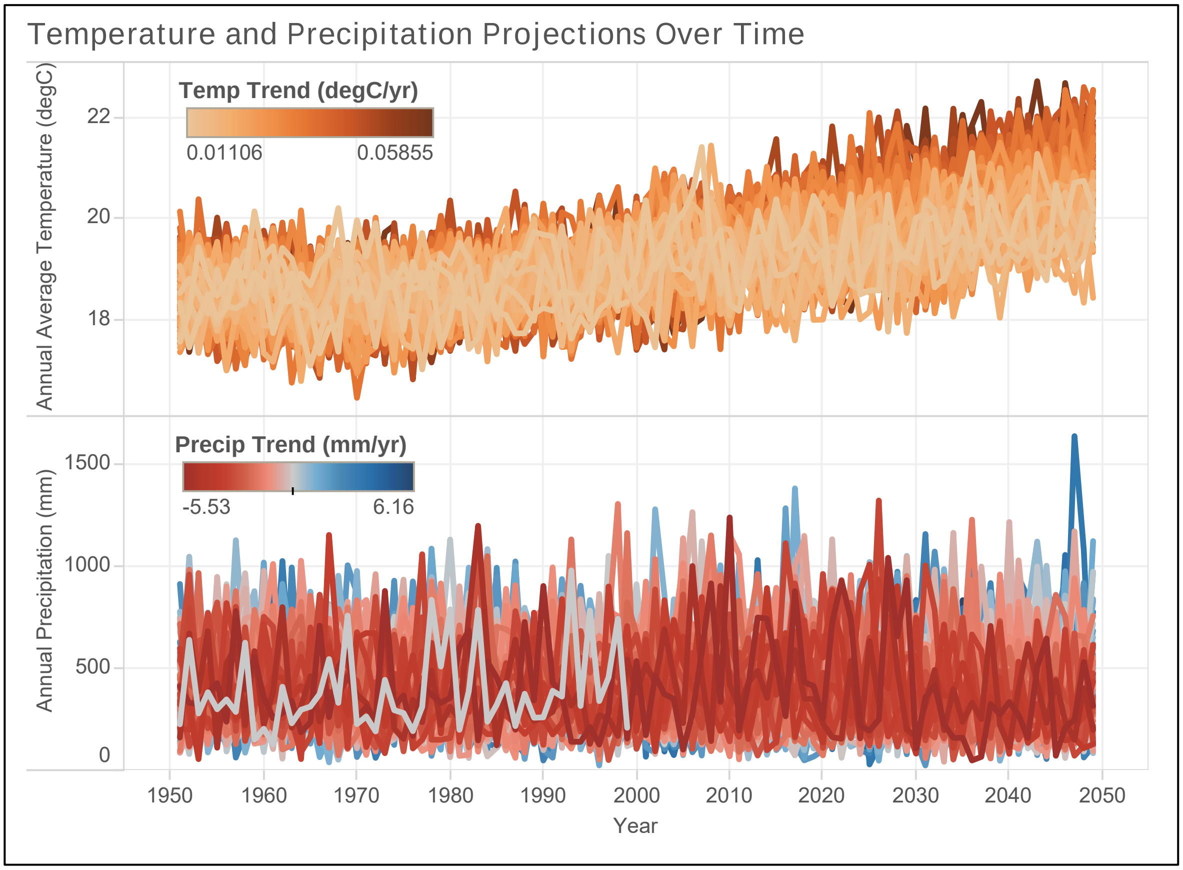
The Inland Empire Utilities Agency (IEUA), a water management agency in Southern California, recently partnered with the RAND Corporation, a multi-disciplinary, non-partisan research organization and educational institution headquartered in Santa Monica, California, to evaluate how adaptive, integrative water management options could improve IEUA's abilities to meet customer needs under a wide range of futures. This analysis was used to support the development of its Integrated Resources Plan (IRP). The purpose of the IRP is to evaluate the resiliency of water resources in the IEUA's service area over the next twenty-five years and to evaluate alternative management options for ensuring water deliveries to urban users. The IRP results will be used to recommend regional strategies and identify preferred water supply projects that, in turn, will help the IEUA and its member agencies to apply for grants and loans to implement new projects. RAND supported IEUA's IRP by developing a tool for constructing and visualizing different portfolios for water management investments and actions, and enabling an analysis of *status quo* and potential future water management activity success in meeting future urban water demand under different demand and climate change-impacted water supply conditions. This follows RAND's previous work supporting the IEUA's 2005 Urban Water Management Plan (UWMP) (Groves, Knopman, *et al.*, 2008; Groves, Lempert, *et al.*, 2008).

Current water demands in the IEUA service area are serviced by groundwater from the Chino Basin in addition to local surface supplies, recycled water, and imported water from Northern California via Metropolitan Water District of Southern California (MWD). In addition, IEUA implements water efficiency projects, such as low-flow toilet rebate programs. Depending on different estimates of future infrastructure water efficiency, this “baseline” supply (current and planned supplies from groundwater and other sources plus savings from water efficiency projects) is likely sufficient, or very nearly so, for meeting future demand assuming climatic conditions remain similar to those experienced in recent history. However, IEUA wanted to explore how shifts in stationarity assumptions through climate change, along with possible changes in demand, could impact its future water supplies and demands, and what water management projects could help meet future demand under uncertain future temperature and precipitation conditions.

A suite of global climate models suggests that temperatures over the IEUA service area will rise over the coming decades and that annual precipitation will continue to be highly variable, with no consensus on trends towards wetter or drier conditions. Figure 1 displays the annual average temperature and total precipitation estimates from 1950 to 2050 for the IEUA service area based on 106 downscaled projections of climate from a range of general circulation models (GCMs).[1] The temperature increases seen beginning around the 1980s and the uncertainty associated with local precipitation underscores the importance of carrying out an analysis of IEUA water management options to ensure that future demand can be met under a variety of different hydrologic circumstances against the backdrop of rising temperatures.

[1] Note that GCMs are not expected to simulate the precise interannual fluctuations of the historical period, because stochastic forces and sequences of events that are unresolvable by numerical models drive such historical variability. Instead, GCMs are validated based on their ability to characterize the statistical characteristics of historical climate, such as maximum and minimum temperatures or precipitation.

Figure 1: Estimates of historical and future annual average temperature and total precipitation for the IEUA service area



To support this analysis we developed (1) a simple mass balance water management model to estimate future supplies and demand across different future and (2) a decision support tool to help IEUA planners and stakeholders to compare attributes of different management options and develop portfolios for evaluation. We then performed a three-step analysis:

1. Evaluated the performance of the IEUA system under a wide range of futures to evaluate its vulnerability to climate and future demand
2. Constructed portfolios of water management projects that could help increase water management supplies in the future
3. Tested and compared how each proposed water management portfolio enhances the IEUA's ability to deliver urban water supplies in the future

In the next section we describe the methods and models used in each step. Due to the limited scope of this effort, we did not attempt to evaluate the cost-effectiveness or finer details (e.g., implementation potential at specific locations) of the different water management projects. We also did not conduct statistical analysis to determine the specific climatic conditions most conducive to different portfolio success or failure in meeting urban water demand, nor did we consider uncertainties related to budget and/or other factors that could impact our results.

Methods

The overarching methodological framework for this project is Robust Decision Making (RDM) (Groves and Lempert, 2007; Lempert *et al.*, 2003). RDM is an approach that seeks to determine what plans reduce risk over a range of assumptions, thereby facilitating deliberation among stakeholders that may have differing values and expectations about the future (Lempert, 2013). It is a methodological process, involving iterative steps including stakeholder interactions, modeling, and statistical analysis, that facilitates interactions and aims to shape decision-maker discussions around which factors lead to plan success or failure and the identification of robust solutions – those that perform well under a range of futures—rather than a single “best” solution (Hallegatte *et al.*, 2012; Lempert *et al.*, 2006). The RDM approach runs models on tens to thousands of different sets of assumptions to describe how plans perform in a range of plausible futures. Analysts then use visualization and statistical analysis of the resulting large database of model runs to help decision-makers distinguish future conditions in which their plans will perform well from those in which they will perform poorly (Bryant and Lempert, 2010). RDM has been used in a range of contexts, to include water management, flood risk assessment, and sea level rise planning (Groves *et al.*, 2013, 2014; Herman *et al.*, 2015; Tingstad *et al.*, 2013).

Many RDM analyses are conceptually organized using a framework called “XLRM”, where key uncertainties (X), policy levers or strategies (L), relationships or models (R), and metrics or outcome measures (M) are summarized in a quad chart. The principal considerations around which this project is organized are summarized in XLRM format below.

Table 1: Summary of uncertainties, projects, models, and outcome measures considered

Uncertainties (X)	Projects (L)
Climate conditions Demand	75 different projects in categories • Chino Basin projects (13) • Imported Water Direct, Imported Water Recharge (14) • Imported Water Recharge (3) • Imported Water Recharge / Recycled Water (4) • Local Surface (2) • Other Groundwater (1) • Recycled Water (16) • Stormwater (6) • Stormwater, Recharge, Imported Water Recharge, Recycled Water (4) • Water Use Efficiency (10) • Chino Basin Groundwater, Recycled Water, Imported Water (2)

Water Management Mass Balance Model

RAND developed a water management model developed for the IEUA service area using a simulation platform called the Water Evaluation and Planning system (WEAP) (Yates *et al.*, 2005). The purpose of this model was to help address Step One of our analysis by creating a simulation model that could evaluate the performance of the IEUA system under a wide range of futures. In brief, WEAP enables integration of physical hydrologic processes with management of water demands and supplies using a link-and-node representation of a water management system, as constructed by a user. The WEAP model was used primarily to evaluate projected annual urban demands, sources of supply, and unmet demands.

RAND previously developed a WEAP model for the IEUA service area (Groves, Lempert, *et al.*, 2008) based on information available during the 2003-2005 time period. For the present study, RAND developed a new WEAP model based primarily on IEUA's latest spreadsheet-based information about current water supplies and demands, and annual projections of them through 2050. See Appendix 2 for more detail.

Absent available detailed analyses of how climate change could affect each element of IEUA's water supply portfolio, RAND worked with the best available data to develop some coarse approximations of how different supplies and demand would change under different assumptions and projections of climate conditions. These analyses were developed as a first step towards a more comprehensive assessment of IEUA resilience to climate change, and were vetted by IEUA water managers. For the purposes of this initial work, these coarse approximations provided sufficient insights into the potential impacts of climatic changes on supply and demand to facilitate deliberation over the usefulness of different types of water management projects.

Several "simple models" were developed to estimate the impacts of climatic changes on the following elements of the IEUA system (see Appendix 2 for details):

- *Local surface supplies, storm water, and replenishment supplies*: two regression models of historical annual local surface supplies and annual climate were used to estimate future local surface supplies based on projections of temperature and precipitation. These models were applied to estimate local surface supplies, available storm water supplies, and non-MWD replenishment supplies.
- *Groundwater safe yield*: Projections of future safe yield under different trends in climate conditions were developed by Wildermuth Environmental Inc. (WEI) and provided to IEUA and the study team. The current long-term sustainable yield of the groundwater basin was then modified for each climate projection based long-term precipitation trend perturbation factors derived from the WEI analysis.
- *Imported supplies via Metropolitan Water District*: A simple linear model of supply availability over time from Northern California via MWD was used to modify IEUA's contractually available supply from MWD. Two different climate response rates were

evaluated that effectively assumed a 17% and 34% reduction in imported available water by 2040.

- *Water demand*: Demand climate adjustment factors were developed using IEUA calculations of the sensitivity of demand to climate using MWD-MAIN. These factors were used together with the climate scenarios (annual average temperature and precipitation) to adjust the demand annually.

By imbedding these models into the WEAP model, we estimated future local surface water production, groundwater sustainable yield and replenishment, outdoor urban demand, and possible adjustments to water imports under changing climate. This WEAP model was used to both test baseline supply resiliency to climate change as well as determine expected benefits from new water management projects.

Portfolio Development Tool

With inputs from the IEUA and its member agencies, RAND created a Portfolio Development Tool (PDT) using the visualization software platform Tableau. The purpose of this activity was to support Step Two of our analysis by creating a user-friendly interface through which the IEUA and its member agencies could explore a variety of water management projects and develop portfolios that included one or more projects. The PDT enables users to review individual project attributes—both quantitative (i.e., how much water they produce) and qualitative (e.g., whether they contribute to different IEUA regional goals)—and determine how combinations of these projects together would increase future supplies, moderate demand, and meet qualitative, regional goals. IEUA and RAND used the PDT to support a series of meetings between the IEUA and member agencies and a workshop co-run with member agency representatives to create different adaptive, integrative options for increasing future water supplies. The final list of portfolios selected by the IEUA using the PDT is represented in the table below (Table 2), and the IEUA IRP includes more detailed description and rationale for these portfolios.

Table 2: Management portfolios developed using the Portfolio Development Tool

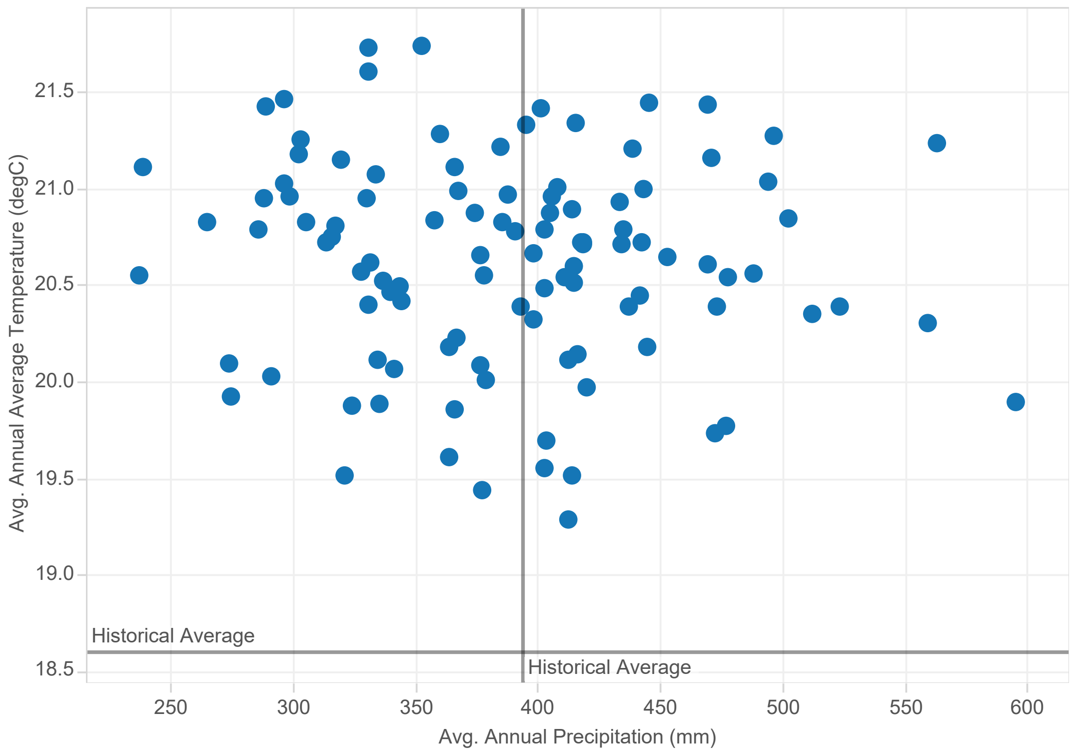
Portfolio Name	Portfolio Description
Portfolio #1	Maximize the Use of Prior Stored Groundwater
Portfolio #2A	Maximize Recycled Water (Including External Supplies) and Local Supply Projects and Implement Minimal Water Efficiency
Portfolio #2B	Portfolio 2A Plus Secure Supplemental Imported Water from MWD and Non-MWD Sources
Portfolio #3A	Maximize Recycled Water (Including External Supplies) and Implement Moderate Water Efficiency
Portfolio #3B	Portfolio 3A Plus Implement High Water Efficiency

Portfolio #4	Maximize Supplemental Water Supplies and Recycled Water Supplies
Portfolio #5A	Maximize the Purchase of Imported Water from MWD and Implement Minimal-Moderate Level of Water Efficiency
Portfolio #5B	Portfolio 5A Plus Maximize Recycled Water

Climate and Demand Futures

The WEAP model was then used to “stress test” the resiliency of the IEUA service area’s baseline water supplies, and baseline supplies plus the different future water management project portfolios, under different conditions of climate change and demand. This is Step Three of our analysis. The study considered the 106 projections of future climate displayed in Figure 1. These were downloaded from an archive of downscaled global climate model simulations, described in Appendix 2. These 106 projections of future climate were integral to our ability to stress test the IEUA water management system in its ability to meet future demand. Each projection represents a plausible climate future in our analysis. Although we cannot know with certainty what type of climatic change the future holds, having a diverse set of projections enables development of management alternatives that could be robust in adapting to a range of different conditions. Figure 2 plots the average annual temperature and precipitation from 2040-2049 for this set of climate projections.

Figure 2: Average annual temperature and precipitation over the Inland Empire Utilities Agency service area from 106 climate projections (2040-2049)



All the climate projections show higher average annual temperatures from 2040 – 2049 than the historical average (1951-1999). This is consistent with observed and projected changes around the world (IPCC, 2014). About half of the climate projections show higher precipitation and half show lower precipitation. Specifically, annual average precipitation varies between 237 mm/year to 595 mm/year, or between 60% and 151% of the historical record. This uncertainty in precipitation trends reflects the difficulty in modeling the complex atmospheric and oceanic processes that govern precipitation patterns in the Southwest United States and the stochasticity of these processes (Peterson *et al.*, 2013). Although these projections do not indicate whether the climate will get drier or wetter in the coming decades in the IEUA service area, they do provide a useful test bed of plausible climate conditions for which to stress test water management plans. Dry conditions can challenge the ability of the system to meet user demand whereas wet conditions can render additional supply investments unnecessary expenditures.

Scientists have confidence that the projections in Figure 2 are suggestive of future climate conditions that are impacted by higher greenhouse gas concentrations in the atmosphere. One reason is that these climate models, when evaluated for historical periods of time (e.g. 1950-2000), estimate past variability that is similar to the observed historical values. To illustrate this, Figure 3 shows the historical, observed annual average temperature and annual total precipitation from 1951 – 1999 for the IEUA service area (blue line on the left), along side the maximum and minimum projected annual average temperature from the 106 climate scenarios for the same time period (box charts on the right). The models, when "backcasting" the same historical time period, estimate a range of maximum and minimum temperatures that are inclusive of the historical observed maximum and minimum temperature. Figure 4 shows the same comparison for annual total precipitation. Once again, the future and historical maxima and minima appear to have some overlap.

Figure 3: Observed historical annual temperature record for the IEUA service area from 1951 – 1999 (left) compared to the distribution of predicted maximum and minimum temperatures across the 106 climate scenarios for the same historical time period (right)

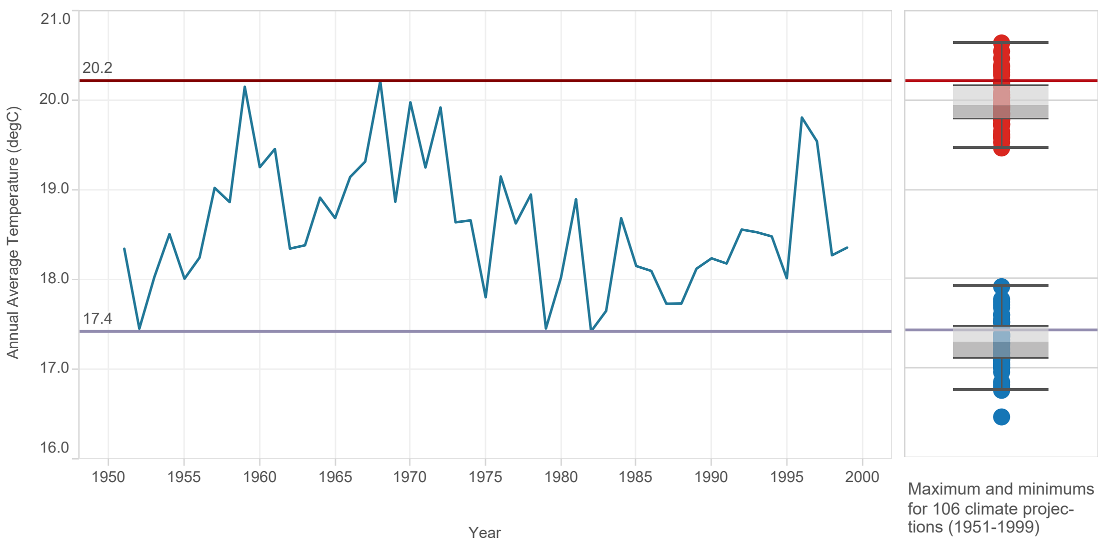


Figure 4: Observed historical annual total precipitation record for the IEUA service area from 1951 – 1999 (left) compared to the distribution of predicted maximum and minimum precipitation across the 106 climate scenarios for the same historical time period (right)

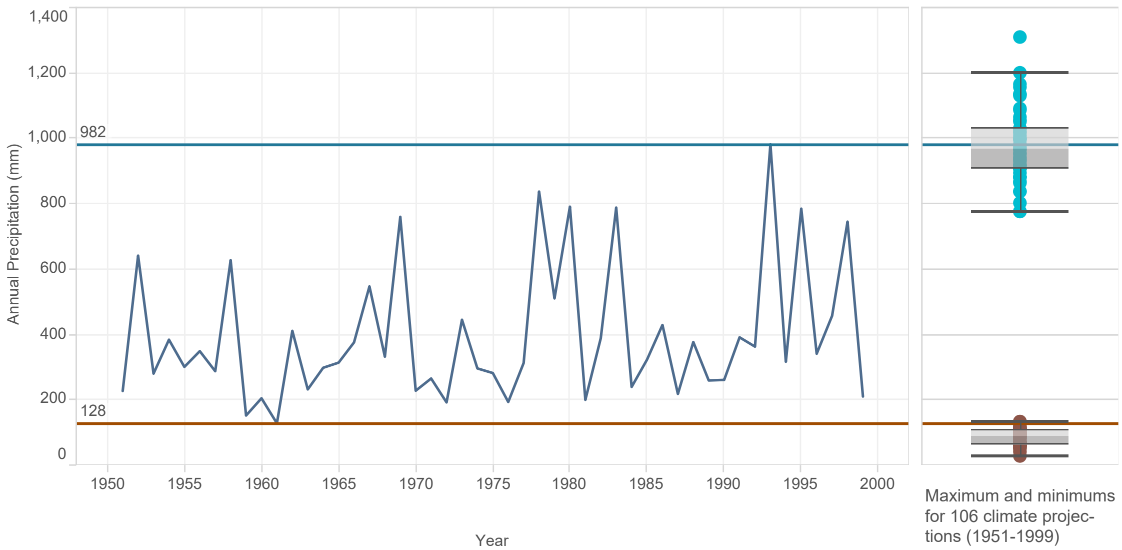
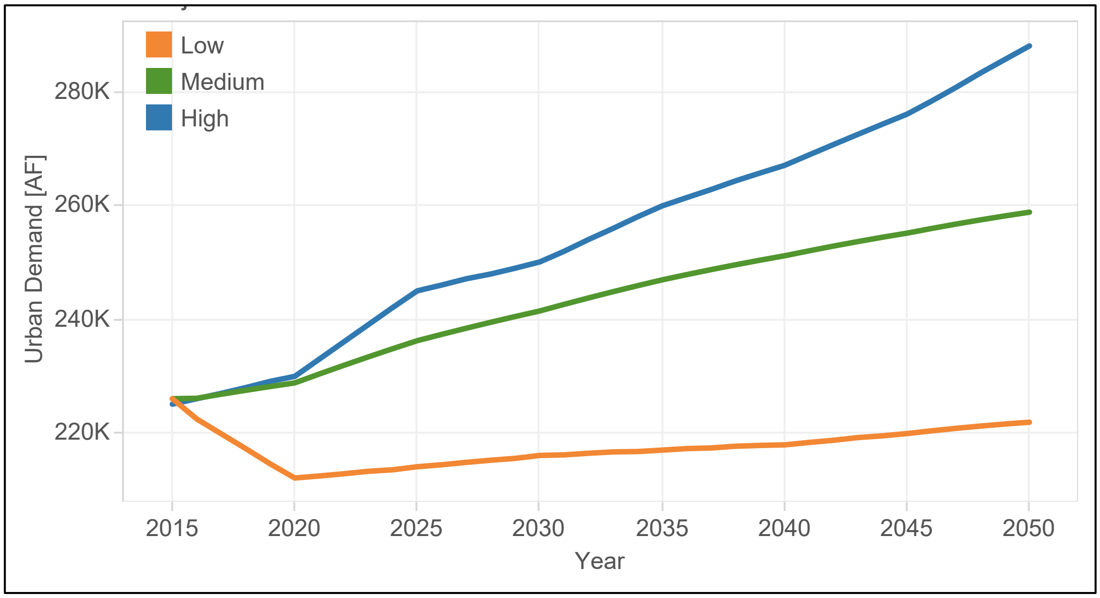


In addition to future climate, this work also examined impact of future demand. IEUA supplied two projections of future demand—a low and high demand estimate. A middle projection was then estimated within the water management model by specifying indoor and outdoor water use rates that were between those used for the high and low demand estimate. Figure 5 shows these three demand scenarios under conditions of no climate change. It also shows unmet demand under historical climate conditions.

Figure 5: IEUA demand scenarios under no climate change



Simulating future conditions

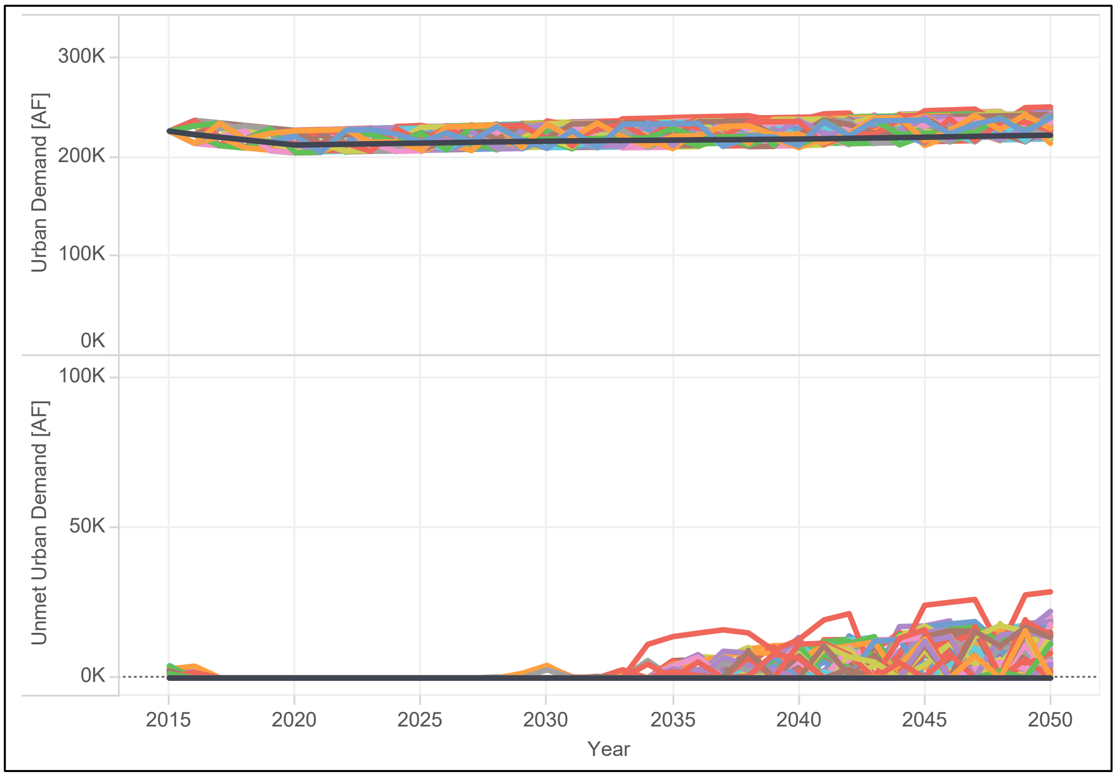
The study team used the WEAP IEUA model to stress test the IEUA's baseline supplies and proposed supply augmentation portfolios, and evaluated urban demand, supplies, and unmet demand from 2015 to 2050 for each of the 106 climate change projections as well as a projection that repeated historical climate conditions. Impacts of these 107 climate futures on IEUA's baseline supplies and proposed portfolios to augment supplies were examined in the context of the three future demand scenarios, as well as assumptions about the strength of climate change on imports, and the sensitivity of local supplies to temperature. In sum, IEUA's baseline supplies and each augmentation portfolio were tested against 1,284 futures (107 climate projections x 3 demand scenarios x 2 regressions to estimate climate impacts on local supplies x 2 levels of climate impact on water imports). The necessary computing capacity was obtained via Amazon Web Service, which enabled the WEAP model to be run hundreds of times simultaneously.

Results

IEUA baseline supplies may be insufficient to meet future demand

We found that, under the low demand scenario, supplies were sufficient under historical climate and mostly sufficient through mid-century with climate change (Figure 6). After 2035, some shortages begin to appear. The figure below shows results that assume the strongest effect of climate on imports, and that temperature changes affect local supplies. See Appendix 2 for more detail.

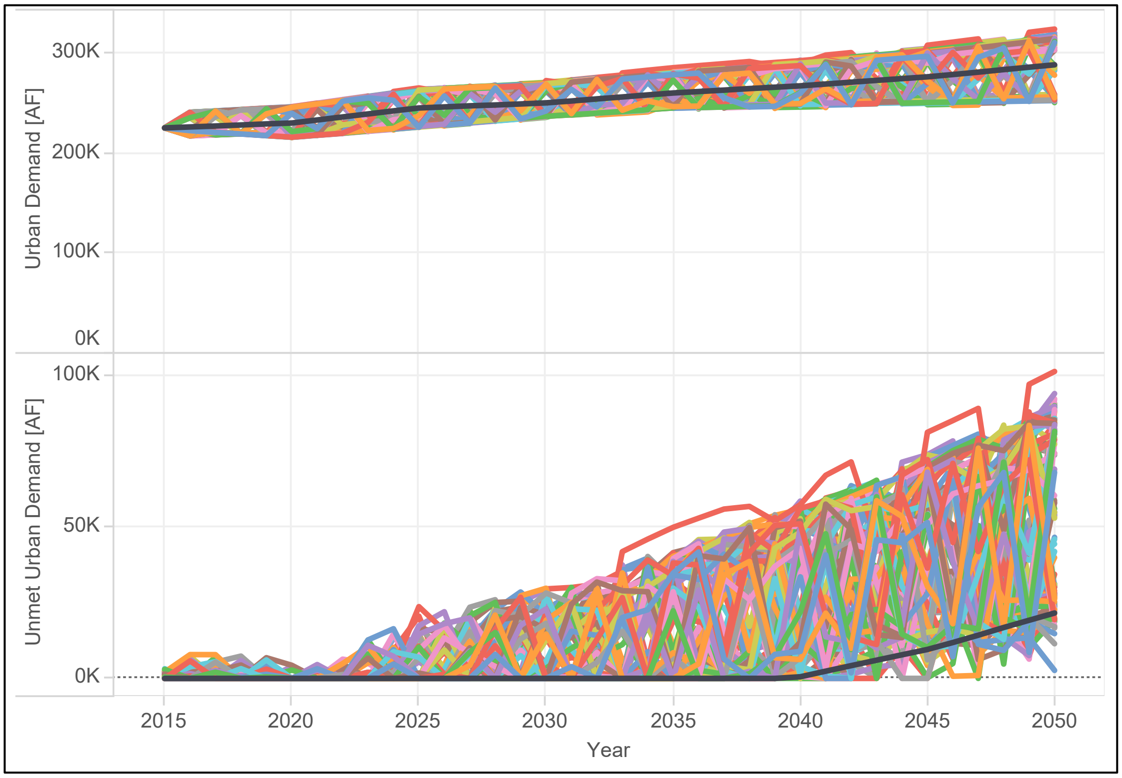
Figure 6: Unmet demand for IEUA service area by climate change scenario over time (low demand scenario)



Note: Colored lines correspond to the individual 106 climate scenarios. The black lines correspond to the historical climate scenario.

However, supplies do not appear sufficient to meet demand in the medium (not shown) and high demand scenarios as early as 2016, with the level of unmet demand ramping up significantly after 2020. Under the high demand scenario, unmet demand is nonzero even under historical climate conditions (Figure 7).

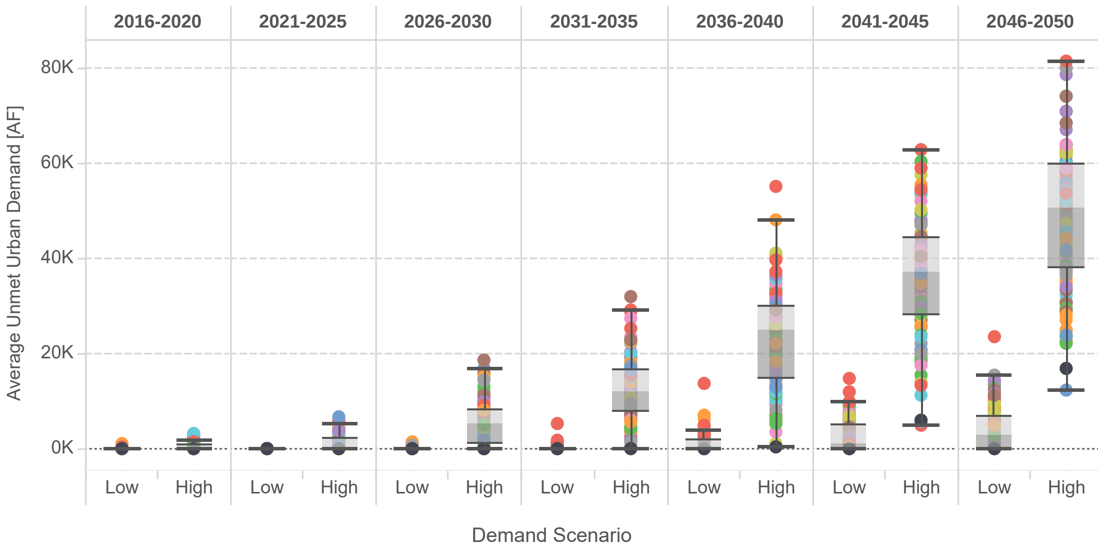
Figure 7: Unmet demand for IEUA service area by climate change scenario over time (high demand scenario)



Note: Colored lines correspond to the individual 106 climate scenarios. The black lines correspond to the historical climate scenario.

Figure 8 summarizes the results shown above by 5-year period. For the 2036-2040 period, which essentially reflects the end of IEUA's IRP timeframe, there is virtually no unmet demand for half of the 106 climate projections under the low demand scenario. In contrast, under the high demand scenario, the median result for unmet demand is about 25 TAF/year, and there is unmet demand in most of the future climates considered. Note that the IEUA IRP reports the 75th percentile unmet demand results as a characterization of the majority of plausible futures. The 75th percentile results are seen in the figure as the top of the shaded boxes.

Figure 8: Summaries of unmet demand across climate scenarios by demand scenario and 5-year period

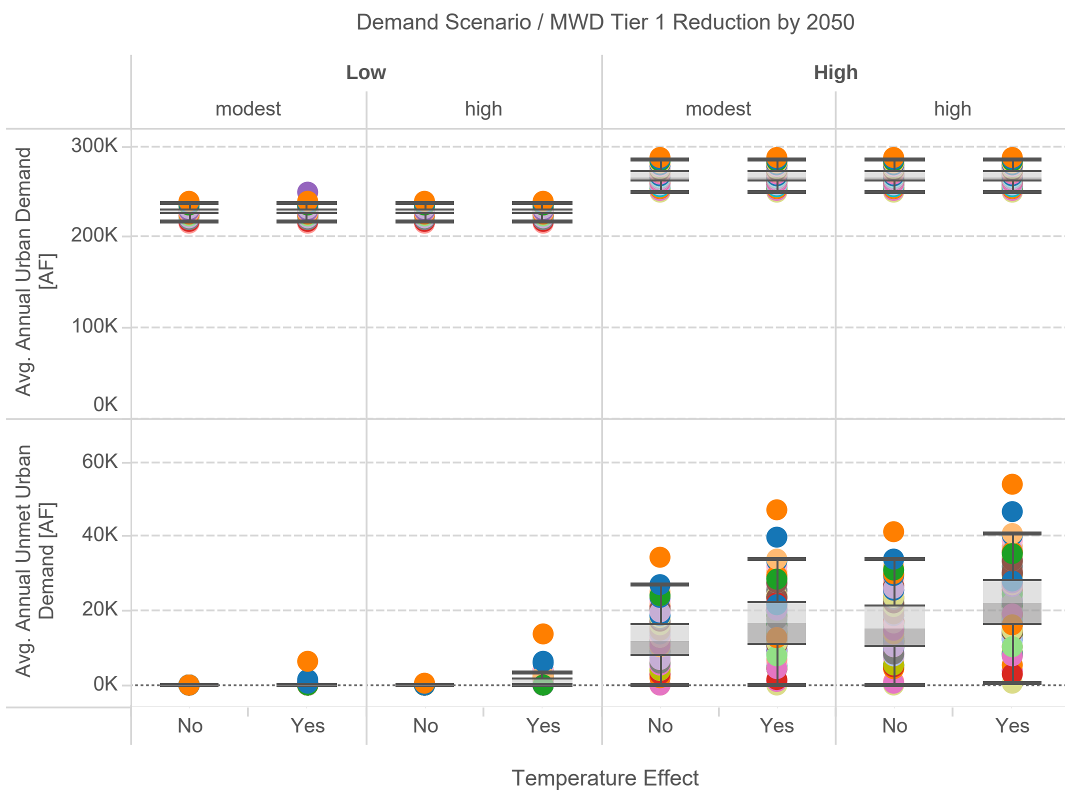


Note: Colored dots correspond to the individual 106 climate scenarios. The black dots correspond to the historical climate scenario. The boxes show the 25th, median, and 75th quartile results, with the vertical stems indicates 1.5 times the 25th-75th quartile range.

RAND also investigated how the results vary with different assumptions about how much MWD supplies might decline over time in response to climate change, and whether or not local supplies, stormwater, and non-MWD replenishment supplies will fluctuate due to temperature in addition to precipitation (see Appendix 2 for more detail). Figure 9 compares the range of unmet demands for the 2036-2040 period under different assumptions about temperature effects on local supplies and climate change on MWD supplies. For the low demand scenario, the assumptions appear to have little effect on the unmet demand results across the climate scenarios. For the high demand scenario, however, there are some modest changes. The effect of going from modest to high climate impact on MWD supplies is about equal to the effect of including the temperature impacts on local, stormwater, and replenishment water supplies. For both types of uncertainties, however, the effects on the results are modest, and are much smaller in scale than differences in results between demand scenarios.

For the IRP, IEUA selected the assumptions that (1) climate change would have a high impact on MWD supplies and that (2) there would be temperature effects on local, stormwater, and replenishment supplies in order to be able to plan for more stressing future situations. These assumptions were made to ensure that IEUA has sufficient resources and necessary infrastructure under a wide range of plausible futures.

Figure 9: Average urban demand and unmet demand (2036-2040) across climate scenarios (boxes), demand scenarios (Low, Wide), climate effects on MWD supplies (modest, high), and temperature effects on local, stormwater, and replenishment supplies (No, Yes)



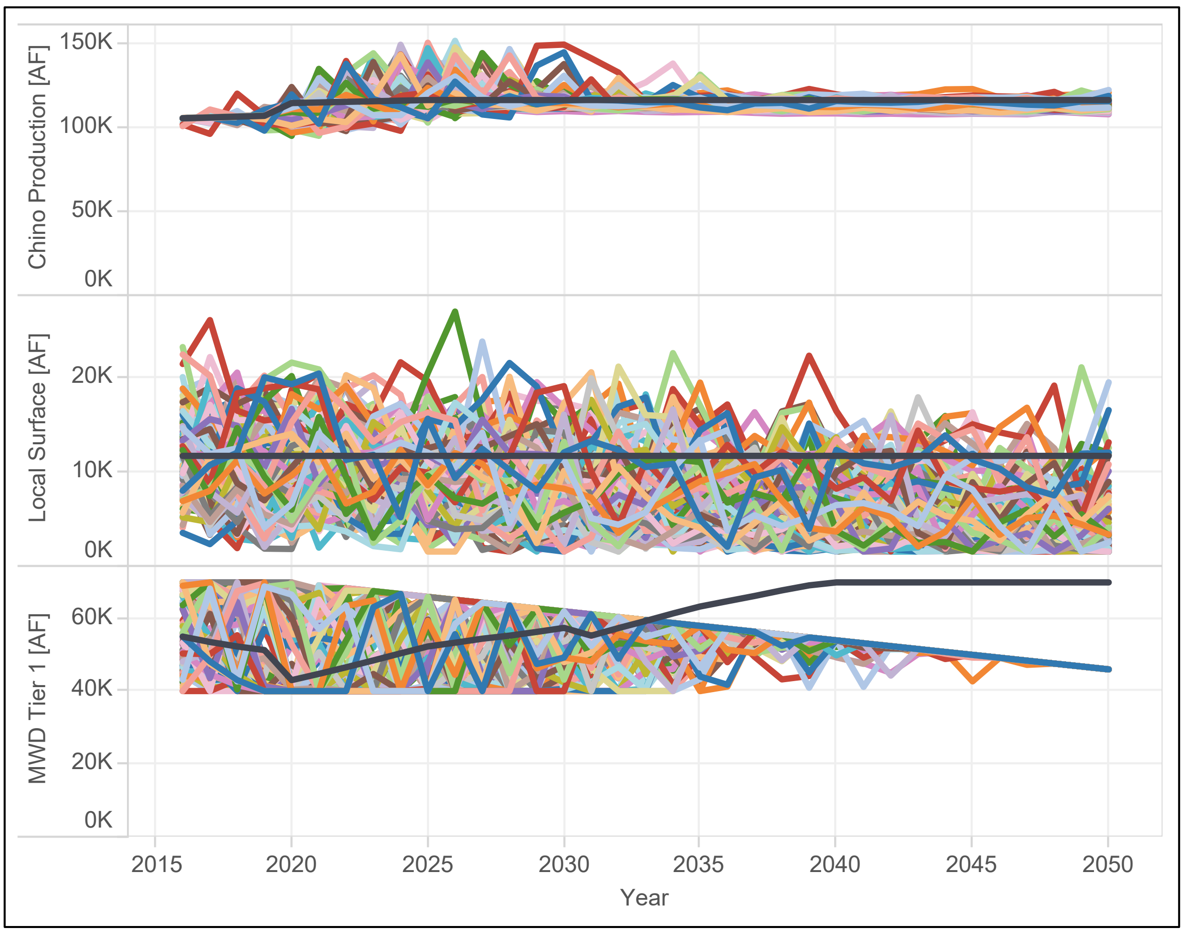
Note: Colored dots correspond to the individual 106 climate scenarios. The black dots correspond to the historical climate scenario. The boxes show the 25th, median, and 75th quartile results, with the vertical stems indicates 1.5 times the 25th-75th quartile range.

Figure 10 shows the major climate-dependent supplies used to meet demand over time for the 107 climate scenarios. The top panel shows these results for Chino Basin groundwater. The figure shows that during the next 15 years, when supplies generally exceed demand, there is a range of groundwater supply use, depending on the demand and availability of cheaper local surface supplies. The increased use during some years reflects deferred use of these supplies during wet years. Around 2030, increasing demand, coupled with declining surface supplies, groundwater supply becomes more stable at the maximum amount available. The slight range of use across the climate scenarios in the out years reflects the different climate effects on safe yield—which is small.

Local supply, some types of which are relatively low-cost (notably excluding recycled and desalted water), fluctuates due to its availability. Figure 10 shows significant variability as well as a tendency for declining amounts of supply, as compared to the typical IEUA assumption of stable supplies based on historical yields (the solid black line). These results reflect the projected warming conditions for all climate scenarios and variability in projected precipitation.

Lastly, the bottom panel of Figure 10 shows use of MWD Tier 1 water over time across the 107 climate scenarios. Future use under assumptions of historical climate declines initially as other supplies are developed. After 2020, however, IEUA increasingly relies on the assumed available MWD Tier 1 supply to meet growing demands. By 2040, all cheaper supplies are completely utilized and MWD Tier 1 supply is used at its maximum level. Note that 2040 is the year in which shortages are also shown to begin (see Figure 7). There is significant interannual variability in the use of MWD Tier 1 supplies across the futures, in response to variable demands and other supplies. In many years, Tier 1 use reaches the maximum available amount. Per the assumptions about climate's impact on available MWD supplies, the maximum amount available begins to decline in 2020. In those years and scenarios in which the MWD Tier 1 use is at this declining maximum level, there is also unmet demand as seen in Figure 7.

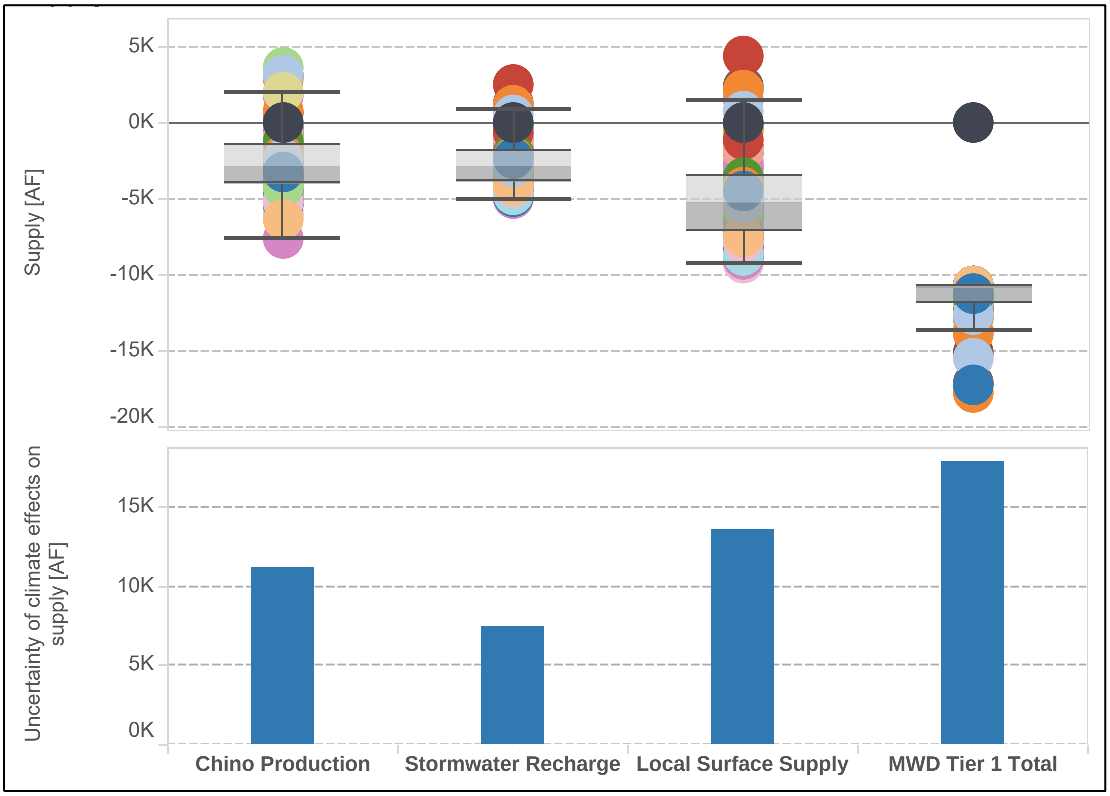
Figure 10: Baseline supply ability to meet IEUA service area in the high demand scenario by climate projection



While there is uncertainty over how climate change might affect IEUA's supplies, the climate scenarios used, combined with assumptions made in this analysis, show a tendency for supply reductions. The top panel of Figure 11 shows that for most scenarios, supplies are lower than they would be under historical climate conditions. The largest potential impact on supply is on MWD imported supply—with all climate scenarios showing a decline in accordance with the assumption that MWD supplies could experience a gradual decline in response to climate change. The second most impacted supply is on local surface supply, with a median decline of about 5 TAF/year. The overall effect on groundwater production is small, consistent with the assumptions about climate's effect on safe yield.

The bottom panel of Figure 11 shows the range in use of future supplies across the climate scenarios. For the resources that are utilized fully due to their lower cost, such as Chino groundwater and local surface supplies, the variability reflects the range of climate impacts on these supplies. For these, the larger range of uncertainty is seen in the local supplies. The range in uses of MWD Tier 1, however, reflects the range of availability of the less expensive supplies—not any assumptions of climate effects on MWD supplies. As described above, the only climate effect on MWD Tier 1 availability is specified through a steady decline in supply availability.

Figure 11: Impacts of climate on IEUA supplies across climate futures (colored dots) (2036-2040) (top) and uncertainty in the magnitude of climate impacts uncertainty (bottom)



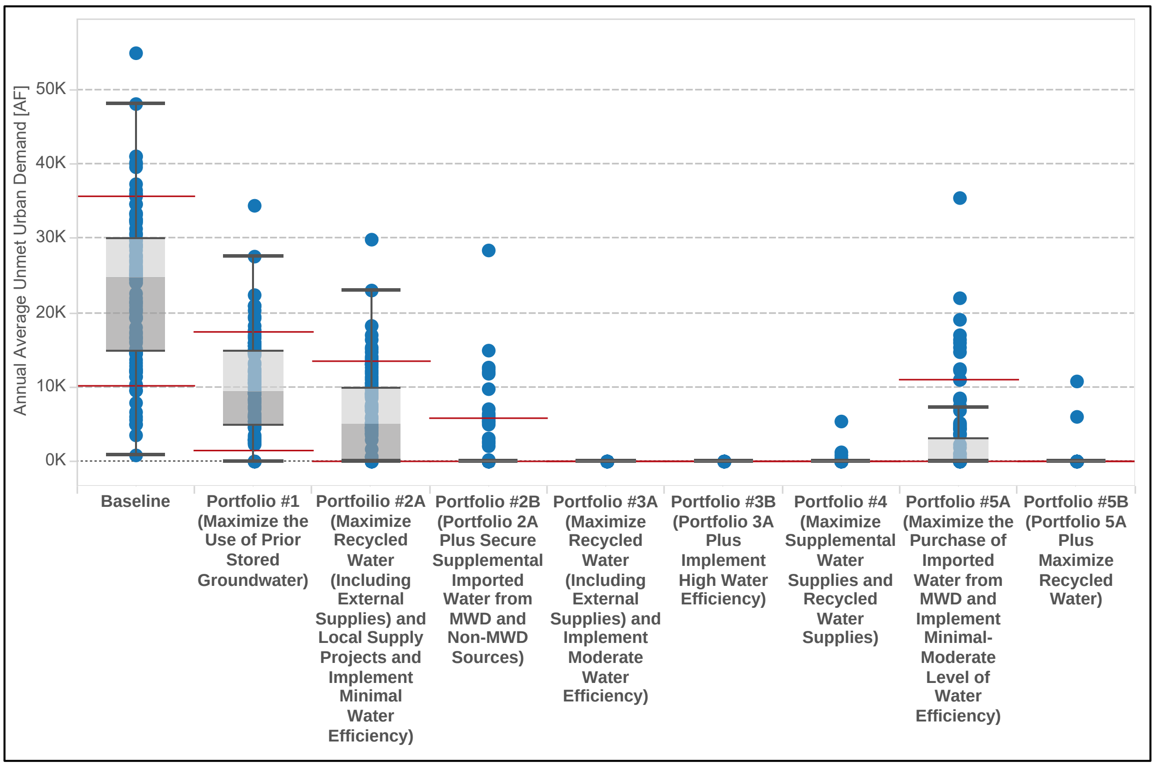
Note: Colored dots correspond to the individual 106 climate scenarios. The black dots correspond to the historical climate scenario. The boxes show the 25th, median, and 75th quartile results, with the vertical stems indicates 1.5 times the 25th-75th quartile range. The blue bars indicate the range of supply outcomes across the climate scenarios (excluding the historical simulation shown by the black dot).

Management strategies that focus on efficiency and maximizing use of recycled and imported water help close future gaps between supply and demand

Through interactions with member agencies and other stakeholders, the IEUA developed the seven portfolios discussed above in Table 2, consisting of different water management actions aimed at closing the future gap between supply and demand, and meeting other qualitative regional goals.

Using the WEAP model and the same climate projections used to "stress test" the IEUA baseline water supplies, we evaluated how well each of the seven strategies would meet demand in the future. Figure 12 summarizes the performance of the baseline strategy and the seven portfolios in terms on unmet demand from 2036-2040. All portfolios lead to an improvement in unmet demand over the baseline supply. Portfolio 1, which uses previously stored groundwater, reduces unmet demand by more than half for the median climate scenario. Portfolio #2A, which increases use of recycled water and external supplies as well as implements additional efficiency, eliminates unmet demand for more than 25% of scenarios and reduces the median unmet demand to below 10 TAF. Portfolio #2B improves upon portfolio #2A by adding additional imports—all but eliminating unmet demand. Portfolio #5A combines moderate efficiency with increased imports to eliminate unmet demand in more than half of the scenarios. Lastly, four portfolios—#3A, #3B, #4, and #5B—eliminate unmet demand in at least 90% of the scenarios. The first two do so by significantly increasing efficiency—effectively ensuring that demand follow the low growth demand trajectory. The other two (#3B and #5B) improve performance by maximizing recycled water use while also increasing imported water supplies.

Figure 12: Average unmet demand (2036-2040) across climates projections for high demand projection and different IEUA portfolios



Conclusion

This is one of a growing number of water planning examples that highlights the benefits of examining the impacts of different climate change futures on meeting consumer demand. Here, assumptions about demand growth and climate future both had substantial impacts on ability to meet demand, and level of climate change impact on imported water as well as temperature impacts on local supplies also had some effect, especially in the most stressing demand future. Using these results, RAND and IEUA were able to identify types of management strategies focused on efficiency and maximizing available supplies that helped close the modeled future gaps between supply and demand. This work also demonstrates the value of visualization tools and water management simulations that can help facilitate discussion of alternatives for managing water resources in a very uncertain future.

For IEUA, participating in this process was not academic. As reported by IEUA management, it was a “game changer”. This is because the analytic process described herein enabled understanding of how powerful water use efficiency and local supplies are in reducing the risk of future supply shortfalls in IEUA’s service area, and also provided reassurance that their region is prepared for a future with uncertain shifts in climate. By engaging in this process, IEUA has not only identified how and when changes in temperature and precipitation could impact its water supplies, but also how demand influences the delicate balance between supply and demand. Both the timing of surges in unmet demand and the types of management actions that could help mitigate anticipated gaps in supply are helping to inform the construction of the IRP in a way that encourages adaptation and the use of integrative plans. Future work could investigate more specifically which assumptions related to future climate, demand, and supply lead to the greatest challenges in unmet demand, which could further help IEUA refine management practices and future plans.

Appendix 1 – Portfolio Development Tool

This appendix describes the IEUA Portfolio Development Tool (PDT) developed by RAND (Figure 13), with input from IEUA on its function, design, and input data. The PDT is a decision support tool designed to help IEUA and its member agencies assemble different portfolios of water management options that could help ensure the IEUA meets future water demands. IEUA used the PDT to develop a set of portfolios that were then evaluated across different climate and demand scenarios using a water management model described in Appendix 2. Although the information within and specific design of the PDT are specific to IEUA's needs, the visualization platform and methodological process could be used in the context of any water agency with similar needs for long-range planning under uncertain future conditions.

Figure 13: Title screen for the Portfolio Development Tool

The PDT was developed using Tableau—a business analytics and visualization software package. All the data used to develop the PDT were provided to RAND by IEUA, and the PDT was deployed via the Internet for IEUA and stakeholders. In the series of figures below, we walk through each of the PDT's visualizations. Once again, the design and data shown here are specific to IEUA, but this type of tool could be configured to support decision-making within numerous types of organizations.

Overview of the Portfolio Development Tool

The PDT’s main function is to help the user develop a portfolio of management options that meets specified near-term and long-term water supply and demand targets. To do this, the user first specifies the projects that he or she wishes to consider. Next, the user specifies the near-term and long-term targets. The PDT then identifies the projects that would best achieve the targets from the set of eligible projects using a cost effectiveness criterion. In this context cost effectiveness is expressed in terms of levelized cost—or average cost per unit of new supply or demand reduction. Lastly, the PDT summarizes the included projects, their overall attributes, their cumulative yields, and their cumulative costs.

Portfolio Development Tool Visualizations

Figure 14 shows one visualization used to concisely display qualitative information about the attributes of different water management projects. Here, each row pertains to a different project, organized by type, with each column indicating one of 16 qualitative attributes related to IEUA’s future goals (e.g., increasing water levels in critical groundwater management zones, increasing stormwater capture and associated groundwater recharge). Filled circles indicate that projects help meet certain goals, half circles indicate that a projects have no impact on goals, and open circles indicate that projects detract from efforts to meet goals. This visualization provided a reference for IEUA and member agencies used this tab to contrast how well different types of and individual projects helped meet goals.

Figure 14: Summary of how a sample of IEUA potential projects would help meet qualitative goals

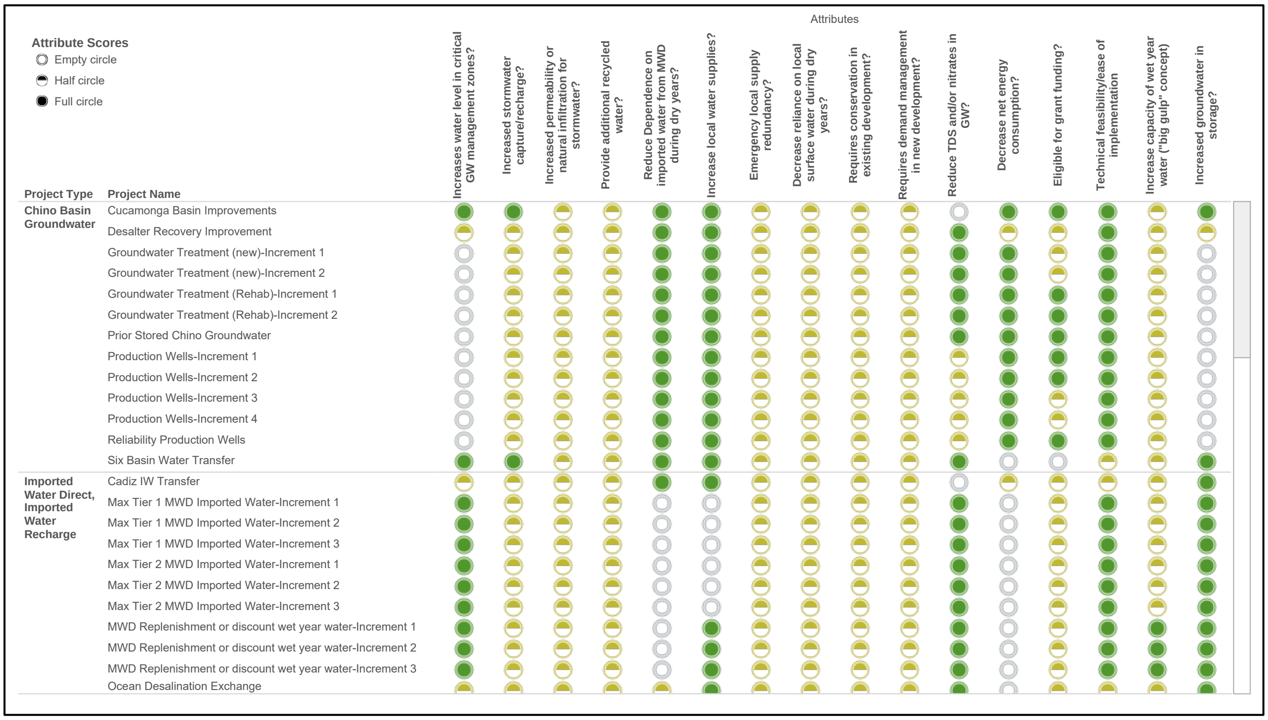


Figure 15 displays the same IEUA qualitative goals as in the previous screenshot (above), but summarizes their values within the different project categories. This shows, for example, how many projects within the more general category of "Chino Basin Groundwater" add to, detract from, or have neutral effects on different goals. This assists decision makers in identifying which categories have the most projects that might contribute to the achievement of particular goals.

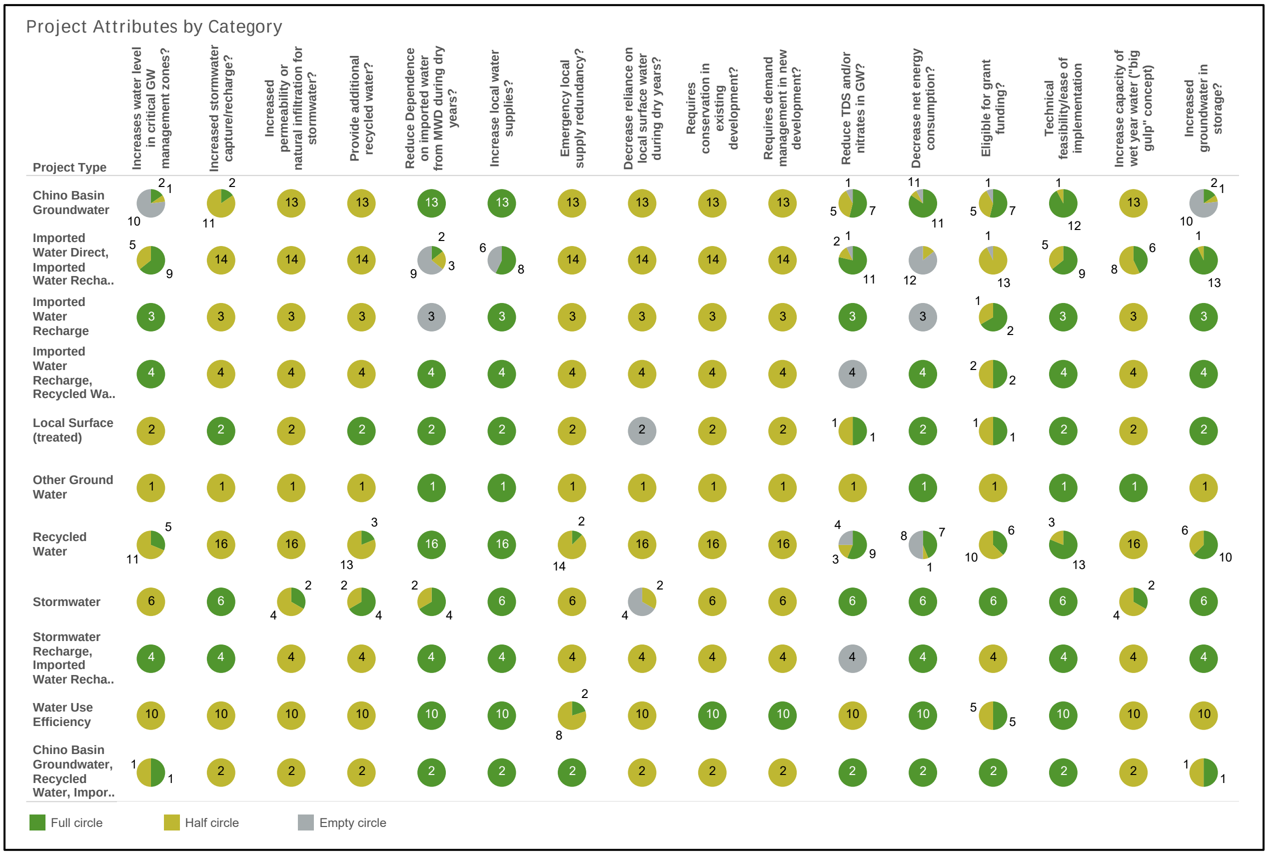
Figure 15: Summary of how well projects in different categories meet various IEUA qualitative goals

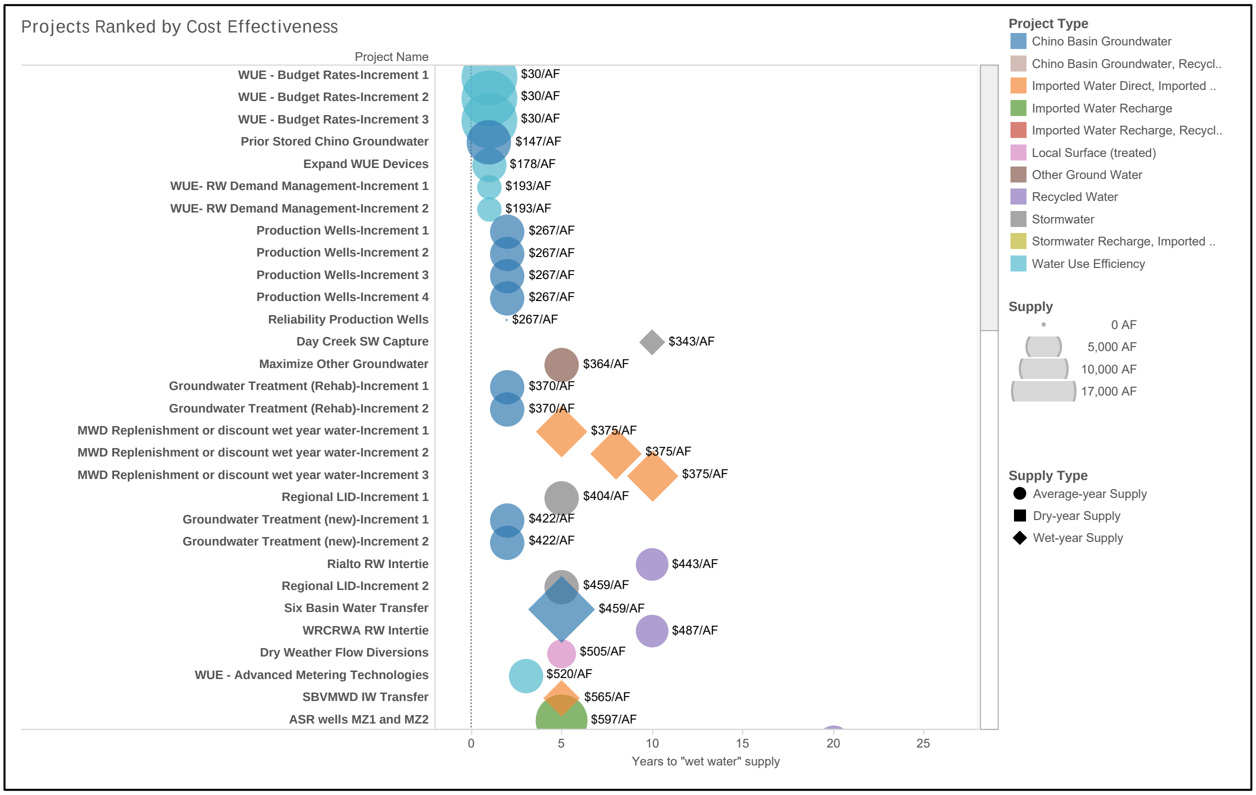


IEUA has considerable supplies to meet current and future needs already. These are highlighted in the top panel of Figure 16, and include groundwater, recycled water, imported water, conservation measures, and other sources. The color bars indicate when these sources come online, and most are already available. (Note that those that come online in the future are already planned for implementation and are thus not considered in the portfolio options directly.) IEUA and member agencies requested this view of the baseline supplies because it serves as a useful perspective upon which to layer projects to bring additional future supplies. Below the baseline supply panel are the different potential projects, sorted by general categories, and with information about cost and amount of supply each is estimated to provide. Note that not all projects are visible in this screen shot.

Figure 16: Summary of baseline supplies, estimated new project supply amounts, and new project costs

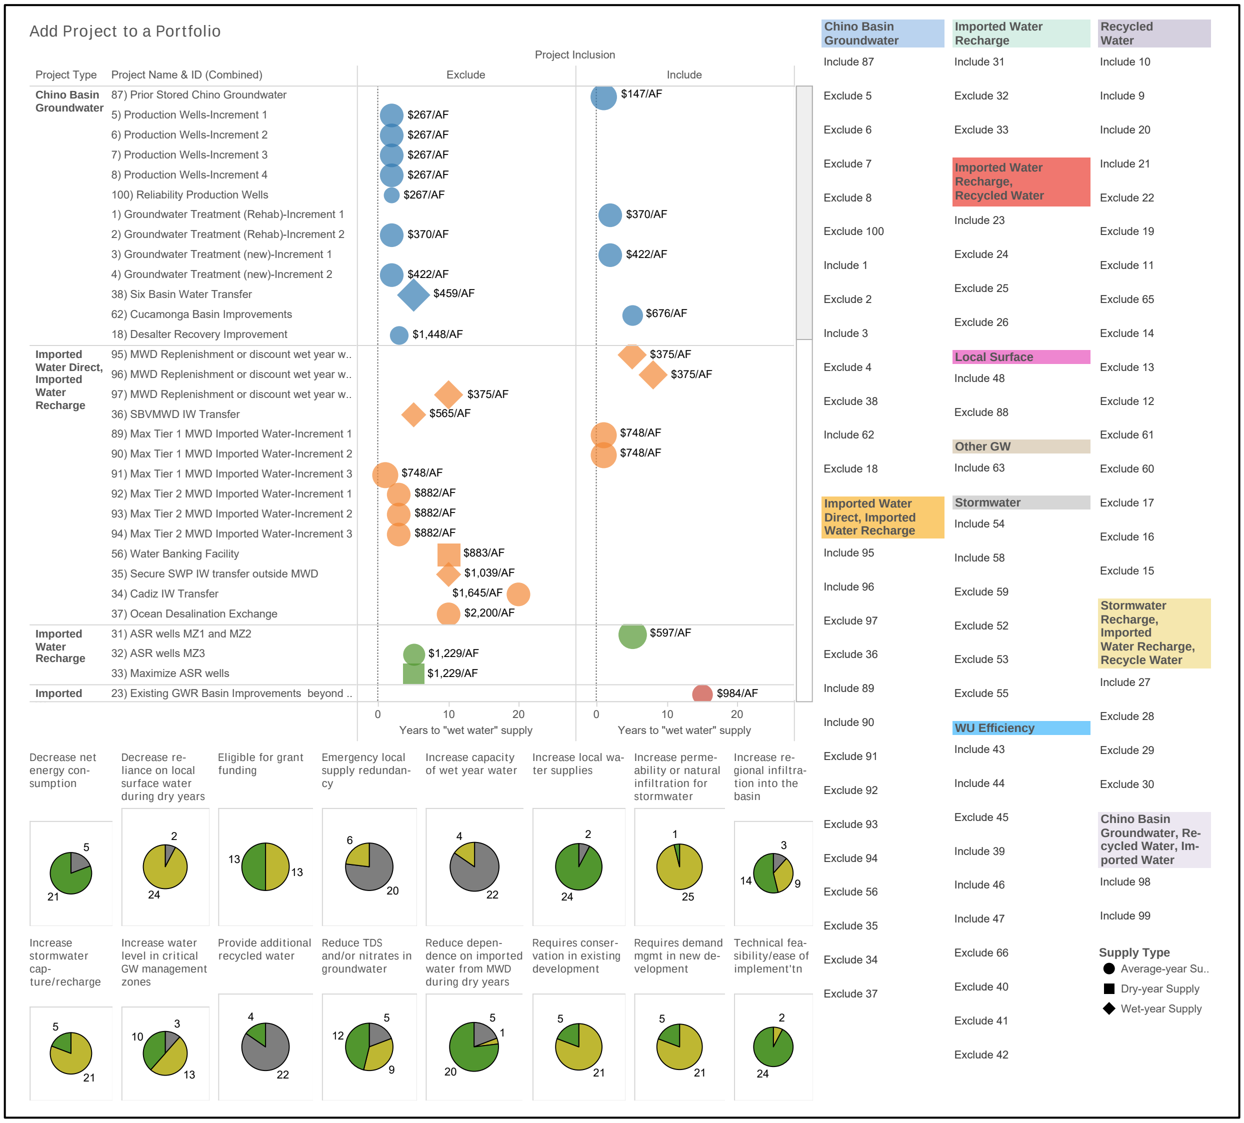
Figure 17 displays all the projects, sorted by preliminary estimates of per unit water cost (these have yet to be finalized). Symbol coloring indicates its category, size indicates its estimated volume; horizontal position indicates the number of years until which the project produces enough water to add to the supply IEUA distributes to stakeholders; the text label indicates its cost; and its symbol indicates whether the water is available during any given year or only under particularly wet or dry conditions. This view was useful for stakeholders to compare projects, and general categories of projects, by supply amount, timing, and cost.

Figure 17: Project cost per acre-foot, with information on project type, supply amount, supply type, and number of years to "wet water" supply



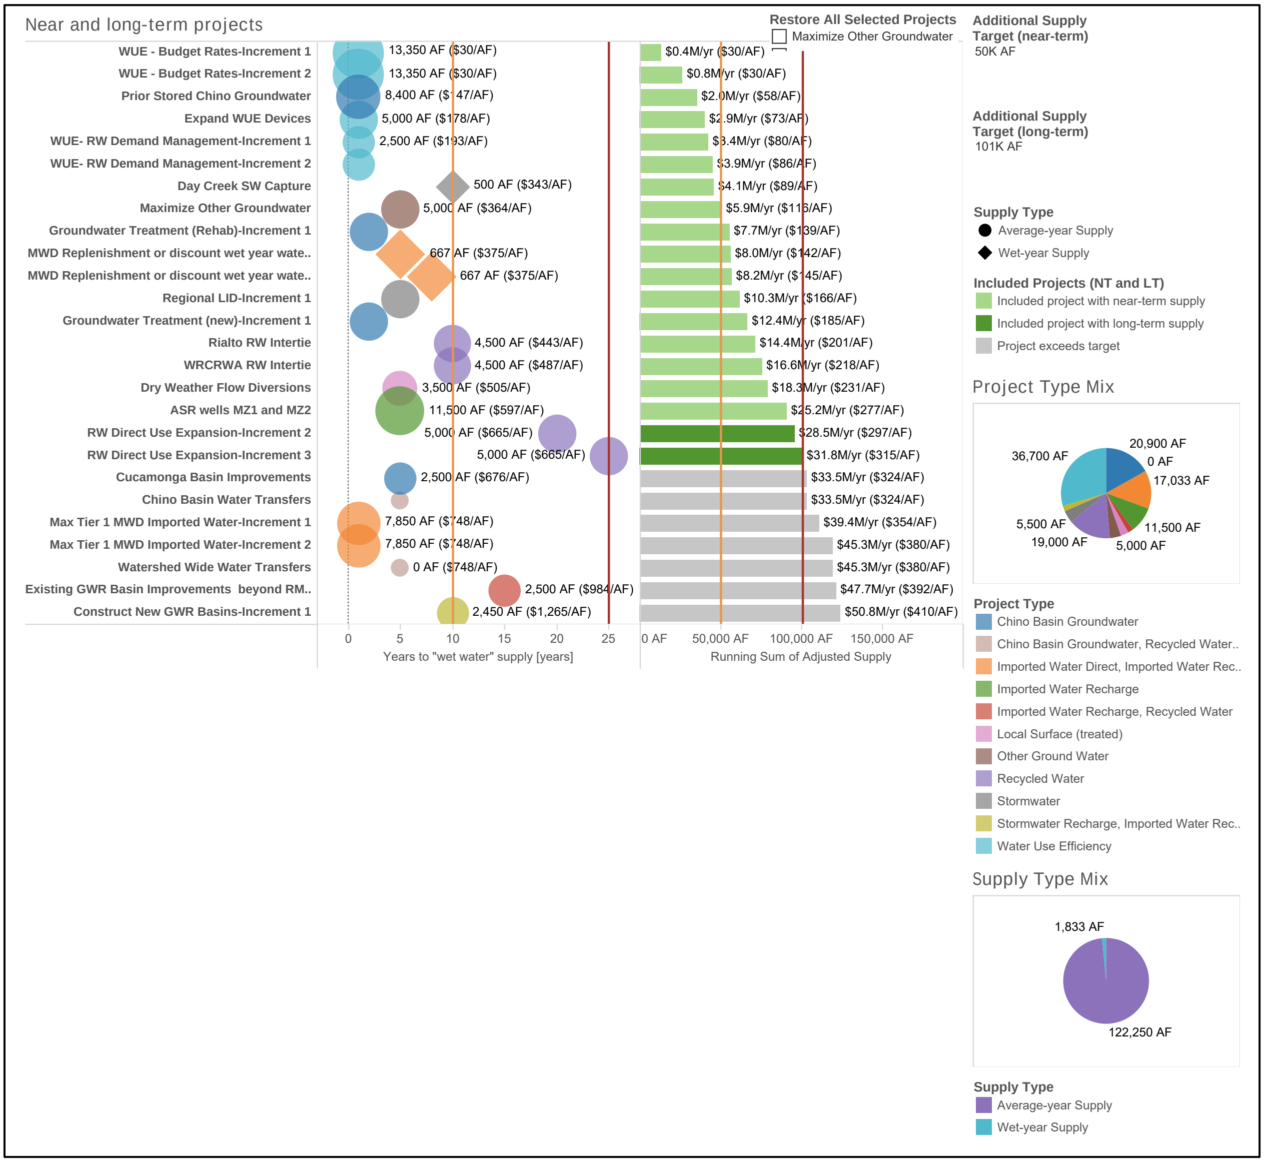
The next figures show how IEUA and member agencies were able to use the tool to create different potential portfolios of water management options. Figure 18 shows a tab in which the user is able to select individual projects to be considered in a portfolio. The user can exclude or include a project with a single click of the toggles on the right side of the screen shot. Projects' inclusion, category, cost, and years to wet water supply are tracked in real time on the left side of the screen. Aggregate summaries of the project attribute measures are shown as pie charts at the bottom of the screen. In this figure, a subset of projects is selected for inclusion, and only some projects are shown in the figure. In the tool, the user is able to scroll to see projects from all project categories.

Figure 18: Portfolio building tab enabling user to include and exclude specific projects in real time and visually track different project categories, costs, and years to "wet water" supply



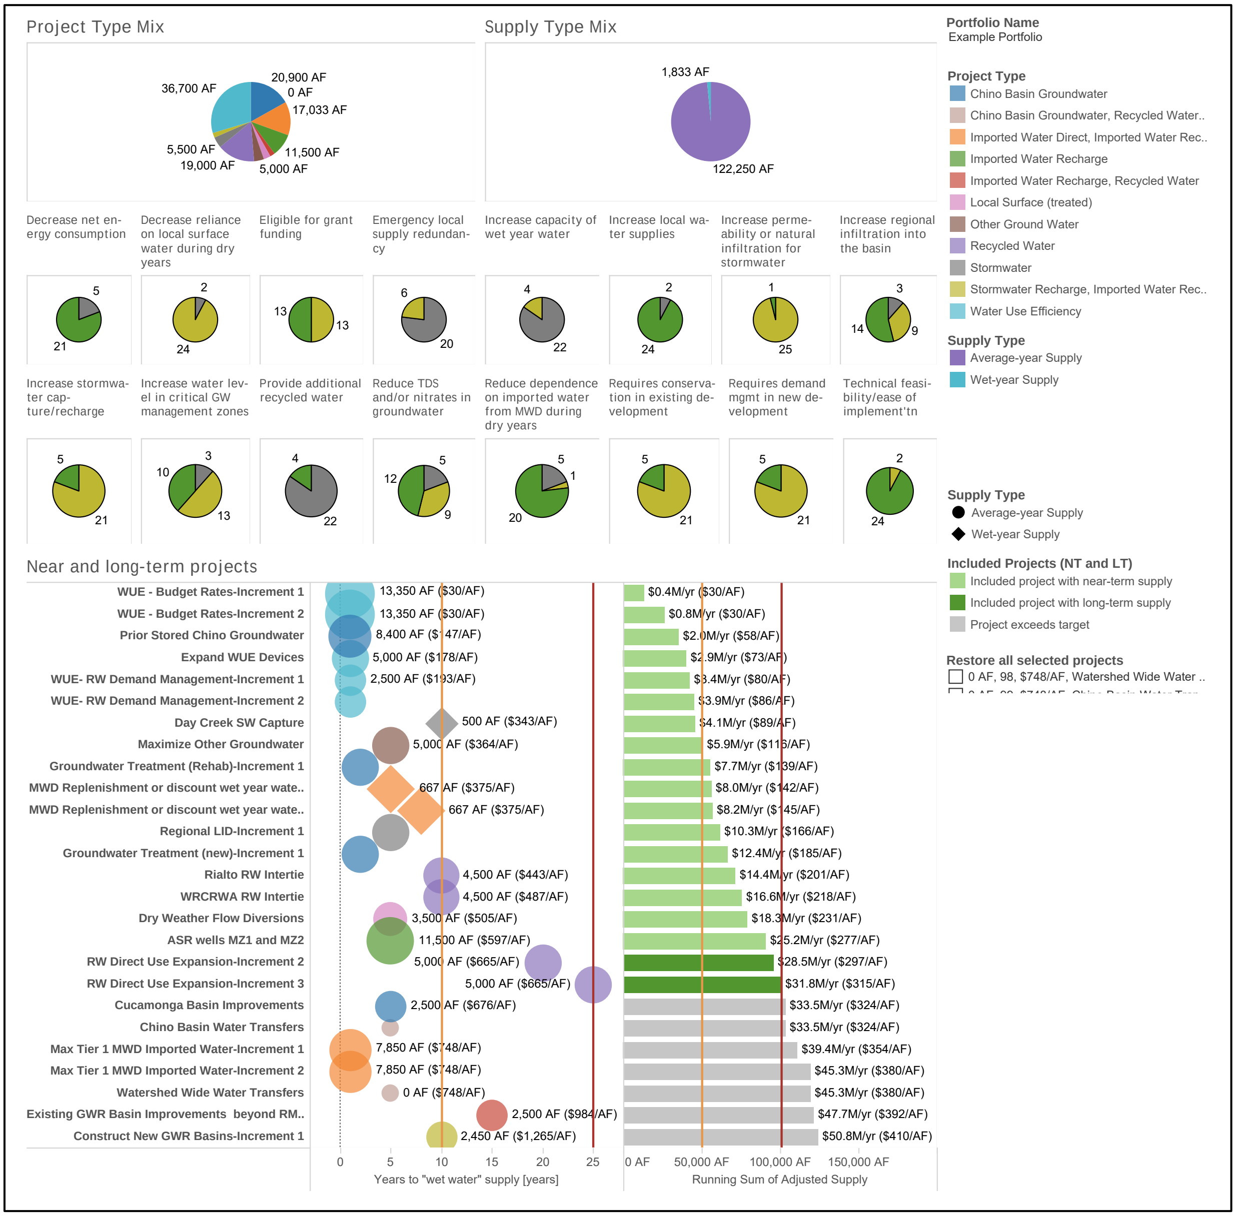
The next visualization (Figure 19) takes the options included in the previous screens and sorts them by cost effectiveness and availability to meet user-specified near-term (year 10) and long-term (year 25) targets. In this example, the near-term target is set to 50 TAF, whereas the long-term target is set to 101 TAF. On the left, projects are shown ordered by cost effectiveness. The bar chart to the right shows the cumulative new supply or demand reduction. Projects that meet the near-term or long-term targets are shaded green, indicating that they are included in the final portfolio. The project shaded dark green are only available to meet long-term demand. On the right, a pie chart summarizes the mixture of projects used to meet the supply targets and the type of projects with respect to availability (all year, wet year, or dry year).

Figure 19: Example portfolio with information on projects included therein, and how well projects meet supply goals



Lastly, Figure 20 provides another summary of the defined portfolio. This includes a summary of the supply and project category information in Figure 19, but also displays summaries of the project attributes—suggesting how well a particular portfolio meets different IEUA qualitative goals. IEUA and member agencies were able to use this display as a final summary chart for each portfolio they explored.

Figure 20: Example project portfolio summary, including how well projects meet IEUA qualitative goals



Appendix 2 – Water Management Model And Assumptions

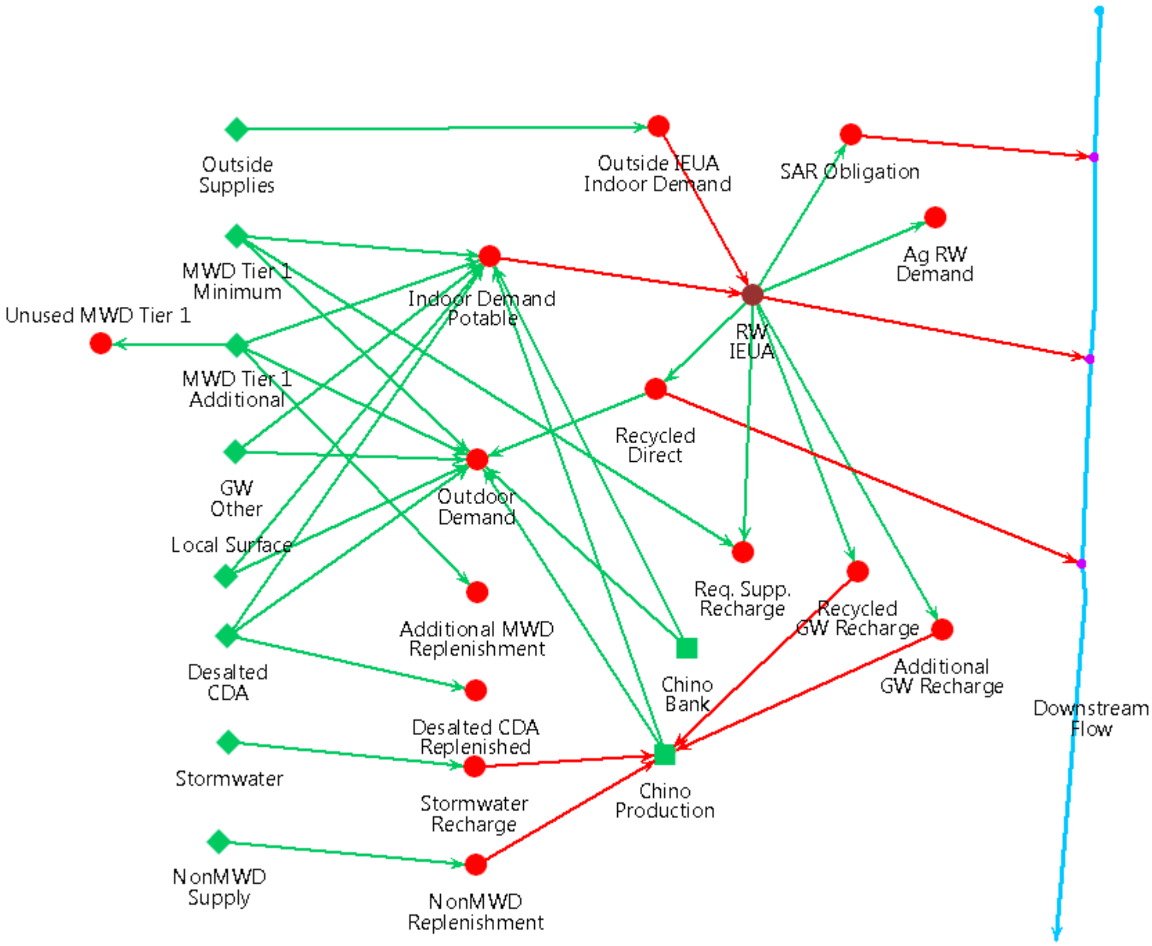
Model Overview

The study team built a model of the IEUA water management system, based on tabular monthly and annual information on historical and projected IEUA water supplies and demands provided by IEUA. The model includes simple relationships and data on estimated future climate conditions to evaluate water supply and demand balance conditions under alternative futures. Lastly, the model evaluates how different water management portfolios, developed using the Portfolio Development Tool (see Appendix 1), would improve performance over these futures.

The model is built in the Water Evaluation And Planning (WEAP) system, developed by the Stockholm Environment Institute (SEI) (Yates *et al.*, 2005). The WEAP IEUA water management model represents the IEUA system through a set of arcs and nodes. Nodes represent locations of water inflows, storage (surface or groundwater), outflows, or demand. Arcs represent conveyance, either natural or constructed, between different nodes.

The IEUA WEAP model calculates how water demand would be met by various supplies based on a system of supply preferences and priorities for each demand node. The model schematic shows the connectivity of water flows among the nodes via the arcs within the model (Figure 21). The schematic is not intended to represent the specific locations of IEUA system elements, but rather show their connectivity. Table 3 lists and describes the demand and supply nodes shown in the model schematic. More details on select demands and supplies are provided in the sections below.

Figure 21: Schematic of the WEAP model of the Inland Empire Utilities Agency service area



Note: RW = recycled water; Ag = agricultural; SAR = Santa Ana River; MWD = Metropolitan Water District of Southern California; CDA = Chino Desalter Authority; GW = Groundwater.

Table 3: IEUA WEAP model supply and demands

Node Name	Description
Demand	
Indoor Demand Potable	Indoor demand for potable (non recycled) water
Outdoor Demand	Outdoor demand for potable and recycled water
Recycled Direct	Total recycled water demand for outdoor use; met demand passes through to Outdoor Demand node or downstream flow if unneeded
Recycled GW Recharge	Demand for groundwater replenishment water; passes to Chino Production node
Additional GW Recharge	Demand for additional groundwater replenishment as specified by water management strategies; passes to Chino Production node
Outside IEUA Indoor Demand	Demand for water outside IEUA that is provided to IEUA for recycling via RW IEUA node

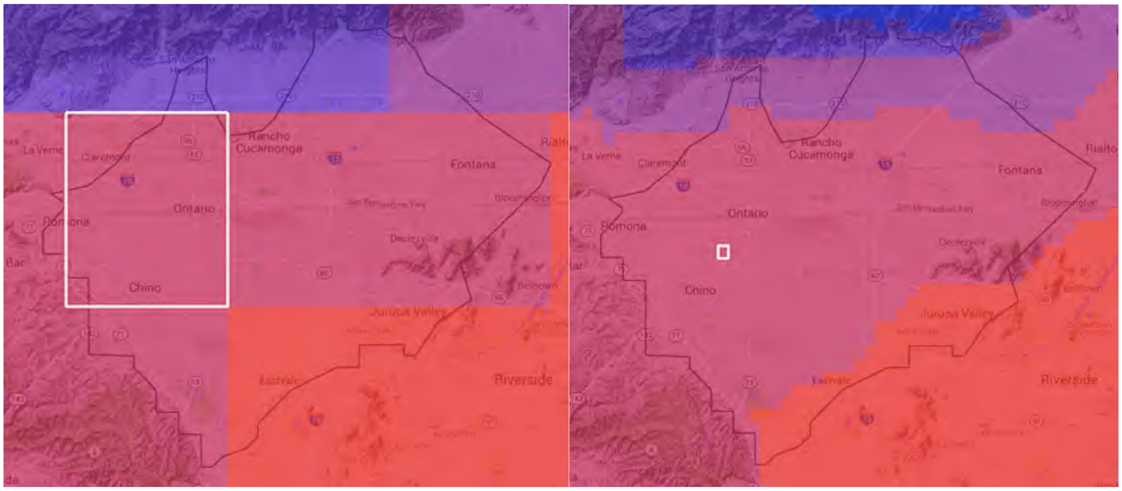
SAR Obligation	Santa Ana River flow obligation; met by recycled water
Ag RW Demand	Agricultural water demand in IEUA service area met with recycled water
Supplies	
MWD Tier 1 Minimum	Specified annual minimum Tier 1 MWD imports (about 40 TAF)
MWD Tier 1 Additional	Additional annual Tier 1 MWD imports, constrained by contract with MWD
Local Surface	Water supplies obtained from watersheds within the IEUA boundary
Desalted CDA	Desalted brackish groundwater from the Chino Desalter Authority facilities
Chino Production	Groundwater from the Chino Basins
GW Other	Groundwater from sources outside the Chino Basin
Stormwater	Additional runoff from storms captured and treated for use
NonMWD Supply	External sources of water used for groundwater replenishment

Climate Scenarios

The study uses downscaled climate data from general circulation models as the basis for a wide range of plausible future climate conditions. Historical and projected climate data from the World Climate Research Programme's (WCRP's) Coupled Model Intercomparison Project phase 3 (CMIP3) multi-model dataset were downloaded from the Downscaled CMIP3 and CMIP5 Climate and Hydrology Projections archive (Maurer *et al.*, 2007).[2] Climate data retrieved from this archive included bias-corrected statistically downscaled (BCSD) global climate model (GMD) monthly mean temperature and total precipitation observations and projections for 36 CMIP3 simulations and 70 CMIP5 model runs for years 1950-2050 (Brekke *et al.*, 2013). Note, however, that observed BCSD data were available only for years 1950-1999. These gridded climate data represented the gridded area bounded by latitudes 34.0N and 34.125N and longitudes 117.625W and 117.5W, roughly centered at Ontario International Airport (Figure 22).

[2] Data is available online at: http://gdo-dcp.ucllnl.org/downscaled_cmip_projections/.

Figure 22: Geographic scale of climate sources for CMIP-3 data (left) and CMIP-5 date (right)



Select Demands

Indoor Potable

Indoor potable demand is calculated as the population within the IEUA service area times an annual water use rate. IEUA, assisted by A&N Technical Services, specified the high and low demand scenario by varying annual water use rates. The middle demand scenario is user definable by setting the indoor and water use rates for 2050. Indoor potable demand does not vary by climate.

Table 4: Indoor potable demand parameters for historical data and scenario projections

Model Parameter	2010 (data)	2014 (data)	2020 (projection)	2050 (projection)
Population (people)	813,695	847,587	896,533	1,249,091 (all)
Water Use rates (gal/person/year)	26,061	23,981	24,090 (high) 22,959 (low)	24,017 (high) 17,082 (low)
Water Use/Demand (taf/year)	65.1	62.4	66.3 (high) 63.2 (low)	92.1 (high) 65.5 (low)

Outdoor

Outdoor demand is calculated as the population within the IEUA service area times an annual water use rate. IEUA, assisted by A&N Technical Services, specified the high and low demand scenario by varying annual water use rates. The middle demand scenario is user definable by setting the nominal outdoor and water use rates for 2050.

IEUA performed a series of sensitivity analyses of urban outdoor demand and weather conditions. By 2040, IEUA estimated that one dry year would increase demand by 5.6%. Similarly, a one wet year would decrease outdoor demand by 5.6%. A longer period of dry weather (3-years) would increase demand by 8.9%. Separately IEUA estimated the long-term effect of warming on outdoor demand. They found that for each degree temperature increase (in Celsius), outdoor demand would increase by 3%. Together these factors were applied to the climate scenarios to estimate how outdoor demand could change due to weather in the future.

Outdoor demand varies by three outdoor water demand factors that are applied depending up the projected precipitation difference from historical (or perturbation), as shown in Table 5. The outdoor water demand factors were derived from IEUA analysis.

Table 5: Climate effect factors on outdoor water demand

Precipitation Condition	Perturbation Threshold	Outdoor Water Demand Factor
Very dry	-5 cm/year	-0.089
Dry	0 cm/year	-0.056
Wet	+ 25 cm/year	+0.56

Agricultural recycled water demand

Agricultural recycled water demand is specified based on IEUA projections and does not vary by climate. This demand declines from about 10,000 AF in 2015 to 2,000 AF by 2025 and then remains constant through 2050. This is due to the transition of agricultural land to urban use.

SAR Obligations

IEUA's Santa Ana River (SAR) obligations are specified to be 17,000 AF/year per IEUA agreement.

Select Supplies

Local Surface supplies

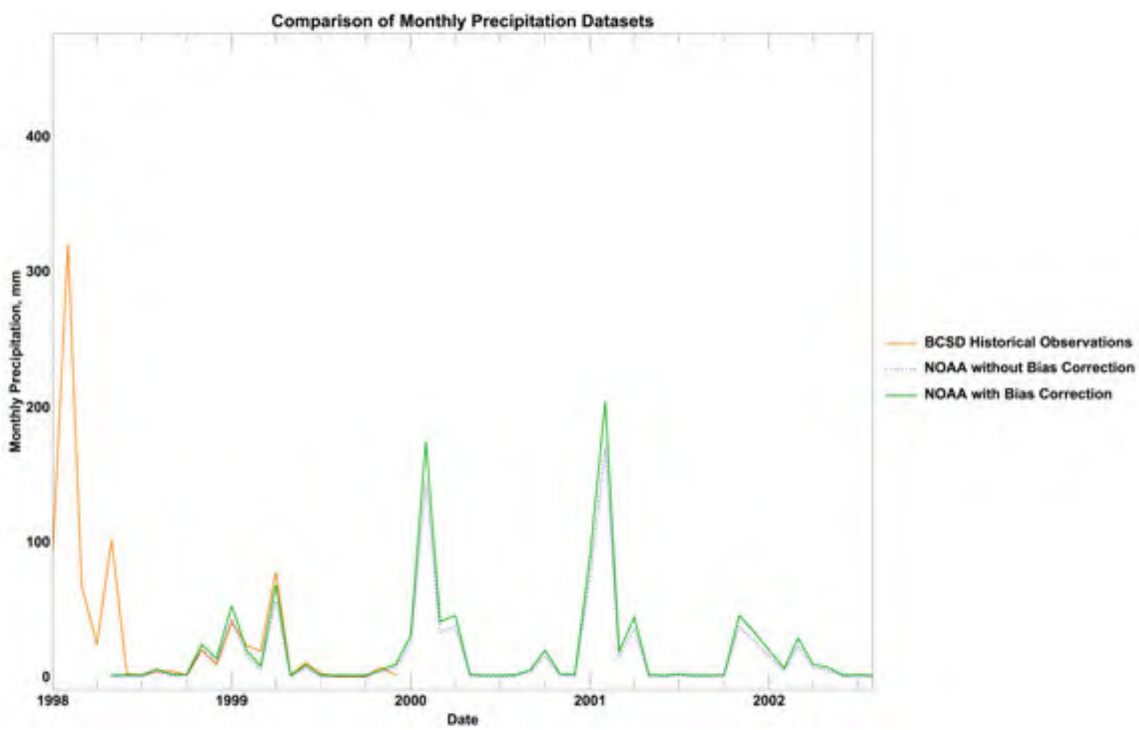
Total monthly local surface supplies within the IEUA management boundary for water years (July through June) 2010 through 2015 were provided by IEUA member agencies and represent the amount of water that is diverted, not total stream flow. To estimate these total local surface water supplies under different climate scenarios, relationships between climate variables and surface supply were derived using historical data. These relationships were then used to estimate future supplies under each climate scenario included in the analysis. Several different regression models were evaluated, and two models were found to reasonably represent the relationship between historical climate and historical supplies. One included both temperature and precipitation variables and the other only precipitation.

At the time of the analysis, the gridded BCSD historical climate observations were available only between 1950 and 1999. Therefore, to compare climate observations to the surface supply results for 2010 to 2015 an additional proxy data set for the 2010 to 2015 period was developed. Specifically, we used weather station observation at Ontario International Airport[3] (coordinates 34.05N, 117.61667W) contained in the Global Historical Climatology Network Database (GHCND) (Menne *et al.*, 2012), maintained by the National Oceanic and Atmospheric Administration (NOAA) National Climatic Data Center. The Ontario International Airport observation station reports monthly total precipitation and mean temperature observations from 1998 to present day.

We compared the monthly mean NOAA observed data to the monthly mean BCSD observed data for the overlapping period of May 1998 to June 2015. As expected we found very strong relationships for both monthly temperature and precipitation, although the NOAA observations were generally slightly drier than the BCSD data. We calculated a correction factor that we subsequently applied to the NOAA observed data to generate bias corrected datasets. Figure 23 shows a comparison of BCSD observed precipitation, NOAA observed monthly precipitation, and NOAA bias-corrected precipitation. This figure shows the strong relationship between the NOAA and BCSD datasets during the overlapping period of 1998 to 2000 and the very slight adjustment that was made to the NOAA data for months from 2000 and later.

[3] This station has Station ID GHCND:USW00003102 with latitude/longitude coordinates 34.05N, 117.61667W.

Figure 23: Comparison of BCSD, NOAA, and NOAA bias corrected monthly precipitation data on overlapping dates



NOAA bias corrected temperature and precipitation data, which were available until June 2015, were used to assess linear regressions relating monthly mean temperature and mean precipitation to total observed IEUA surface supplies. Additionally, given that a significant component of surface supply is due to melting snow pack, the potential of a delayed precipitation signal was evaluated. Four regressions were considered to estimate stream flow: (1) precipitation alone, (2) temperature alone, (3) precipitation and temperature, and (4) precipitation and a 12-month moving average of temperature. These regressions were analyzed with various lag times—applied to both temperature and precipitation—ranging from 0 to 6 months to search for a significant signal; a lag time of three months was found to have the lowest p-value among for all regressions and appeared to best reflect observed stream flow patterns. Note that the minimum p-value found with a lag time of 0 months was ≈ 0.429, while the p-values of the three best-fitting regression models at a lag time of three months were < 0.005. Shown below in Figure 24 is a comparison of each of the four regressions considered—each mapped over the NOAA bias corrected precipitation and/or temperature data—against observed surface flows. Figure 25 shows the same models aggregated to annual totals.

Figure 24: The four regression models versus observed flows

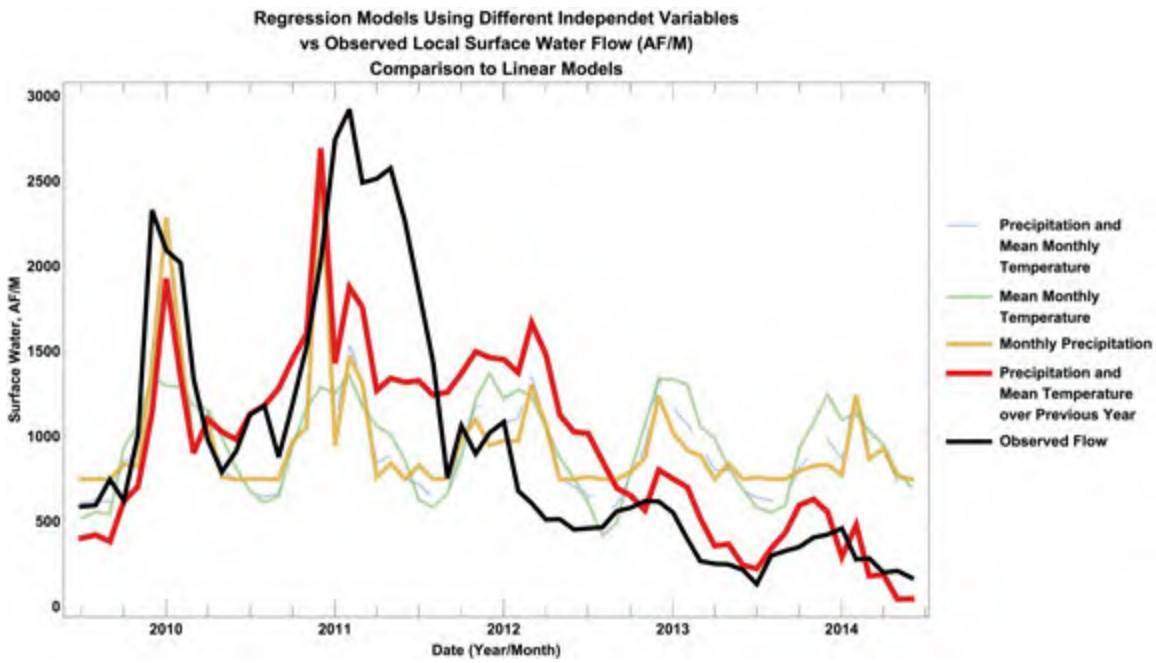


Figure 25: Four regression models averaged annually

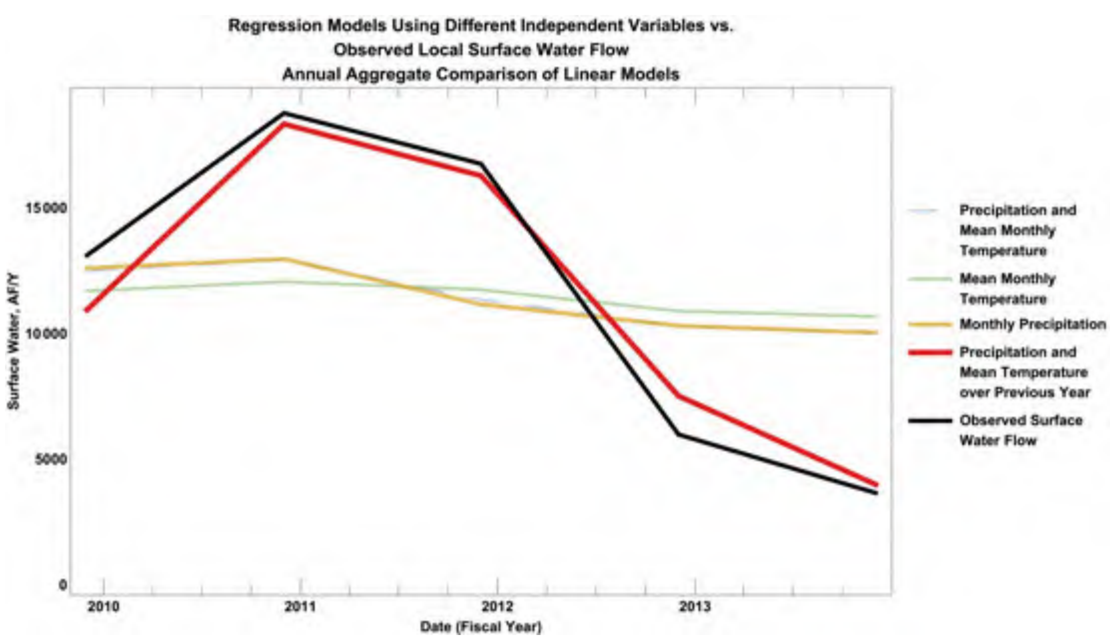

The regression model using precipitation and the mean temperature of the previous year (a moving average of twelve months) appears to generally follow the downward trend, while the precipitation only model, while accounting for much of the same variance, does not reflect the monthly downward trend in flow shown in Figure 24.

Estimated flows using both the precipitation and mean annual temperature under all 343 climate scenarios included, in addition to the mean estimated flow across all climate model outcomes, are shown in Figure 26. These same estimates generated using the precipitation only model are shown below in Figure 27.

Figure 26: Annual projected IEUA surface supplies using the Precipitation and Temperature regression model

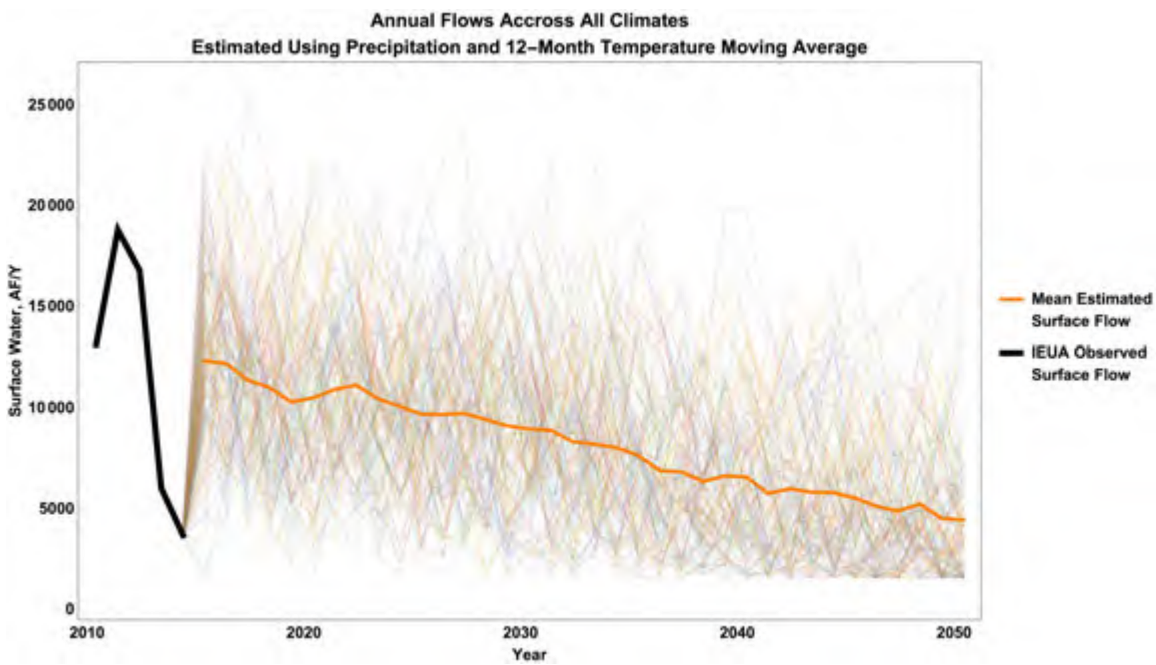

Figure 27: Annual projected IEUA surface supplies using the Precipitation regression model

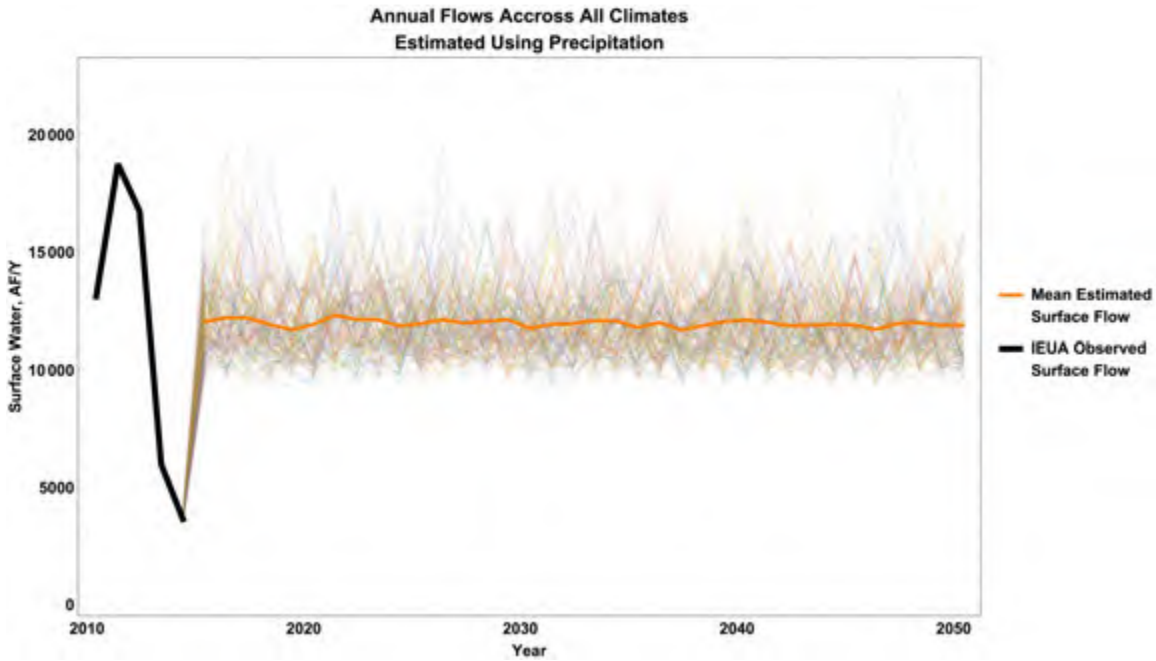


Stormwater

Stormwater used for Chino Basin groundwater replenishment is projected to increase from effectively 0 to 6,400 AF by 2020. The historical stormwater recharge has been included in the Chino basin groundwater supply. Any “new” stormwater supply could be from projects constructued under the 2013 Recharge Master Plan Update prepared by the Chino Basin Water Master. In absence of more detailed information on how future stormwater would vary with respect to precipitation, we apply the same regression formula develop for surface water supply to the baseline supply as well as any additional supply specified as part of a water management strategy.

Imports via Metropolitan Water District

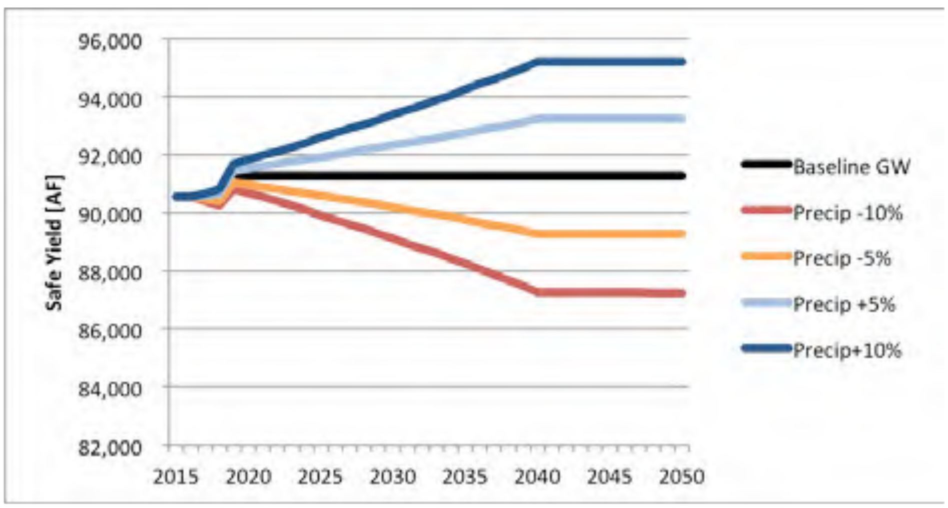
IEUA purchases water from MWD. Tier 1 water is generally used to meet urban indoor and outdoor demands. Per contract with MWD, IEUA must purchase at least 39,835 AF/year. Additional Tier 1 water, up to a total of 93,283 AF/year, is also typically made available to IEUA and is purchased when needed for direct use or groundwater replenishment. The baseline assumption for available additional Tier 1 water is 26,600 AF/year, for a total of just under 67,000 AF/year.

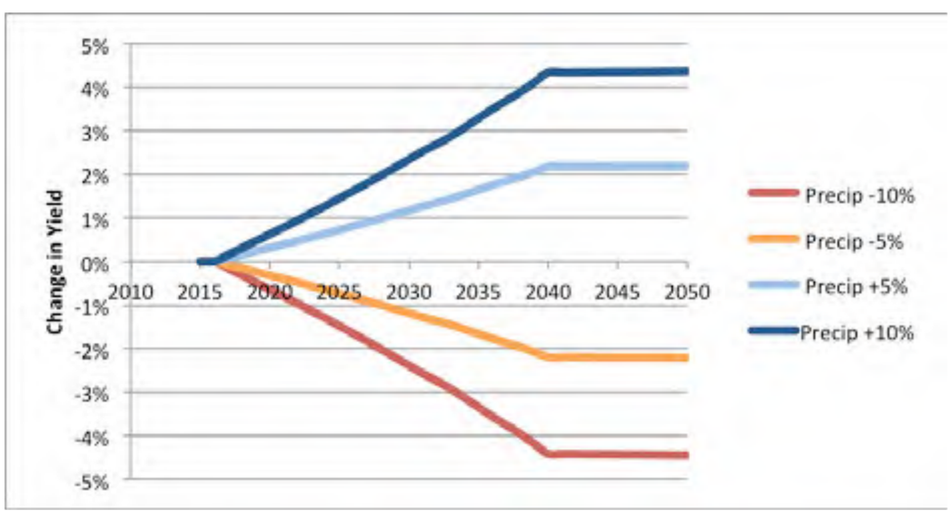
For this study we evaluate two possible levels of climate effect on additional Tier 1 water. In both cases, the total amount available declines beginning in 2021 through 2050. In one scenario, we assume additional Tier 1 water declines by 40%. In the other scenario, we assume declines of 80%. Note that these two level of water declines imply a total reduction in MWD Tier 1 water from 62,600 AF in the without climate change condition to 51,960 (for the 40% decline in additional supplies) and to 41,320 (for the 80% decline in additional supplies).

Chino Groundwater Basin

IEUA's share of Chino Basin's sustainable groundwater yield is set through actions of the Chino Basin Water Master. Under current basin conditions, the amount of groundwater available to the appropriators within the IEUA service area is 91,266 AF. An analysis by Wildermuth Environmental Inc. determined the sensitivity of IEUA's allowable production as a function of long-term precipitation trends (Figure 28). These data show that across the four scenarios evaluated, the safe yield would decline 0.44% for each 1% decline in long-term precipitation.

Figure 28: Safe yield over time for the baseline and four trends in precipitation (top); change in safe yield (as compared to 2015 across four trends in precipitation (bottom)





We then modified the Chino Basin safe yield by the product of the long-term precipitation trend and the empirically derived scaling factor. For example, groundwater safe yield would be reduced 4.4% by 2040 for a climate scenario that exhibits a long-term precipitation trend of -10%.

Key Simulation Results

The WEAP IEUA model simulates annual water supply and demand from 2010 to 2015. For this analysis, the key outputs reviewed included:

- Urban indoor and outdoor demand
- Supplies used to meet urban demand
- Unmet urban demand
- Recycled water inflows and outflows
- Chino Basin inflows and outflows

This section shows results for these outputs from the WEAP IEUA model for a single simulation—high demand scenario and historical climate.

Figure 29 shows annual indoor potable demand and outdoor demand—both potable and recycled. Note that indoor demand gradually increases each year, whereas outdoor demand varies year-to-year. The outdoor demand variation is due to the historical climate used in this simulation.

Figure 29: Urban indoor and outdoor demand for high demand scenario and historical climate

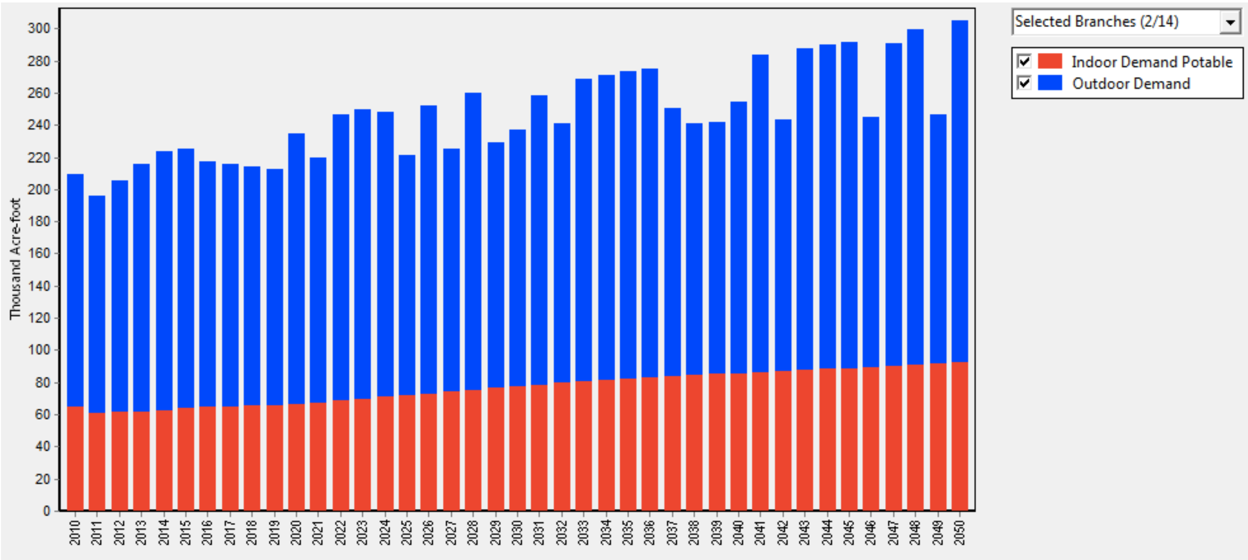


Figure 30 shows the mixture of supplies used to meet the demands in Figure 29. The largest source is Chino groundwater supplies. MWD Tier 1 supplies (minimum and additional) provide significant water. Lastly, recycled water provides about 20 percent of the supply.

Figure 30: Supplies used to meet demand for high demand scenario and historical climate

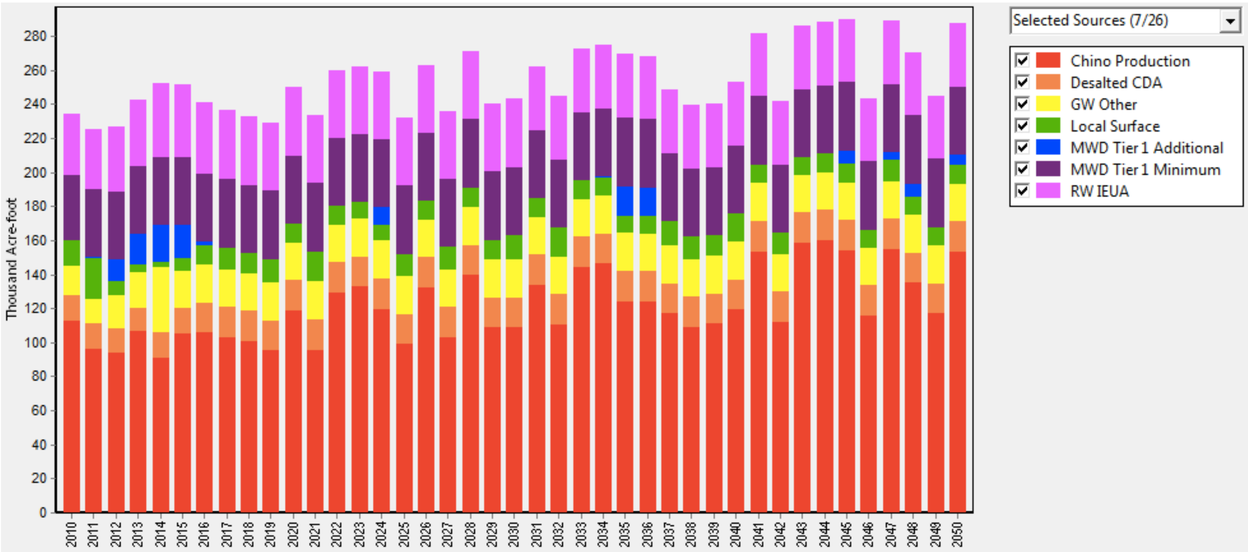

Figure 31 focuses on the recycled water portion of the IEUA system. The top bars show the inflows—return flow from IEUA indoor demand and some small amount of wastewater from outside the IEUA service area. The bottom bars show the destinations for the recycled water supply including: outdoor urban use (Recycled Direct), agricultural use (Ag RW Demand), the Santa Ana River (SAR Obligation and Downstream Flow), recharge to the Chino Basin (Req. Supp. Recharge and Recycled GW Recharge, Additional GW Recharge). Note that Downstream Flow represents more available recycled water than is needed to meet demand for recycled water. In simulations with low urban demand, there is no excess recycled water and instead shortages.

Figure 31: Sources of recycled water (top) and uses of recycled water (bottom) for high demand scenario and historical climate

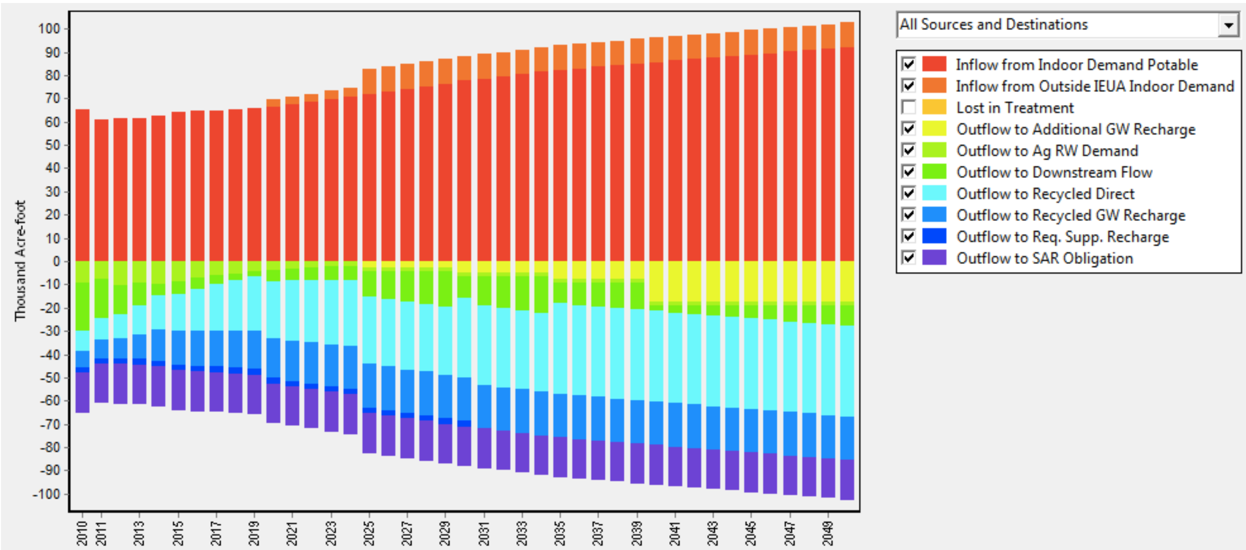

Figure 32 shows the inflows and outflows to the Chino Groundwater Basin. Natural Recharge is the largest source, but one can see how the different replenishment sources increase the inflows over time. The primary use of groundwater is to meet outdoor demands.[4] There is some modest increase and decrease in storage over the years.

[4] In reality, potable water for indoor and outdoor use are served using common water mains. The partitioning of supplies to indoor and outdoor potable use in the model reflects the priority structure used to ensure that shortages, if any, are experienced by outdoor uses first.

Figure 32: Inflows (top) and outflows (bottom) to the Chino Basin for high demand scenario and historical climate

A&N Technical Services “Indoor and Outdoor Demands”

A & N Technical Services, Inc.

Memorandum

To: Jason Pivovaroff, IEUA

From: **David Pekelney and Thomas Chesnutt**

Date: January 24, 2014

Re: **Inferring Indoor and Outdoor Water End Uses in the IEUA Service Area**

Introduction

This memo documents the estimation of indoor and outdoor water end uses for water demand in the IEUA service area. This estimation of indoor/outdoor end uses is conducted by customer class—single family residential, multi-family residential, and commercial-industrial-institutional (CII). Indoor end uses are of particular interest to planners tasked with designing wastewater systems and recycled water systems because it helps them establish capacity requirements. Both indoor and outdoor use is of great interest to planners tasked with designing Water Use Efficiency (conservation) programs. Although much has already been accomplished with indoor conservation, there is some level of remaining potential for water savings. WUE planners have particular interest in outdoor use because it is generally assumed to be a large share of total use with large remaining potential for savings.

Two methods were used to estimate outdoor use across customer classes. The first method is the minimum month method that has been historically used in the water industry—this method assumes that the minimum month of water demand is 100 percent indoor end uses. Though we believe that this is a counterfactual assumption in the IEUA service area (it assumes exactly zero outdoor irrigation in the winter) we provide estimates using the minimum month method to serve as a point of comparison. The second method develops an estimate of winter irrigation from dedicated irrigation meters and applies this nonzero assumption instead. Termed a "seasonal variation" method, it applies the seasonal variation from dedicated irrigation meters to mixed meter customer classes.

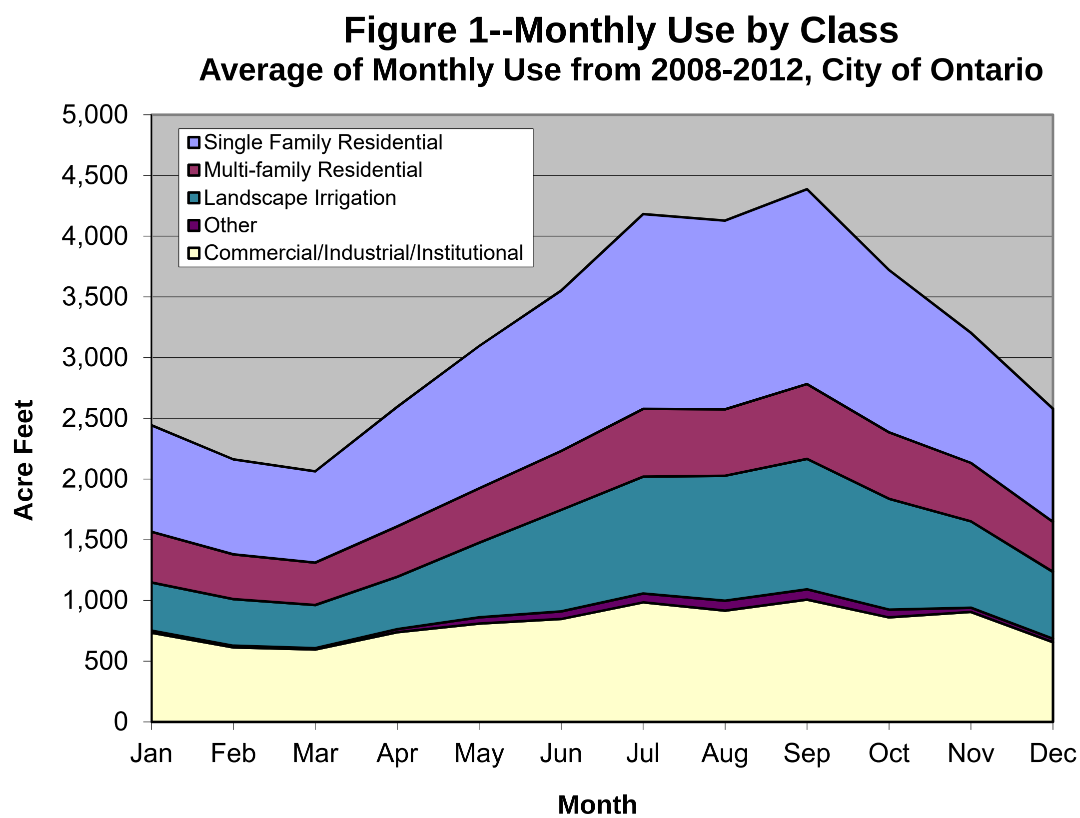
Data

The data used are from the California Department of Water Resources, Public Water System Statistics filings for the City of Ontario for the years 1993 to 2012. These data are billing system summaries at the monthly level. Several other retailers provided monthly use summaries; however, these were generated with bimonthly billing cycles. Since different retailers can apportion bimonthly billing into calendar months using different methods, it is more consistent to stick to the monthly data generated with monthly billing. Although CVWD, Upland, and MVWD provided monthly data (based on bimonthly billing), we used the City of Ontario data for this analysis because it was the only retailer to provide monthly use data generated by monthly billing.

Table 1 shows the average use from 2008 to 2012 summed by customer class. Figure 1 shows the sum of water use by month. The strong seasonal pattern reflects irrigation needs during the characteristic hot and dry summers.

Table 1 – Average Use, 2008 to 2012, City of Ontario

Class	Use (AF)	Percent
Single Family Residential	13,993	36.7%
Multi-family Residential	5,647	14.8%
Commercial/Industrial/Institutional	9,666	25.4%
Landscape Irrigation	8,259	21.7%
Other	549	1.4%
Total	38,114	100.0%



Methods

Outdoor end uses are directly measured by dedicated irrigation meters. Many other types of water meters--single family, multi family, commercial, industrial, and institutional--can be measuring both indoor and outdoor end uses. If not measured or observed directly, planners are forced to rely on inference or judgment. For IEUA, we have conducted two methods to infer outdoor use for all sectors.

Minimum Month Method

The most common method employed to infer outdoor use is to assume the winter use is all indoors. (This assumption may be closer to the truth in wetter or colder climates.) For example, if we calculate winter minimum use times 12 months we have inferred total indoor use for the year. Total use for the year minus indoor use then equals outdoor use.

In Table 2 below, we find that outdoor use calculated with the "minimum winter use is indoor use" method is 46%. The method underestimates outdoor use because there is likely to be at least some winter irrigation in dry climates. Variations on this method include daily accounting and various ways to define winter minimum. Note the results of this method will vary considerably from year to year; the reader is cautioned when using results from one year for planning purposes and we used for this analysis the monthly average over the five most recent years for which data were available (2008 to 2012).

Table 2 – Percent Outdoor Use

Class	Total	Minimum Month Method	Seasonal Variation Method
Single Family Residential	13,993	36%	58%
Multi-family Residential	5,647	26%	43%
Commercial/Industrial/Institutional	9,666	26%	42%
Landscape Irrigation	8,259	100%	100%
Other	549	75%	100%
Total	38,114	46%	62%

Seasonal Variation Method

The second method to infer outdoor use consists of employing the pattern of seasonal variation with dedicated irrigation meters and applying it to other sectors with mixed meters. The reasoning is that with dedicated irrigation meters we can measure winter irrigation. Thus, we can observe the relative water use in winter and summer irrigation seasons and calculate a parameter from variables that are observable in other sectors. For example, by calculating the ratio of winter minimum to the seasonal range we have a function of variables observable for sectors other than dedicated irrigation meters. This method will result in a higher estimate of outdoor water use than using minimum month. The method relies on the assumption that the seasonal variation of outdoor use is the same for sites with dedicated meters as for sites with mixed meters.

Due to the variability of landscape water use from year to year, we expect the calculated parameter to vary considerably from year to year. For this reason, we calculated the parameter (ratio of winter minimum to seasonal range) for each year for which we could collect data (1993 to 2012) and took the average. We applied this long term average to the monthly average of the most recent five years of consumption data (2008 to 2012) because of the changing distribution of water use by customer class as more dedicated irrigation meters are employed.

Figure 2 shows the use from irrigation-only meters, with winter irrigation illustrated in blue and the seasonal range in red for one example year (2011).

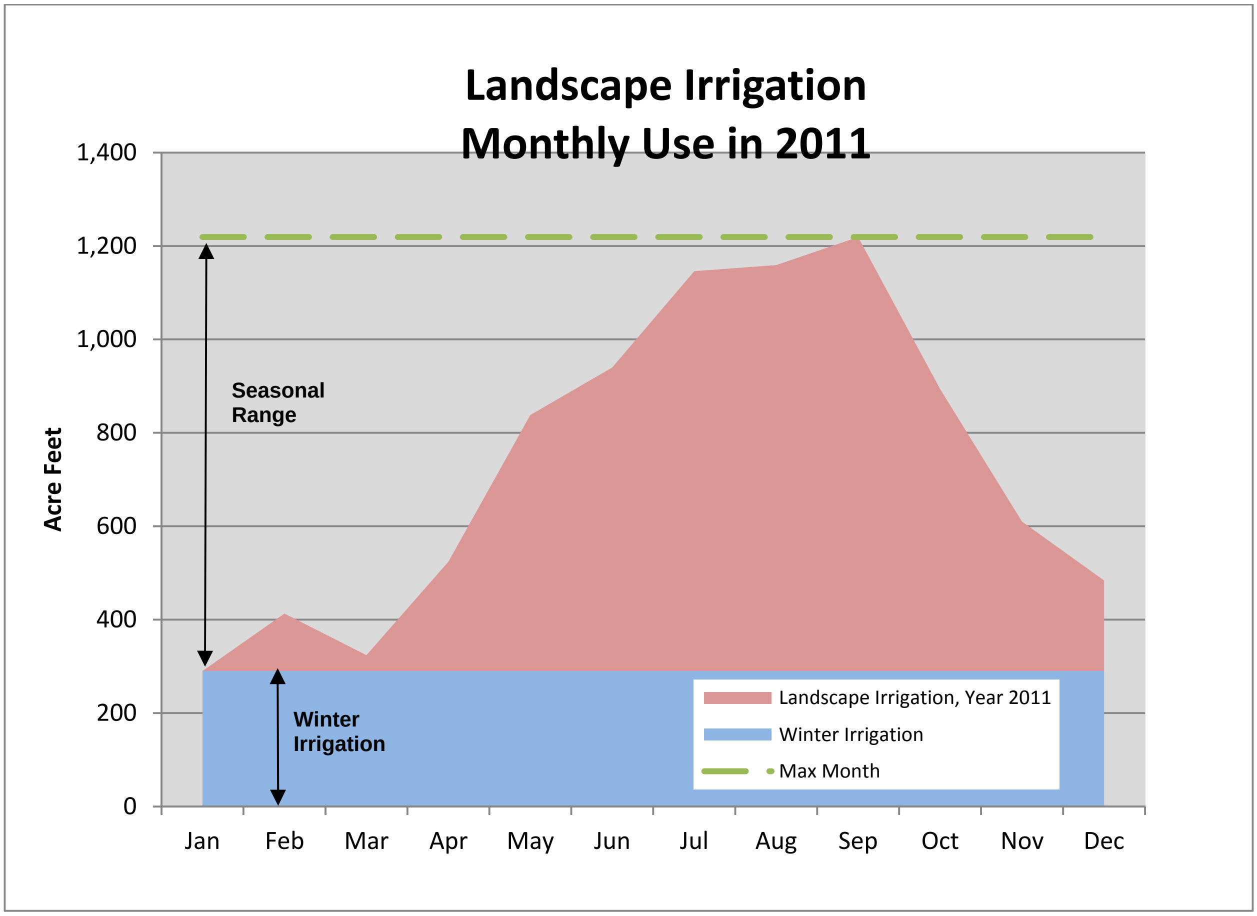


Figure 2 shows winter irrigation is 31% of seasonal range between summer and winter for dedicated irrigation accounts for the year 2011. We repeated this calculation for each year for which were able to collect data (1993 to 2012) and averaged the values to get the result we apply to customer sectors with mixed meters (31%).

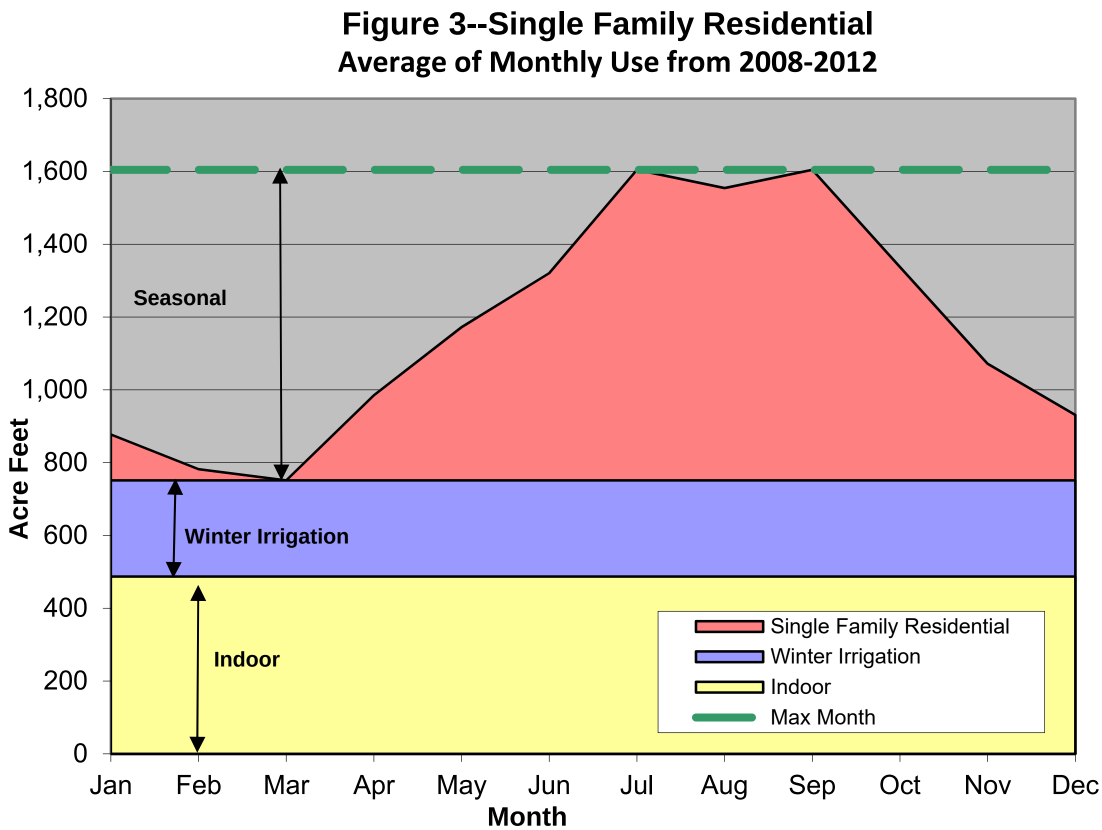
Seasonal range and winter minimum are observable for non-irrigation classes. If we assume that winter irrigation is also 31% of seasonal range for the non-irrigation customer categories, we can infer their winter irrigation, and thus indoor and outdoor use.



For example, Figure 3 shows winter irrigation calculated as 31% of seasonal range for the single family residential sector. Total outdoor use (red+blue in this graph) is, thus, 58% of total use for the year (red+blue+yellow). In contrast, using the minimum month for the single family sector results in 36% outdoor use (red area only).

Conclusions and Recommendations

The seasonal variation method estimates outdoor end uses to compose 62 percent of M&I water demand (across all customer sectors) in the IEUA service area. We recommend using the seasonal variation method because we know the minimum month method systematically underestimates outdoor water use in climates where there is winter irrigation such as IEUA.

Although the minimum month method systematically underestimates outdoor use and overestimates indoor use--and we do not recommend using it for planning water resource investments--it is a commonly used method that is simple to implement and, thus, it may have value as a comparison benchmark.

This analysis used empirical measures using monthly-billed data from one of the larger retail water service areas. We can improve the reliability of the results by expanding the data set to include other IEUA service areas that utilize monthly billing.

As stated in the Introduction, estimation of indoor/outdoor split is of particular interest because it aids with designing wastewater system and recycled water systems to establish capacity requirements. Indoor use is directly related to wastewater flows; however, that does not mean they should be directly compared. Indoor use and wastewater flows are not commensurate without accounting for the following:

- The water volume used in the indoor/outdoor estimate derives from customer consumption measures. If a comparison to production measures is desired, one must account for factors that explain the differences between production and consumption measures: system loss, unaccounted for water, meter accuracy, and unmetered water. Additionally, if applying the estimate of indoor water use to total production, agricultural use needs to be separately accounted for because the estimates of indoor water use were constructed with M&I consumption data only.
- Some indoor use does not go down the drain because of cooking, consumption, cleaning, indoor plants, and other uses. These indoor water uses do not translate into wastewater flows.
- Parts of the unincorporated areas of IEUA are not hooked up to the sewer system—they still use septic systems—and their indoor use also does not translate to sewer flow.
- Any loss or gain in volume between the customer and the wastewater treatment plant would also need to be accounted for. For example, infiltration and inflows, wastewater system loss, and evaporation are potential effects on wastewater volume.
- It is easy to observe that water consumption data is inherently more variable than wastewater inflow measures due to outdoor use and weather variability. The estimate of indoor water use as a proportion of total M&I use in the City of Ontario is 38% over the years 1992-2012. If this proportion is calculated using the most recent five years from 2008 to 2012, the proportion of indoor water use is only 36%. This proportion should clearly not be thought of as a constant over time.

In sum, although most of indoor water use does indeed flow to the treatment plant, the estimates of wastewater flow and the indoor water use are not directly comparable without accounting for the above factors.

Appendix 4:

A&N Technical Services “Demand Influencing Factors”

Baseline Demand Influences

Table 1 summarizes the demand influences that were incorporated into the corresponding baseline demand forecast. The following sections define each level of influence, or adjustment that was applied to the normalized demand forecast.

Table 1: Baseline demand influences incorporated within each demand forecast

	Baseline Demand Influences					
	Economic Cycle	**Household Income**	**Housing Density**	**Weather**	**Climate Change**	**Customer Response**
Upper Forecast	Baseline	Baseline	City General Plan	Multiple Dry	High	Permanent
Lower Forecast	Baseline	Baseline	SCAG	Dry	Baseline	Permanent
Planning Forecast	NA	NA	DWR	NA	NA	NA

Notes: NA = Not Applicable

Economic Cycle

Ability to specify how strong and weak market conditions impact demand. The effect from market conditions was defined from historical demand data through the normalizing process.

- **Weak –** implies weak market conditions and demand is reduced by 6.55%.
- **Baseline –** implies that demand will not change and market conditions will remain normal/average.
- **Strong –** implies strong market conditions and demand will increase by 6.55%

Median Household Income

Ability to incorporate potential changes in demand related to household income. The following alternatives were based on the following assumptions.

- **Low** – median household income growth is below the baseline rate and reduces over time at minus 1% percent per year. Implies that demand will potentially be reduced.
- **Baseline—** median household income trends at the predicted rate per the 2012 SCAG RTP/SCS. Implies that demand will not change and will remain normal/average.
- **High** – median household income growth increases faster than the baseline rate and increases at plus 1% percent per year. Implies that demand will potentially be increased.

Housing Density

Ability to adjust the water use factor applied to each occupied housing unit based upon the expected density of future development. The density values below are aggregated regional values for the Agency's service area. In general, higher housing densification tends to have lower water use per unit caused by reduced landscape areas and more stringent water use efficiency standards.

- **City General Plan –** incorporates housing density reflective of the 2014 City General Plans.
    - Single family residential density range 1.2 – 4.2 units per acre
    - Multi-family residential density range 9.7 – 17.3 units per acre
- **Baseline –** implies that future residential development resembles past/traditional dwelling units per land area.
- **SCAG** - incorporates housing density reflective of the 2012 S.California Association of Governments Regional Transportation Plan/Sustainable Communities Strategy (2012 SCAG RTP/SCS).
    - Single family residential density range 2.3 – 5.4 units per acre
    - Multi-family residential density range 8.4 – 17.0 units per acre
- **DWR –** does not incorporate housing density, assumed a modified version of the current DWR State Model Water Efficient Landscape Ordinance. Assumed the following efficiency standards:
    - 70% relative evapotranspiration (Eto) for existing landscapes
    - 60% relative Eto for new landscapes
    - Indoor water use for future development of 55 gallons per capita day (GPCD) in 2015 to 35 GPCD by 2040.
    - Number of occupied housing units per SCAG RTP/SCS
    - Assumed 62% of total demand for residential use

Weather

Ability to specify how weather conditions impact demand from below and above average/normal conditions. The effect of weather variation was defined from historical demand data through the normalizing process.

- **Wet –** implies that demand will be decreased by 3.74% due to below normal temperature and increased wet periods.
- **Baseline** - implies that demand will not change and weather will remain normal/average conditions.
- **Dry –** implies that demand will increase by 3.74% due to above normal temperature and reduced wet periods.
- **Multiple Dry –** implies that demand will increase by 5.98% due to extended periods of above normal temperature and reduced wet periods.

Climate Change

Long term climate change is modeled by using recent Global Climate Change model predictions of potential increases in temperature and corresponding impact to demands. The Regional Climate Trends and Scenarios from the Southwest U.S. were referenced from the National Oceanic and Atmospheric Administration (NOAA) Technical Report NESDIS 142-5. (http://scenarios.globalchange.gov/report/regional-climate-trends-and-scenarios-us-nationalclimate-assessment-part-5-climate-southwest)

- **Baseline** - implies that demand will not change and climate will remain at normal/average conditions.
- **Median** (50^{th} percentile) – implies that expected temperature will increase by 2.7 degree Fahrenheit due to climate change. This would increase demands by 3.2% by 2040.
- **High** (80^{th} percentile) – implies that expected temperature will increase by 3.6 degree Fahrenheit due to climate change. This would increase demands by 4.3% by 2040.

Customer Response and Water Use Behavior

Defines how much of recent demand reductions will persist into the future that is permanent. The effect from recent customer response and water use behavior was defined from historical demand data through the normalizing process.

- **Baseline** – implies that demand will not change and everything will return to the normal, or bounce back to normal/average conditions.
- **Permanent** – implies that the 4.6% recent reduction is a permanent lifestyle change and continues to 2040.

Baseline Demand Comparison: Normalized vs. Adjusted

Figure A presents the Upper, Lower and Planning Forecasts under Baseline assumptions, therefore all demand influences are assumed to be normal or under average conditions, except for housing density. Housing density remained as indicated in Table 1. Figure B presents the same demand forecasts with the demand influences indicated in Table 1. As shown, there is a slight difference in the forecast envelope when you compare Figure A to B. The common attribute between the two Figures is housing density; therefore as shown, the other demand influences did not have as much impact to the demand forecasts as housing density did. To note, each demand influence adjusts the normalized water use factors that are applied regional growth projections for number of households and employees per sector.

Figure A: Baseline demand forecasts under normal or average conditions.

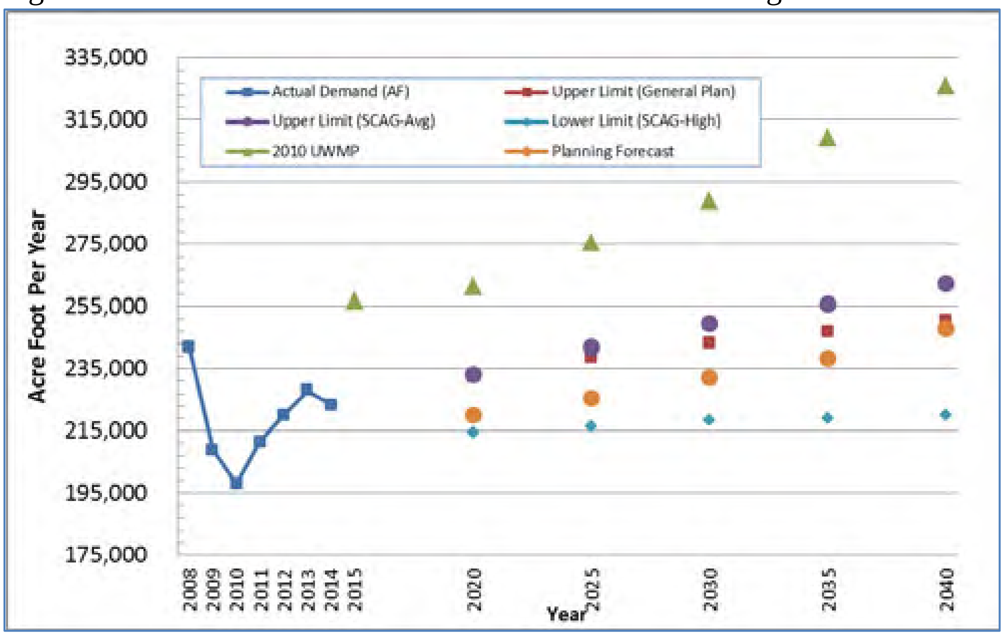


Figure B: Baseline demand forecasts under demand influences per Table 1.

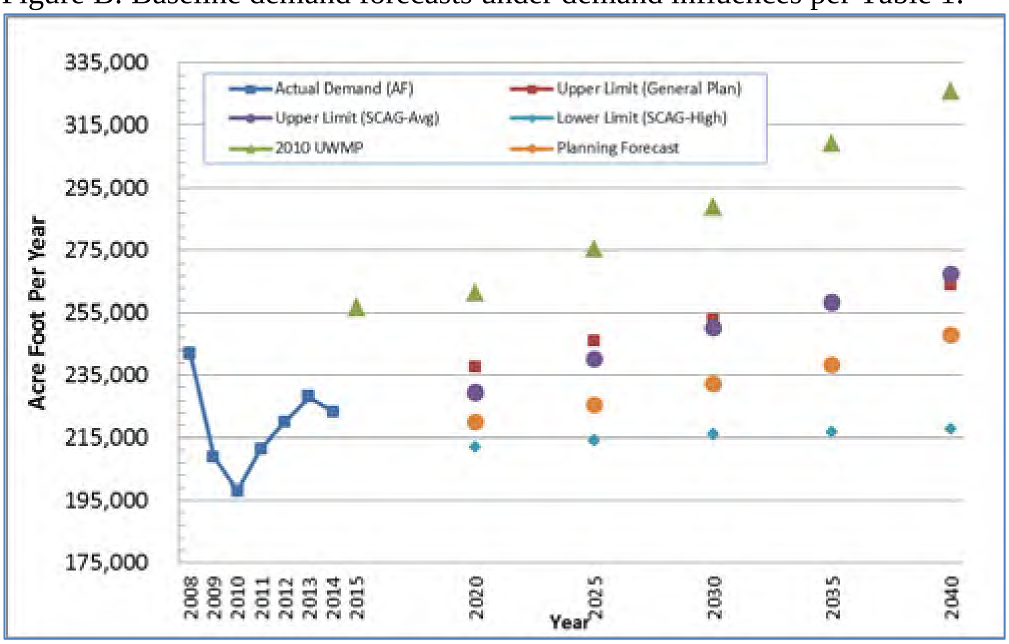

Appendix 5:

Full IRP Technical Committee Identified Project List

ID	Project Name	Description	AF yield	Years to "wet water" yield	Increased groundwater in storage?	Increases water level in critical GW management zones?	Increased stormwater capture/recharge?	Increased permeability or natural infiltration for	Provide additional recycled water?	Reduce Dependence on imported water from MWD during dry	Increase local water supplies?	Emergency local supply redundancy?	Decrease reliance on local surface water during dry years?	Requires conservation in existing development?	Requires demand management in new development?	Reduce TDS and/or nitrates in GW?	Decrease net energy consumption?	Increase capacity of wet year water ("big	Eligible for grant funding?	Technical feasibility/ease of
1	Groundwater Treatment (Rehab)-Increment 1	This project category will rehabilitate an existing groundwater production wells decommissioned due to water quality concerns. It is assumed that additional pumping would be limited by the volume of recharge occurring (over operating safe yield). Increased well operation could supplement annual demands or intermittent to help offset losses in another water supply. Increment 1 will provide up to 5,000 AFY of production.	5,000	2	0	0	1	1	1	2	2	1	1	1	1	2	2	1	2	2
2	Groundwater Treatment (Rehab)-Increment 2	This project category will rehabilitate an existing groundwater production wells decommissioned due to water quality concerns. It is assumed that additional pumping would be limited by the volume of recharge occurring (over operating safe yield). Increased well operation could supplement annual demands or intermittent to help offset losses in another water supply. Increment 1 + 2 will provide up to 10,000 AFY of production.	5,000	2	0	0	1	1	1	2	2	1	1	1	1	2	2	1	2	2
3	Groundwater Treatment (new)-Increment 1	This project category will construct a new groundwater production well and treatment facility to address water quality concerns. It is assumed that additional pumping would be limited by the volume of recharge occurring (over operating safe yield). Increased well operation could supplement annual demands or intermittent to help offset losses in another water supply. Increment 1 will provide up to 5,000 AFY of production.	5,000	2	0	0	1	1	1	2	2	1	1	1	1	2	2	1	1	2
4	Groundwater Treatment (new)-Increment 2	This project category will construct a new groundwater production well and treatment facility to address water quality concerns. It is assumed that additional pumping would be limited by the volume of recharge occurring (over operating safe yield). Increased well operation could supplement annual demands or intermittent to help offset losses in another water supply. Increment 1 + 2 will provide up to 10,000 AFY of production.	5,000	2	0	0	1	1	1	2	2	1	1	1	1	2	2	1	1	2
5	Production Wells-Increment 1	With increasing groundwater recharge to the Chino Basin, new production wells may need to be constructed to recover the additional groundwater. It is assumed that additional pumping would be limited by the volume of recharge occurring (over operating safe yield). Well operation could supplement annual demands or intermittent to help offset losses in another water supply. Increment 1 will provide up to 5,000 AFY of production	5,000	2	0	0	1	1	1	2	2	1	1	1	1	1	2	1	2	2
6	Production Wells-Increment 2	With increasing groundwater recharge to the Chino Basin, new production wells may need to be constructed to recover the additional groundwater. It is assumed that additional pumping would be limited by the volume of recharge occurring (over operating safe yield). Well operation could supplement annual demands or intermittent to help offset losses in another water supply. Increment 1+2 will provide up to 10,000 AFY of production	5,000	2	0	0	1	1	1	2	2	1	1	1	1	1	2	1	2	2
7	Production Wells-Increment 3	With increasing groundwater recharge to the Chino Basin, new production wells may need to be constructed to recover the additional groundwater. It is assumed that additional pumping would be limited by the volume of recharge occurring (over operating safe yield). Well operation could supplement annual demands or intermittent to help offset losses in another water supply. Increment 1-3 will provide up to 15,000 AFY of production	5,000	2	0	0	1	1	1	2	2	1	1	1	1	1	2	1	1	2
8	Production Wells-Increment 4	With increasing groundwater recharge to the Chino Basin, new production wells may need to be constructed to recover the additional groundwater. It is assumed that additional pumping would be limited by the volume of recharge occurring (over operating safe yield). Well operation could supplement annual demands or intermittent to help offset losses in another water supply. Increment 1-4 will provide up to 20,000 AFY of production	5,000	2	0	0	1	1	1	2	2	1	1	1	1	1	2	1	1	2
9	WRCRWA RW Intertie	The Western Riverside County Regional Wastewater Authority (WRCRWA) Plant intertie would allow for the delivery of recycled water from the WRCRWA Plant to be used in the IEUA southern service area. This would also allow additional recycled water to be delivered into the northern service area groundwater recharge basins by reducing the demand from the RP-1 930 pressure zone pump station. Intertie would occur within the 800/930 Pressure Zones.	4,500	10	2	1	1	1	2	2	2	2	1	1	1	1	2	1	1	1
10	Rialto RW Intertie	The Rialto intertie project would allow for delivery of recycled water from the Rialto WWTP to be used in the IEUA service area. The intertie could occur near the RP-3 groundwater recharge basins. This concept could involve the Inland Valley Pipeline, LLC (IVP) to convey water between Rialto WWTP and IEUA's recycled water distribution system. Supply could be used for direct, GWR or other reuse strategy.	4,500	10	2	2	1	1	2	2	2	2	1	1	1	1	2	1	1	1
11	Pomona RW Exchange/Transfer	The City of Pomona does not currently use all of the treated effluent from the Pomona WRP. One concept would involve partnering to develop and expand their recycled water facilities in exchange for an agreed amount of their Chino Basin groundwater right. Could include other supply transfer agreement such as reclaimable waste and/or groundwater.	2,500	10	2	2	1	1	1	2	2	1	1	1	1	1	2	1	1	1
12	RP-1 RW Injection-Increment 1	This project would construct an advanced water filtration (e.g. process treatment that combines micro or ultrafiltration) facility at RP-1 to further treat tertiary effluent to allow the water to be injected directly into Chino Basin. The sizing of the facility and the volume to be produced will be determined as part of the portfolio development process. Increment 1 facility would be sized for 2,500 AFY.	2,500	9	2	1	1	1	1	2	2	1	1	1	1	2	0	1	2	2

13	RP-1 RW Injection-Increment 2	This project would construct an advanced water filtration (e.g. process treatment that combines micro or ultrafiltration) facility at RP-1 to further treat tertiary effluent to allow the water to be injected directly into Chino Basin. The sizing of the facility and the volume to be produced will be determined as part of the portfolio development process. Increment 1+2 facility would be sized for 5,000 AFY.	2,500	9	2	1	1	1	1	2	2	1	1	1	1	2	0	1	1	2
14	RP-1 RW Injection-Increment 3	This project would construct an advanced water filtration (e.g. process treatment that combines micro or ultrafiltration) facility at RP-1 to further treat tertiary effluent to allow the water to be injected directly into Chino Basin. The sizing of the facility and the volume to be produced will be determined as part of the portfolio development process. Increment 1-3 facility would be sized for 7,500 AFY.	2,500	9	2	1	1	1	1	2	2	1	1	1	1	2	0	1	1	2
15	Satellite RW Injection-Increment 1	This project category would construct a satellite (outside of RP-1) wastewater treatment plant with advanced water filtration (e.g. process treatment that combines micro or ultrafiltration) to allow the water to be injected directly into Chino Basin. The location, sizing and volume to be produced will be determined as part of the portfolio development process. Increment 1 facility, or facilities would have a capacity of 2,500 AFY.	2,500	5	2	2	1	1	1	2	2	1	1	1	1	2	0	1	2	2
16	Satellite RW Injection-Increment 2	This project category would construct a satellite (outside of RP-1) wastewater treatment plant with advanced water filtration (e.g. process treatment that combines micro or ultrafiltration) to allow the water to be injected directly into Chino Basin. The location, sizing and volume to be produced will be determined as part of the portfolio development process. Increment 1+2 facility, or facilities would have a capacity of 5,000 AFY.	2,500	5	2	2	1	1	1	2	2	1	1	1	1	2	0	1	1	2
17	Satellite RW Injection-Increment 3	This project category would construct a satellite (outside of RP-1) wastewater treatment plant with advanced water filtration (e.g. process treatment that combines micro or ultrafiltration) to allow the water to be injected directly into Chino Basin. The location, sizing and volume to be produced will be determined as part of the portfolio development process. Increment 1-3 facility, or facilities would have a capacity of 7,500 AFY.	2,500	5	2	2	1	1	1	2	2	1	1	1	1	2	0	1	1	2
18	Desalter Recovery Improvement	The existing Chino Basin I Desalter (CD-1) recovers approximately 75 percent of water. Improvements could be done to increase recovery to approximately 90 percent. This water would be conveyed through the existing potable water system.	1,500	3	1	1	1	1	1	2	2	1	1	1	1	2	1	1	1	2
19	RW Direct Use Expansion-Increment 1	IEUA developed a new Recycled Water Program Strategy concurrent with the IRP. This project category will be used to determine the potential interest in expanding the direct use system beyond the Agency's Ten Year CIP. Includes the reuse of regional wastewater supply, approximately 83,000 AFY by 2035 and potential recycled water interties. Increment 1 facilities would increase direct use beyond baseline supply by 5,000 AFY.	5,000	15	1	1	1	1	1	2	2	1	1	1	1	0	2	1	2	2
20	RW Direct Use Expansion-Increment 2	IEUA developed a new Recycled Water Program Strategy concurrent with the IRP. This project category will be used to determine the potential interest in expanding the direct use system beyond the Agency's Ten Year CIP. Includes the reuse of regional wastewater supply, approximately 83,000 AFY by 2035 and potential recycled water interties. Increment 1+2 facilities would increase direct use beyond baseline supply by 10,000 AFY.	5,000	20	1	1	1	1	1	2	2	1	1	1	1	0	2	1	1	2
21	RW Direct Use Expansion-Increment 3	IEUA developed a new Recycled Water Program Strategy concurrent with the IRP. This project category will be used to determine the potential interest in expanding the direct use system beyond the Agency's Ten Year CIP. Includes the reuse of regional wastewater supply, approximately 83,000 AFY by 2035 and potential recycled water interties. Increment 1-3 facilities would increase direct use beyond baseline supply by 15,000 AFY.	5,000	25	1	1	1	1	1	2	2	1	1	1	1	0	2	1	1	2
22	RW Direct Use Expansion-Increment 4	IEUA developed a new Recycled Water Program Strategy concurrent with the IRP. This project category will be used to determine the potential interest in expanding the direct use system beyond the Agency's Ten Year CIP. Includes the reuse of regional wastewater supply, approximately 83,000 AFY by 2035 and potential recycled water interties. Increment 1-4 facilities would increase direct use beyond baseline supply by 20,000 AFY.	5,000	25	1	1	1	1	1	2	2	1	1	1	1	0	2	1	1	2
23	Existing GWR Basin Improvements beyond RMPU-Increment 1	The 2013 Chino Basin RMPU recommended a set of preferred projects to improve recharge at the existing groundwater spreading basins. This project category represents the next increment of additional groundwater recharge (imported water and/or recycled water) capable at the existing facilities. Increment 1 facilities would increase recharge at existing basins within the Chino Basin by an additional 2,500 AFY.	2,500	15	2	2	1	1	1	2	2	1	1	1	1	0	2	1	2	2
24	Existing GWR Basin Improvements beyond RMPU-Increment 2	The 2013 Chino Basin RMPU recommended a set of preferred projects to improve recharge at the existing groundwater spreading basins. This project category represents the next increment of additional groundwater recharge (imported water and/or recycled water) capable at the existing facilities. Increment 1+2 facilities would increase recharge at existing basins within the Chino Basin by an additional 5,000 AFY.	2,500	20	2	2	1	1	1	2	2	1	1	1	1	0	2	1	2	2
25	Existing GWR Basin Improvements beyond RMPU-Increment 3	The 2013 Chino Basin RMPU recommended a set of preferred projects to improve recharge at the existing groundwater spreading basins. This project category represents the next increment of additional groundwater recharge (imported water and/or recycled water) capable at the existing facilities. Increment 1-3 facilities would increase recharge at existing basins within the Chino Basin by an additional 10,000 AFY.	5,000	25	2	2	1	1	1	2	2	1	1	1	1	0	2	1	1	2

26	Existing GWR Basin Improvements beyond RMPU-Increment 4	The 2013 Chino Basin RMPU recommended a set of preferred projects to improve recharge at the existing groundwater spreading basins. This project category represents the next increment of additional groundwater recharge (imported water and/or recycled water) capable at the existing facilities. Increment 1-4 facilities would increase recharge at existing basins within the Chino Basin by an additional 15,000 AFY.	5,000	25	2	2	1	1	1	2	2	1	1	1	1	0	2	1	1	2
27	Construct New GWR Basins-Increment 1	Purchase land to construct new groundwater recharge basins in the service area to capture additional stormwater, recycled water and/or imported water for groundwater recharge. Increment 1 would provide up to an additional 2,450 AFY of recharge capacity, which is approximately one new basin at 350 AF per month for 7 months of operation.	2,450	10	2	2	2	1	1	2	2	1	1	1	1	0	2	1	1	2
28	Construct New GWR Basins-Increment 2	Purchase land to construct new groundwater recharge basins in the service area to capture additional stormwater, recycled water and/or imported water for groundwater recharge. Increment 1+2 would provide up to an additional 4,900 AFY of recharge capacity, which is approximately 2 new basins at 350 AF per month for 7 months of operation.	2,450	15	2	2	2	1	1	2	2	1	1	1	1	0	2	1	1	2
29	Construct New GWR Basins-Increment 3	Purchase land to construct new groundwater recharge basins in the service area to capture additional stormwater, recycled water and/or imported water for groundwater recharge. Increment 1-3 would provide up to an additional 7,350 AFY of recharge capacity, which is approximately 3 new basins at 350 AF per month for 7 months of operation.	2,450	20	2	2	2	1	1	2	2	1	1	1	1	0	2	1	1	2
30	Construct New GWR Basins-Increment 4	Purchase land to construct new groundwater recharge basins in the service area to capture additional stormwater, recycled water and/or imported water for groundwater recharge. Increment 1-4 would provide up to an additional 9,800 AFY of recharge capacity, which is approximately 4 new basins at 350 AF per month for 7 months of operation.	2,450	20	2	2	2	1	1	2	2	1	1	1	1	0	2	1	1	2
31	ASR wells MZ1 and MZ2	Construct aquifer storage and recovery (ASR) wells to increase improted water groundwater recharge within management zone 1 and 2. Reference projects were taken from the 2010 RMPU, Sections 6.7.2.1 and 3 for CVWD and the City of Ontario.	11,500	5	2	2	1	1	1	0	2	1	1	1	1	2	0	1	2	2
32	ASR wells MZ3	Construct aquifer storage and recovery (ASR) wells to increase imported water groundwater recharge within management zone 3. Reference projects were taken from the 2010 RMPU, Sections 6.7.2.2 for JCSD.	3,500	5	2	2	1	1	1	0	2	1	1	1	1	2	0	1	2	2
33	Maximize ASR wells	Construct other aquifer storage and recovery (ASR) wells to increase imported water groundwater recharge by 3,500 AFY within the Chino Basin during wet and dry years. Assume benefit 40% of the time (2 in 5 years). Storage to be dependent on supplemental water availability in wet years	3,500	5	2	2	1	1	1	0	2	1	1	1	1	2	0	1	1	2
34	Cadiz IW Transfer	The Cadiz project would allow for the import of unused groundwater from the remote Fenner Valley near Cadiz, California. For the purposes of the IRP, a 5,000 AFY increment of water is assumed. The Cadiz supply would be transferred and taken as SWP water into the Chino Basin.	5,000	20	2	1	1	1	1	2	2	1	1	1	1	0	1	1	1	1
35	Secure SWP IW transfer outside MWD	Imported water supply is solely from MWD via the SWP and is limited by the Agency's purchase order. Other permanent, temporary or seasonally available imported water supplies could be purchased and wheeled into the Chino Basin. The volume of water available varies depending on the source of water and timing. Supplies could be purchased from various Irrigation Districts or secured via Ag Transfer. Assume benefit 1 in 10 years	5,000	10	2	1	1	1	1	1	2	1	1	1	1	1	0	2	1	1
36	SBVMWD IW Transfer	As a SWP contractor, San Bernardino Valley MWD (SBVMWD) has a Table A allocation. This option would involve constructing an intertie between SBVMWD's imported water system. The supply would be temporary or seasonally available and could be purchased and wheeled into the Chino Basin. Assume benefit 1 in 5 years.	5,000	5	2	1	1	1	1	1	2	1	1	1	1	2	0	2	1	1
37	Ocean Desalination Exchange	This project category would involve a partnership with another water agency pursuing ocean water desalination; through in-lieu exchange, the Chino basin would obtain an agreed amount of imported water. For the purposes of the IRP, a volume of 5,000 AFY was chosen. Opportunity to invest in upcoming ocean desalination plants includes Huntington Beach, Carlsbad and West Basin.	5,000	10	2	1	1	1	1	1	2	1	1	1	1	2	0	1	1	1
38	Six Basin Water Transfer	This project would explore the idea of developing a water transfer agreement with Six Basins. One concept is to purchase imported water for recharge into Six Basins and get in return equal volume of groundwater underflow plus agreed amount of stormwater. For example, could purchase 10,000 AF of IW for exchange of 10,000 AF of groundwater plus 7,000 AF of stormwater. Assume benefit 1 in 5 years.	17,000	5	2	2	2	1	1	2	2	1	1	1	1	2	0	1	0	1
39	Expand WUE Devices	Implement additional targeted device related savings to reduce demand beyond current annual water use efficiency savings. Provide incentives and pilot programs to roll out extremely high efficient indoor fixtures and toilets. To be verified with WUEBP.	5,000	1	1	1	1	1	1	2	2	1	1	2	2	1	2	1	1	2
40	WUE - Turf Removal-Increment 1	Implement turf removal and landscape transformational programs to reduce outdoor demand. To be verified with WUEBP. Increment 1 would provide up to 5,000 AFY of savings.	5,000	1	1	1	1	1	1	2	2	1	1	2	2	1	2	1	1	2
41	WUE - Turf Removal-Increment 2	Implement turf removal and landscape transformational programs to reduce outdoor demand. To be verified with WUEBP. Increment 1+2 would provide up to 10,000 AFY of savings.	5,000	1	1	1	1	1	1	2	2	1	1	2	2	1	2	1	1	2
42	WUE - Turf Removal-Increment 3	Implement turf removal and landscape transformational programs to reduce outdoor demand. To be verified with WUEBP. Increment 1-3 would provide up to 15,000 AFY of savings.	5,000	1	1	1	1	1	1	2	2	1	1	2	2	1	2	1	1	2
43	WUE - Budget Rates-Increment 1	Implement water budget based rates for 2 member agencies (assuming 15% total savings per Agency after 3 years). To be verified with WUEBP. Increment 1 would provide up to 13,350 AFY of savings.	13,350	1	1	1	1	1	1	2	2	1	1	2	2	1	2	1	2	2

44	WUE - Budget Rates-Increment 2	Implement water budget based rates for 2 member agencies (assuming 15% total savings per Agency after 3 years). To be verified with WUEBP. Increment 1 would provide up to 26,700 AFY of savings.	13,350	1	1	1	1	1	1	2	2	1	1	2	2	1	2	1	2	2
45	WUE - Budget Rates-Increment 3	Implement water budget based rates for 2 member agencies (assuming 15% total savings per Agency after 3 years). To be verified with WUEBP. Increment 1 would provide up to 40,050 AFY of savings.	13,350	1	1	1	1	1	1	2	2	1	1	2	2	1	2	1	2	2
46	WUE- RW Demand Management-Increment 1	Implement demand management devices and programs for direct recycled water customers. Does not generate additional supply, aids in managing the supply during peak demand. Increment 1 would provide 2,500 AFY of demand management, this supply could be used for increasing direct use demands, groundwater recharge or other reuse strategy.	2,500	1	1	1	1	1	1	2	2	2	1	2	2	1	2	1	2	2
47	WUE- RW Demand Management-Increment 2	Implement demand management devices and programs for direct recycled water customers. Does not generate additional supply, aids in managing the supply during peak demand. Increment 1+2 would provide 5,000 AFY of demand management, this supply could be used for increasing direct use demands, groundwater recharge or other reuse strategy.	2,500	1	1	1	1	1	1	2	2	2	1	2	2	1	2	1	2	2
48	Dry Weather Flow Diversions	Capture and treat urban dry weather flow from Chino, Cucamonga and San Sevaine Creek into the Regional Plants. For the purposes of the IRP, a volume of 3,500 AFY was assumed as total available dry weather flow.	3,500	5	2	1	2	1	2	2	2	1	0	1	1	1	2	1	1	2
52	San Antonio Creek SW Capture	Modify existing basins along San Antonio Creek to increase stormwater capture beyond the 2013 RMPU. Increase facilities to better accommodate the "big gulp" concept. Assume benefit 1 in 5 years	1,000	10	2	1	2	1	2	2	2	1	0	1	1	2	2	1	2	2
53	Cucamonga Creek SW Capture	Modify existing basins along Cucamonga Creek to increase stormwater capture beyond the 2013 RMPU. Increase facilities to better accommodate the "big gulp" concept. Assume benefit 1 in 5 years.	2,500	10	2	1	2	1	2	2	2	1	0	1	1	2	2	1	2	2
54	Day Creek SW Capture	Modify existing basins along Day Creek to increase stormwater capture beyond the 2013 RMPU. Increase facilities to better accommodate the "big gulp" concept. Assume benefit 1 in 5 years.	2,500	10	2	1	2	1	2	2	2	1	0	1	1	2	2	1	2	2
55	San Sevaine Creek SW Capture	Modify existing basins along San Sevaine Creek to increase stormwater capture beyond the 2013 RMPU. Increase facilities to better accommodate the "big gulp" concept. Assume benefit 1 in 5 years.	2,500	10	2	1	2	1	2	2	2	1	0	1	1	2	2	1	2	2
56	Water Banking Facility	This project category would invest into the Semitropic Groundwater Storage Bank in Kern County or similar program. The Chino Basin could bank additional purchases of wet year water when these supplies are available and Chino Basin facilities are capacity limited.	5,000	10	1	1	1	1	1	2	2	1	1	1	1	1	1	2	0	1
58	Regional LID-Increment 1	Construct or modify urban development to better manage and infiltrate rainfall at the source. Projects could include bioswales and or pervious concrete installation in parking lots, street drainages. Increment 1 facilities could provide up to 5,000 AFY of recharge.	5,000	5	2	1	2	2	1	1	2	1	1	1	1	2	2	2	2	2
59	Regional LID-Increment 2	Construct or modify urban development to better manage and infiltrate rainfall at the source. Projects could include bioswales and or pervious concrete installation in parking lots, street drainages. Increment 1+2 facilities could provide up to 10,000 AFY of recharge.	5,000	5	2	1	2	2	1	1	2	1	1	1	1	2	2	2	2	2
60	Direct Potable Reuse-Increment 1	This project would construct an advanced water filtration and treatment (e.g. process treatment that combines micro or ultrafiltration) facility at a Regional Plant. The treatment process would allow the recycled water to be introduced into the potable water system. Increment 1 facility would have a capacity of 5,000 AFY.	5,000	10	1	1	1	1	1	2	2	1	1	1	1	2	0	1	2	2
61	Direct Potable Reuse-Increment 2	This project would construct an advanced water filtration and treatment (e.g. process treatment that combines micro or ultrafiltration) facility at a Regional Plant. The treatment process would allow the recycled water to be introduced into the potable water system. Increment 1+2 facility would have a capacity of 10,000 AFY.	5,000	10	1	1	1	1	1	2	2	1	1	1	1	2	0	1	2	2
62	Cucamonga Basin Improvements	This project category will identify projects that would result in additional groundwater production benefits coming into the IEUA service area from the Cucamonga Basin. Includes recharge facilities, treatment and production facilities to maximize supply coming into the Chino Basin.	2,500	5	2	2	2	1	1	2	2	1	1	1	1	0	2	1	2	2
63	Maximize Other Groundwater	This project category will identify local member agency projects that would result in additional groundwater production benefits coming into the IEUA service area outside of the Chino Basin.	5,000	5	1	1	1	1	1	2	2	1	1	1	1	1	2	2	1	2
65	RP-1 NRWS Treatment	The north Non Reclaimable Wastewater System (NRWS) discharges approx.. 3.5 MGD of brine to Los Angeles County annually. The project would construct a treatment facility to allow the Region to reuse this supply into the recycled water system. Requires plant expansion and partial reverse osmosis for blending.	3,920	9	2	1	1	1	2	2	2	1	1	1	1	2	1	1	2	2
66	WUE - Advanced Metering Technologies	Install advanced metering infrastructure (AMI) between retail meters and a utility provider. Will provide real-time data about consumption and allow customers to make informed choices about usage.	5,000	$ 3	1	1	1	1	1	2	2	1	1	2	2	1	2	1	1	2
87	Prior Stored Chino Groundwater	This category will allow supply to be taken from groundwater stored in the Chino Basin, pre 2014. It is estimated that approximately 400,000 AF of stored groundwater is available, of which 280,000 AF is made available for IEUA member agencies. This supply category will be managed on a case by case basis as selected into the Regional supply portfolios. The supply will be limited, but can be used annually or intermittent as needed.	8,400	1	0	0	1	1	1	2	2	1	1	1	1	2	2	1	2	2
88	Maximize Local Surface Water	This category of projects will construct facilities needed to capture additional local surface water. Projects to be defined by IEUA's member agencies. For example, increase surface flows off Lytle Creek in wet years. Assume benefit 3 in 5 years	1,000	1	2	1	2	1	2	2	2	1	0	1	1	2	2	1	2	2

89	Max Tier 1 MWD Imported Water-Increment 1	Maximize imported water from MWD at Tier 1 rate. Total available supply at Tier 1 rate is 93,283 AFY or cumulative purchase order maximum of 932,830 AF through December 31, 2024. Supply can be taken directly, in-lieu or for supplemental recharge. Increment 1 would allow for the purchase of an additional 7,850 AFY. Can be purchased annually or intermittently.	7,850	1	2	2	1	1	1	0	0	1	1	1	1	2	0	1	1	2
90	Max Tier 1 MWD Imported Water-Increment 2	Maximize imported water from MWD at Tier 1 rate. Total available supply at Tier 1 rate is 93,283 AFY or cumulative purchase order maximum of 932,830 AF through December 31, 2024. Supply can be taken directly, in-lieu or for supplemental recharge. Increment 1+2 would allow for the purchase of an additional 15,700 AFY. Can be purchased annually or intermittent.	7,850	1	2	2	1	1	1	0	0	1	1	1	1	2	0	1	1	2
91	Max Tier 1 MWD Imported Water-Increment 3	Maximize imported water from MWD at Tier 1 rate. Total available supply at Tier 1 rate is 93,283 AFY or cumulative purchase order maximum of 932,830 AF through December 31, 2024. Supply can be taken directly, in-lieu or for supplemental recharge. Increment 1-3 would allow for the purchase of an additional 23,550 AFY. Can be purchased annually or intermittent.	7,850	1	2	2	1	1	1	0	0	1	1	1	1	2	0	1	1	2
92	Max Tier 2 MWD Imported Water-Increment 1	Maximize imported water from MWD at Tier 2 rate. Could be taken annually or intermittent, availability pending MWD supply. Supply can be taken directly, in-lieu or for supplemental recharge. Increment 1 would allow for the purchase of an additional 5,000 AFY. Can be purchased annually or intermittent.	5,000	3	2	2	1	1	1	0	0	1	1	1	1	2	0	1	1	2
93	Max Tier 2 MWD Imported Water-Increment 2	Maximize imported water from MWD at Tier 2 rate. Could be taken annually or intermittent, availability pending MWD supply. Supply can be taken directly, in-lieu or for supplemental recharge. Increment 1+2 would allow for the purchase of an additional 10,000 AFY. Can be purchased annually or intermittent.	5,000	3	2	2	1	1	1	0	0	1	1	1	1	2	0	1	1	2
94	Max Tier 2 MWD Imported Water-Increment 3	Maximize imported water from MWD at Tier 2 rate. Could be taken annually or intermittent, availability pending MWD supply. Supply can be taken directly, in-lieu or for supplemental recharge. Increment 1-3 would allow for the purchase of an additional 15,000 AFY. Can be purchased annually or intermittently.	5,000	3	2	2	1	1	1	0	0	1	1	1	1	2	0	1	1	2
95	MWD Replenishment or discount wet year water-Increment 1	Maximize replenishment or discount wet year imported water from MWD. Availability pending MWD supply and pricing. Supply can be taken in-lieu or for supplemental recharge. Increment 1 would allow for the purchase of an additional 10,000 AFY. Can be purchased annually or intermittently. Assume benefit after 2 consecutive wet years (assume 1 in 15 years)	10,000	5	2	2	1	1	1	0	2	1	1	1	1	2	0	2	1	2
96	MWD Replenishment or discount wet year water-Increment 2	Maximize replenishment or discount wet year imported water from MWD. Availability pending MWD supply and pricing. Supply can be taken in-lieu or for supplemental recharge. Increment 1+2 would allow for the purchase of an additional 20,000 AFY. Can be purchased annually or intermittently. Assume benefit after 2 consecutive wet years (assume 1 in 15 years)	10,000	8	2	2	1	1	1	0	2	1	1	1	1	2	0	2	1	2
97	MWD Replenishment or discount wet year water-Increment 3	Maximize replenishment or discount wet year imported water from MWD. Availability pending MWD supply and pricing. Supply can be taken in-lieu or for supplemental recharge. Increment 1-3 would allow for the purchase of an additional 30,000 AFY. Can be purchased annually or intermittently. Assume benefit after 2 consecutive wet years (assume 1 in 15 years)	10,000	10	2	2	1	1	1	0	2	1	1	1	1	2	0	2	1	2
98	Watershed Wide Water Transfers	This category of projects will construct or arrange other water transfers external to the Chino Basin. For example, dry weather flow exchange of recycled water to Orange County Water District for an equivalent amount of purchased imported water. For the purposes of the IRP, it is assumed that this category of projects will not increase supply, but increases reliability and/or quality. To occur annually or intermittent. Resiliency and flexibility benefit only	-	5	1	1	1	1	1	2	2	2	1	1	1	2	2	1	2	2
99	Chino Basin Water Transfers	This category of projects will construct or arrange other water transfers within the Chino Basin. Projects to also include inter-agency interties for increased reliability. For the purposes of the IRP, it is assumed that this category of projects will not increase supply, but increases reliability. To occur annually or intermittent.	-	5	2	2	1	1	1	2	2	2	1	1	1	2	2	1	2	2
100	Reliability Production Wells	This project category will construct new production wells needed to replace lost production or under performing facilities. These projects will maintain current annual groundwater production deliveries and are intended to increase operational flexibility and reliability. Increment 1 varies in capacity and will be determined on a case by case basis as selected into each of the regional supply portfolios.	-	2	0	0	1	1	1	2	2	1	1	1	1	1	2	1	2	2

Chino Basin Groundwater - Baseline Supply Calculation

Chino Groundwater baseline Supply Calculation Sheet

GW Pumping - Available to Appropriators	Year 2040	
Developed Yield	135,000	
SARUNY	-	50% of CDA Production
Operating Safe Yield	135,000	OSY = DY - SARUNY
Ag	5,000	at 2040
Non-Ag	3,000	at 2040
Operating Safe Yield Available to Appropriators	127,000	AFY
IEUA Member Share of OSY Available to Appropriators (%)	71.9%	See below
IEUA Member Share of OSY Available to Appropriators	91,266	AFY
IEUA Member Share of SARUNY Credit (%)	57%	Based upon FY2012-13 productions
IEUA Member Share of SARUNY Credit	-	AFY
Total IEUA Member Share of GW available to Appropriators	91,266	Included SY + SARUNY credit

APPROPRIATIVE RIGHTS
(AS OF JUNE 30, 2011)

Party	Appropriative Right (Acre-Feet)	Share of Initial Operating Safe Yield (Acre-Feet)	Share of Operating Safe Yield (Percent)
City of Chino [A]	5,794.25	4,033.857	7.356
City of Chino Hills [B]	3,032.86	2,111.422	3.851
City of Norco	289.50	201.545	0.368
City of Ontario	16,337.40	11,373.816	20.742

Golden State Water Company [L]	591.05	411.476	0.750
West End Consolidated Water Company	1,361.30	947.714	1.728
San Bernardino County (Shooting Park) [M]	-	-	-
Arrowhead Mountain Springs Water Company [N]	-	-	-
City of Fontana [O]	-	-	-
Total	78,763.82	54,834.000	100.000

[A] In 1990, Chino received a portion of San Bernardino County Water Works #8 (WW#8) OSY (363.790 AF) as a result of a permanent transfer.

[B] City of Chino Hills incorporated in 1991 and assumed the responsibility for providing the public services formerly provided by WW#8. WW#8 acquired a portion of the rights of Park and Pomona Valley Water Companies in 1982.

[C] CCWD acquired the rights to Etiwanda Water Company (upon dissolution) in 1996. CCWD changed its name to CVWD in 2004.

[D] JCSD acquired the rights of Mira Loma Water Company in 1979 (779.340 AF OSY), Feldspar Gardens in 1986 (47.543AF OSY) and Mutual Water Company of Glen Avon Heights in 1997 (467.374 AF OSY).

[E] MVCWD changed its name to MVWD in 1980. In 1990, MVWD received 675.616 AF of WW#8 OSY as a result of a permanent transfer.

[F] WSBCWD changed its name to WVWD in 2003.

[G] In FY 01-02, 5.000 AF OSY was reassigned: 1.000 AF to FWC and 4.000 AF to the Nicholson Trust.

[H] FWC intervened in 1985 and was assigned 1.000 AF OSY as a result of a permanent transfer of water rights from FUWC.

[I] Los Serranos intervened into the Appropriative Pool in 1990 with 0.000 AF OSY, and it was later determined that they are not within the Basin.

[J] Niagara Bottling intervened in FY 02-03 with 0.000 AF OSY.

[K] Nicholson Trust intervened in FY 01-02 and was assigned 4.000 AF OSY as a result of a permanent transfer of water rights from FUWC.

[L] GSWC permanently transferred 623.500 AF OSY to Park Water Company in 1980. Park Water Co was acquired by WW#8 which was subsequently acquired by the City of Chino Hills. SCWC changed its name to GSWC in 2005.

[M] San Bernardino County Prado Tiro (now known as Prado Shooting Park) was involuntarily reassigned to the Appropriative Pool from the Agricultural Pool in 1986.

[N] Arrowhead intervened in 1992 with 0.000 AF OSY.

[O] City of Fontana intervened in 1998 with 0.000 AF OSY.

2015 Integrated Water Resources Plan: Mitigation Actions

IEUA Drought Contingency Plan

Appendix 5:

Full IRP Technical Committee Identified Project List

ID	Project Name	Description	AF yield	Years to "wet water" yield	Increased groundwater in storage?	Increases water level in critical GW management zones?	Increased stormwater capture/recharge?	Increased permeability or natural infiltration for	Provide additional recycled water?	Reduce Dependence on imported water from MWD during dry	Increase local water supplies?	Emergency local supply redundancy?	Decrease reliance on local surface water during dry years?	Requires conservation in existing development?	Requires demand management in new development?	Reduce TDS and/or nitrates in GW?	Decrease net energy consumption?	Increase capacity of wet year water ("big	Eligible for grant funding?	Technical feasibility/ease of
1	Groundwater Treatment (Rehab)-Increment 1	This project category will rehabilitate an existing groundwater production wells decommissioned due to water quality concerns. It is assumed that additional pumping would be limited by the volume of recharge occurring (over operating safe yield). Increased well operation could supplement annual demands or intermittent to help offset losses in another water supply. Increment 1 will provide up to 5,000 AFY of production.	5,000	2	0	0	1	1	1	2	2	1	1	1	1	2	2	1	2	2
2	Groundwater Treatment (Rehab)-Increment 2	This project category will rehabilitate an existing groundwater production wells decommissioned due to water quality concerns. It is assumed that additional pumping would be limited by the volume of recharge occurring (over operating safe yield). Increased well operation could supplement annual demands or intermittent to help offset losses in another water supply. Increment 1 + 2 will provide up to 10,000 AFY of production.	5,000	2	0	0	1	1	1	2	2	1	1	1	1	2	2	1	2	2
3	Groundwater Treatment (new)-Increment 1	This project category will construct a new groundwater production well and treatment facility to address water quality concerns. It is assumed that additional pumping would be limited by the volume of recharge occurring (over operating safe yield). Increased well operation could supplement annual demands or intermittent to help offset losses in another water supply. Increment 1 will provide up to 5,000 AFY of production.	5,000	2	0	0	1	1	1	2	2	1	1	1	1	2	2	1	1	2
4	Groundwater Treatment (new)-Increment 2	This project category will construct a new groundwater production well and treatment facility to address water quality concerns. It is assumed that additional pumping would be limited by the volume of recharge occurring (over operating safe yield). Increased well operation could supplement annual demands or intermittent to help offset losses in another water supply. Increment 1 + 2 will provide up to 10,000 AFY of production.	5,000	2	0	0	1	1	1	2	2	1	1	1	1	2	2	1	1	2
5	Production Wells-Increment 1	With increasing groundwater recharge to the Chino Basin, new production wells may need to be constructed to recover the additional groundwater. It is assumed that additional pumping would be limited by the volume of recharge occurring (over operating safe yield). Well operation could supplement annual demands or intermittent to help offset losses in another water supply. Increment 1 will provide up to 5,000 AFY of production	5,000	2	0	0	1	1	1	2	2	1	1	1	1	1	2	1	2	2
6	Production Wells-Increment 2	With increasing groundwater recharge to the Chino Basin, new production wells may need to be constructed to recover the additional groundwater. It is assumed that additional pumping would be limited by the volume of recharge occurring (over operating safe yield). Well operation could supplement annual demands or intermittent to help offset losses in another water supply. Increment 1+2 will provide up to 10,000 AFY of production	5,000	2	0	0	1	1	1	2	2	1	1	1	1	1	2	1	2	2
7	Production Wells-Increment 3	With increasing groundwater recharge to the Chino Basin, new production wells may need to be constructed to recover the additional groundwater. It is assumed that additional pumping would be limited by the volume of recharge occurring (over operating safe yield). Well operation could supplement annual demands or intermittent to help offset losses in another water supply. Increment 1-3 will provide up to 15,000 AFY of production	5,000	2	0	0	1	1	1	2	2	1	1	1	1	1	2	1	1	2
8	Production Wells-Increment 4	With increasing groundwater recharge to the Chino Basin, new production wells may need to be constructed to recover the additional groundwater. It is assumed that additional pumping would be limited by the volume of recharge occurring (over operating safe yield). Well operation could supplement annual demands or intermittent to help offset losses in another water supply. Increment 1-4 will provide up to 20,000 AFY of production	5,000	2	0	0	1	1	1	2	2	1	1	1	1	1	2	1	1	2
9	WRCRWA RW Intertie	The Western Riverside County Regional Wastewater Authority (WRCRWA) Plant intertie would allow for the delivery of recycled water from the WRCRWA Plant to be used in the IEUA southern service area. This would also allow additional recycled water to be delivered into the northern service area groundwater recharge basins by reducing the demand from the RP-1 930 pressure zone pump station. Intertie would occur within the 800/930 Pressure Zones.	4,500	10	2	1	1	1	2	2	2	2	1	1	1	1	2	1	1	1
10	Rialto RW Intertie	The Rialto intertie project would allow for delivery of recycled water from the Rialto WWTP to be used in the IEUA service area. The intertie could occur near the RP-3 groundwater recharge basins. This concept could involve the Inland Valley Pipeline, LLC (IVP) to convey water between Rialto WWTP and IEUA's recycled water distribution system. Supply could be used for direct, GWR or other reuse strategy.	4,500	10	2	2	1	1	2	2	2	2	1	1	1	1	2	1	1	1
11	Pomona RW Exchange/Transfer	The City of Pomona does not currently use all of the treated effluent from the Pomona WRP. One concept would involve partnering to develop and expand their recycled water facilities in exchange for an agreed amount of their Chino Basin groundwater right. Could include other supply transfer agreement such as reclaimable waste and/or groundwater.	2,500	10	2	2	1	1	1	2	2	1	1	1	1	1	2	1	1	1
12	RP-1 RW Injection-Increment 1	This project would construct an advanced water filtration (e.g. process treatment that combines micro or ultrafiltration) facility at RP-1 to further treat tertiary effluent to allow the water to be injected directly into Chino Basin. The sizing of the facility and the volume to be produced will be determined as part of the portfolio development process. Increment 1 facility would be sized for 2,500 AFY.	2,500	9	2	1	1	1	1	2	2	1	1	1	1	2	0	1	2	2

13	RP-1 RW Injection-Increment 2	This project would construct an advanced water filtration (e.g. process treatment that combines micro or ultrafiltration) facility at RP-1 to further treat tertiary effluent to allow the water to be injected directly into Chino Basin. The sizing of the facility and the volume to be produced will be determined as part of the portfolio development process. Increment 1+2 facility would be sized for 5,000 AFY.	2,500	9	2	1	1	1	1	2	2	1	1	1	1	2	0	1	1	2
14	RP-1 RW Injection-Increment 3	This project would construct an advanced water filtration (e.g. process treatment that combines micro or ultrafiltration) facility at RP-1 to further treat tertiary effluent to allow the water to be injected directly into Chino Basin. The sizing of the facility and the volume to be produced will be determined as part of the portfolio development process. Increment 1-3 facility would be sized for 7,500 AFY.	2,500	9	2	1	1	1	1	2	2	1	1	1	1	2	0	1	1	2
15	Satellite RW Injection-Increment 1	This project category would construct a satellite (outside of RP-1) wastewater treatment plant with advanced water filtration (e.g. process treatment that combines micro or ultrafiltration) to allow the water to be injected directly into Chino Basin. The location, sizing and volume to be produced will be determined as part of the portfolio development process. Increment 1 facility, or facilities would have a capacity of 2,500 AFY.	2,500	5	2	2	1	1	1	2	2	1	1	1	1	2	0	1	2	2
16	Satellite RW Injection-Increment 2	This project category would construct a satellite (outside of RP-1) wastewater treatment plant with advanced water filtration (e.g. process treatment that combines micro or ultrafiltration) to allow the water to be injected directly into Chino Basin. The location, sizing and volume to be produced will be determined as part of the portfolio development process. Increment 1+2 facility, or facilities would have a capacity of 5,000 AFY.	2,500	5	2	2	1	1	1	2	2	1	1	1	1	2	0	1	1	2
17	Satellite RW Injection-Increment 3	This project category would construct a satellite (outside of RP-1) wastewater treatment plant with advanced water filtration (e.g. process treatment that combines micro or ultrafiltration) to allow the water to be injected directly into Chino Basin. The location, sizing and volume to be produced will be determined as part of the portfolio development process. Increment 1-3 facility, or facilities would have a capacity of 7,500 AFY.	2,500	5	2	2	1	1	1	2	2	1	1	1	1	2	0	1	1	2
18	Desalter Recovery Improvement	The existing Chino Basin I Desalter (CD-1) recovers approximately 75 percent of water. Improvements could be done to increase recovery to approximately 90 percent. This water would be conveyed through the existing potable water system.	1,500	3	1	1	1	1	1	2	2	1	1	1	1	2	1	1	1	2
19	RW Direct Use Expansion-Increment 1	IEUA developed a new Recycled Water Program Strategy concurrent with the IRP. This project category will be used to determine the potential interest in expanding the direct use system beyond the Agency's Ten Year CIP. Includes the reuse of regional wastewater supply, approximately 83,000 AFY by 2035 and potential recycled water interties. Increment 1 facilities would increase direct use beyond baseline supply by 5,000 AFY.	5,000	15	1	1	1	1	1	2	2	1	1	1	1	0	2	1	2	2
20	RW Direct Use Expansion-Increment 2	IEUA developed a new Recycled Water Program Strategy concurrent with the IRP. This project category will be used to determine the potential interest in expanding the direct use system beyond the Agency's Ten Year CIP. Includes the reuse of regional wastewater supply, approximately 83,000 AFY by 2035 and potential recycled water interties. Increment 1+2 facilities would increase direct use beyond baseline supply by 10,000 AFY.	5,000	20	1	1	1	1	1	2	2	1	1	1	1	0	2	1	1	2
21	RW Direct Use Expansion-Increment 3	IEUA developed a new Recycled Water Program Strategy concurrent with the IRP. This project category will be used to determine the potential interest in expanding the direct use system beyond the Agency's Ten Year CIP. Includes the reuse of regional wastewater supply, approximately 83,000 AFY by 2035 and potential recycled water interties. Increment 1-3 facilities would increase direct use beyond baseline supply by 15,000 AFY.	5,000	25	1	1	1	1	1	2	2	1	1	1	1	0	2	1	1	2
22	RW Direct Use Expansion-Increment 4	IEUA developed a new Recycled Water Program Strategy concurrent with the IRP. This project category will be used to determine the potential interest in expanding the direct use system beyond the Agency's Ten Year CIP. Includes the reuse of regional wastewater supply, approximately 83,000 AFY by 2035 and potential recycled water interties. Increment 1-4 facilities would increase direct use beyond baseline supply by 20,000 AFY.	5,000	25	1	1	1	1	1	2	2	1	1	1	1	0	2	1	1	2
23	Existing GWR Basin Improvements beyond RMPU-Increment 1	The 2013 Chino Basin RMPU recommended a set of preferred projects to improve recharge at the existing groundwater spreading basins. This project category represents the next increment of additional groundwater recharge (imported water and/or recycled water) capable at the existing facilities. Increment 1 facilities would increase recharge at existing basins within the Chino Basin by an additional 2,500 AFY.	2,500	15	2	2	1	1	1	2	2	1	1	1	1	0	2	1	2	2
24	Existing GWR Basin Improvements beyond RMPU-Increment 2	The 2013 Chino Basin RMPU recommended a set of preferred projects to improve recharge at the existing groundwater spreading basins. This project category represents the next increment of additional groundwater recharge (imported water and/or recycled water) capable at the existing facilities. Increment 1+2 facilities would increase recharge at existing basins within the Chino Basin by an additional 5,000 AFY.	2,500	20	2	2	1	1	1	2	2	1	1	1	1	0	2	1	2	2
25	Existing GWR Basin Improvements beyond RMPU-Increment 3	The 2013 Chino Basin RMPU recommended a set of preferred projects to improve recharge at the existing groundwater spreading basins. This project category represents the next increment of additional groundwater recharge (imported water and/or recycled water) capable at the existing facilities. Increment 1-3 facilities would increase recharge at existing basins within the Chino Basin by an additional 10,000 AFY.	5,000	25	2	2	1	1	1	2	2	1	1	1	1	0	2	1	1	2

26	Existing GWR Basin Improvements beyond RMPU-Increment 4	The 2013 Chino Basin RMPU recommended a set of preferred projects to improve recharge at the existing groundwater spreading basins. This project category represents the next increment of additional groundwater recharge (imported water and/or recycled water) capable at the existing facilities. Increment 1-4 facilities would increase recharge at existing basins within the Chino Basin by an additional 15,000 AFY.	5,000	25	2	2	1	1	1	2	2	1	1	1	1	0	2	1	1	2
27	Construct New GWR Basins-Increment 1	Purchase land to construct new groundwater recharge basins in the service area to capture additional stormwater, recycled water and/or imported water for groundwater recharge. Increment 1 would provide up to an additional 2,450 AFY of recharge capacity, which is approximately one new basin at 350 AF per month for 7 months of operation.	2,450	10	2	2	2	1	1	2	2	1	1	1	1	0	2	1	1	2
28	Construct New GWR Basins-Increment 2	Purchase land to construct new groundwater recharge basins in the service area to capture additional stormwater, recycled water and/or imported water for groundwater recharge. Increment 1+2 would provide up to an additional 4,900 AFY of recharge capacity, which is approximately 2 new basins at 350 AF per month for 7 months of operation.	2,450	15	2	2	2	1	1	2	2	1	1	1	1	0	2	1	1	2
29	Construct New GWR Basins-Increment 3	Purchase land to construct new groundwater recharge basins in the service area to capture additional stormwater, recycled water and/or imported water for groundwater recharge. Increment 1-3 would provide up to an additional 7,350 AFY of recharge capacity, which is approximately 3 new basins at 350 AF per month for 7 months of operation.	2,450	20	2	2	2	1	1	2	2	1	1	1	1	0	2	1	1	2
30	Construct New GWR Basins-Increment 4	Purchase land to construct new groundwater recharge basins in the service area to capture additional stormwater, recycled water and/or imported water for groundwater recharge. Increment 1-4 would provide up to an additional 9,800 AFY of recharge capacity, which is approximately 4 new basins at 350 AF per month for 7 months of operation.	2,450	20	2	2	2	1	1	2	2	1	1	1	1	0	2	1	1	2
31	ASR wells MZ1 and MZ2	Construct aquifer storage and recovery (ASR) wells to increase improted water groundwater recharge within management zone 1 and 2. Reference projects were taken from the 2010 RMPU, Sections 6.7.2.1 and 3 for CVWD and the City of Ontario.	11,500	5	2	2	1	1	1	0	2	1	1	1	1	2	0	1	2	2
32	ASR wells MZ3	Construct aquifer storage and recovery (ASR) wells to increase imported water groundwater recharge within management zone 3. Reference projects were taken from the 2010 RMPU, Sections 6.7.2.2 for JCSD.	3,500	5	2	2	1	1	1	0	2	1	1	1	1	2	0	1	2	2
33	Maximize ASR wells	Construct other aquifer storage and recovery (ASR) wells to increase imported water groundwater recharge by 3,500 AFY within the Chino Basin during wet and dry years. Assume benefit 40% of the time (2 in 5 years). Storage to be dependent on supplemental water availability in wet years	3,500	5	2	2	1	1	1	0	2	1	1	1	1	2	0	1	1	2
34	Cadiz IW Transfer	The Cadiz project would allow for the import of unused groundwater from the remote Fenner Valley near Cadiz, California. For the purposes of the IRP, a 5,000 AFY increment of water is assumed. The Cadiz supply would be transferred and taken as SWP water into the Chino Basin.	5,000	20	2	1	1	1	1	2	2	1	1	1	1	0	1	1	1	1
35	Secure SWP IW transfer outside MWD	Imported water supply is solely from MWD via the SWP and is limited by the Agency's purchase order. Other permanent, temporary or seasonally available imported water supplies could be purchased and wheeled into the Chino Basin. The volume of water available varies depending on the source of water and timing. Supplies could be purchased from various Irrigation Districts or secured via Ag Transfer. Assume benefit 1 in 10 years	5,000	10	2	1	1	1	1	1	2	1	1	1	1	1	0	2	1	1
36	SBVMWD IW Transfer	As a SWP contractor, San Bernardino Valley MWD (SBVMWD) has a Table A allocation. This option would involve constructing an intertie between SBVMWD's imported water system. The supply would be temporary or seasonally available and could be purchased and wheeled into the Chino Basin. Assume benefit 1 in 5 years.	5,000	5	2	1	1	1	1	1	2	1	1	1	1	2	0	2	1	1
37	Ocean Desalination Exchange	This project category would involve a partnership with another water agency pursuing ocean water desalination; through in-lieu exchange, the Chino basin would obtain an agreed amount of imported water. For the purposes of the IRP, a volume of 5,000 AFY was chosen. Opportunity to invest in upcoming ocean desalination plants includes Huntington Beach, Carlsbad and West Basin.	5,000	10	2	1	1	1	1	1	2	1	1	1	1	2	0	1	1	1
38	Six Basin Water Transfer	This project would explore the idea of developing a water transfer agreement with Six Basins. One concept is to purchase imported water for recharge into Six Basins and get in return equal volume of groundwater underflow plus agreed amount of stormwater. For example, could purchase 10,000 AF of IW for exchange of 10,000 AF of groundwater plus 7,000 AF of stormwater. Assume benefit 1 in 5 years.	17,000	5	2	2	2	1	1	2	2	1	1	1	1	2	0	1	0	1
39	Expand WUE Devices	Implement additional targeted device related savings to reduce demand beyond current annual water use efficiency savings. Provide incentives and pilot programs to roll out extremely high efficient indoor fixtures and toilets. To be verified with WUEBP.	5,000	1	1	1	1	1	1	2	2	1	1	2	2	1	2	1	1	2
40	WUE - Turf Removal-Increment 1	Implement turf removal and landscape transformational programs to reduce outdoor demand. To be verified with WUEBP. Increment 1 would provide up to 5,000 AFY of savings.	5,000	1	1	1	1	1	1	2	2	1	1	2	2	1	2	1	1	2
41	WUE - Turf Removal-Increment 2	Implement turf removal and landscape transformational programs to reduce outdoor demand. To be verified with WUEBP. Increment 1+2 would provide up to 10,000 AFY of savings.	5,000	1	1	1	1	1	1	2	2	1	1	2	2	1	2	1	1	2
42	WUE - Turf Removal-Increment 3	Implement turf removal and landscape transformational programs to reduce outdoor demand. To be verified with WUEBP. Increment 1-3 would provide up to 15,000 AFY of savings.	5,000	1	1	1	1	1	1	2	2	1	1	2	2	1	2	1	1	2
43	WUE - Budget Rates-Increment 1	Implement water budget based rates for 2 member agencies (assuming 15% total savings per Agency after 3 years). To be verified with WUEBP. Increment 1 would provide up to 13,350 AFY of savings.	13,350	1	1	1	1	1	1	2	2	1	1	2	2	1	2	1	2	2

44	WUE - Budget Rates-Increment 2	Implement water budget based rates for 2 member agencies (assuming 15% total savings per Agency after 3 years). To be verified with WUEBP. Increment 1 would provide up to 26,700 AFY of savings.	13,350	1	1	1	1	1	1	2	2	1	1	2	2	1	2	1	2	2
45	WUE - Budget Rates-Increment 3	Implement water budget based rates for 2 member agencies (assuming 15% total savings per Agency after 3 years). To be verified with WUEBP. Increment 1 would provide up to 40,050 AFY of savings.	13,350	1	1	1	1	1	1	2	2	1	1	2	2	1	2	1	2	2
46	WUE- RW Demand Management-Increment 1	Implement demand management devices and programs for direct recycled water customers. Does not generate additional supply, aids in managing the supply during peak demand. Increment 1 would provide 2,500 AFY of demand management, this supply could be used for increasing direct use demands, groundwater recharge or other reuse strategy.	2,500	1	1	1	1	1	1	2	2	2	1	2	2	1	2	1	2	2
47	WUE- RW Demand Management-Increment 2	Implement demand management devices and programs for direct recycled water customers. Does not generate additional supply, aids in managing the supply during peak demand. Increment 1+2 would provide 5,000 AFY of demand management, this supply could be used for increasing direct use demands, groundwater recharge or other reuse strategy.	2,500	1	1	1	1	1	1	2	2	2	1	2	2	1	2	1	2	2
48	Dry Weather Flow Diversions	Capture and treat urban dry weather flow from Chino, Cucamonga and San Sevaine Creek into the Regional Plants. For the purposes of the IRP, a volume of 3,500 AFY was assumed as total available dry weather flow.	3,500	5	2	1	2	1	2	2	2	1	0	1	1	1	2	1	1	2
52	San Antonio Creek SW Capture	Modify existing basins along San Antonio Creek to increase stormwater capture beyond the 2013 RMPU. Increase facilities to better accommodate the "big gulp" concept. Assume benefit 1 in 5 years	1,000	10	2	1	2	1	2	2	2	1	0	1	1	2	2	1	2	2
53	Cucamonga Creek SW Capture	Modify existing basins along Cucamonga Creek to increase stormwater capture beyond the 2013 RMPU. Increase facilities to better accommodate the "big gulp" concept. Assume benefit 1 in 5 years.	2,500	10	2	1	2	1	2	2	2	1	0	1	1	2	2	1	2	2
54	Day Creek SW Capture	Modify existing basins along Day Creek to increase stormwater capture beyond the 2013 RMPU. Increase facilities to better accommodate the "big gulp" concept. Assume benefit 1 in 5 years.	2,500	10	2	1	2	1	2	2	2	1	0	1	1	2	2	1	2	2
55	San Sevaine Creek SW Capture	Modify existing basins along San Sevaine Creek to increase stormwater capture beyond the 2013 RMPU. Increase facilities to better accommodate the "big gulp" concept. Assume benefit 1 in 5 years.	2,500	10	2	1	2	1	2	2	2	1	0	1	1	2	2	1	2	2
56	Water Banking Facility	This project category would invest into the Semitropic Groundwater Storage Bank in Kern County or similar program. The Chino Basin could bank additional purchases of wet year water when these supplies are available and Chino Basin facilities are capacity limited.	5,000	10	1	1	1	1	1	2	2	1	1	1	1	1	1	2	0	1
58	Regional LID-Increment 1	Construct or modify urban development to better manage and infiltrate rainfall at the source. Projects could include bioswales and or pervious concrete installation in parking lots, street drainages. Increment 1 facilities could provide up to 5,000 AFY of recharge.	5,000	5	2	1	2	2	1	1	2	1	1	1	1	2	2	2	2	2
59	Regional LID-Increment 2	Construct or modify urban development to better manage and infiltrate rainfall at the source. Projects could include bioswales and or pervious concrete installation in parking lots, street drainages. Increment 1+2 facilities could provide up to 10,000 AFY of recharge.	5,000	5	2	1	2	2	1	1	2	1	1	1	1	2	2	2	2	2
60	Direct Potable Reuse-Increment 1	This project would construct an advanced water filtration and treatment (e.g. process treatment that combines micro or ultrafiltration) facility at a Regional Plant. The treatment process would allow the recycled water to be introduced into the potable water system. Increment 1 facility would have a capacity of 5,000 AFY.	5,000	10	1	1	1	1	1	2	2	1	1	1	1	2	0	1	2	2
61	Direct Potable Reuse-Increment 2	This project would construct an advanced water filtration and treatment (e.g. process treatment that combines micro or ultrafiltration) facility at a Regional Plant. The treatment process would allow the recycled water to be introduced into the potable water system. Increment 1+2 facility would have a capacity of 10,000 AFY.	5,000	10	1	1	1	1	1	2	2	1	1	1	1	2	0	1	2	2
62	Cucamonga Basin Improvements	This project category will identify projects that would result in additional groundwater production benefits coming into the IEUA service area from the Cucamonga Basin. Includes recharge facilities, treatment and production facilities to maximize supply coming into the Chino Basin.	2,500	5	2	2	2	1	1	2	2	1	1	1	1	0	2	1	2	2
63	Maximize Other Groundwater	This project category will identify local member agency projects that would result in additional groundwater production benefits coming into the IEUA service area outside of the Chino Basin.	5,000	5	1	1	1	1	1	2	2	1	1	1	1	1	2	2	1	2
65	RP-1 NRWS Treatment	The north Non Reclaimable Wastewater System (NRWS) discharges approx.. 3.5 MGD of brine to Los Angeles County annually. The project would construct a treatment facility to allow the Region to reuse this supply into the recycled water system. Requires plant expansion and partial reverse osmosis for blending.	3,920	9	2	1	1	1	2	2	2	1	1	1	1	2	1	1	2	2
66	WUE - Advanced Metering Technologies	Install advanced metering infrastructure (AMI) between retail meters and a utility provider. Will provide real-time data about consumption and allow customers to make informed choices about usage.	5,000	$ 3	1	1	1	1	1	2	2	1	1	2	2	1	2	1	1	2
87	Prior Stored Chino Groundwater	This category will allow supply to be taken from groundwater stored in the Chino Basin, pre 2014. It is estimated that approximately 400,000 AF of stored groundwater is available, of which 280,000 AF is made available for IEUA member agencies. This supply category will be managed on a case by case basis as selected into the Regional supply portfolios. The supply will be limited, but can be used annually or intermittent as needed.	8,400	1	0	0	1	1	1	2	2	1	1	1	1	2	2	1	2	2
88	Maximize Local Surface Water	This category of projects will construct facilities needed to capture additional local surface water. Projects to be defined by IEUA's member agencies. For example, increase surface flows off Lytle Creek in wet years. Assume benefit 3 in 5 years	1,000	1	2	1	2	1	2	2	2	1	0	1	1	2	2	1	2	2

89	Max Tier 1 MWD Imported Water-Increment 1	Maximize imported water from MWD at Tier 1 rate. Total available supply at Tier 1 rate is 93,283 AFY or cumulative purchase order maximum of 932,830 AF through December 31, 2024. Supply can be taken directly, in-lieu or for supplemental recharge. Increment 1 would allow for the purchase of an additional 7,850 AFY. Can be purchased annually or intermittently.	7,850	1	2	2	1	1	1	0	0	1	1	1	1	2	0	1	1	2
90	Max Tier 1 MWD Imported Water-Increment 2	Maximize imported water from MWD at Tier 1 rate. Total available supply at Tier 1 rate is 93,283 AFY or cumulative purchase order maximum of 932,830 AF through December 31, 2024. Supply can be taken directly, in-lieu or for supplemental recharge. Increment 1+2 would allow for the purchase of an additional 15,700 AFY. Can be purchased annually or intermittent.	7,850	1	2	2	1	1	1	0	0	1	1	1	1	2	0	1	1	2
91	Max Tier 1 MWD Imported Water-Increment 3	Maximize imported water from MWD at Tier 1 rate. Total available supply at Tier 1 rate is 93,283 AFY or cumulative purchase order maximum of 932,830 AF through December 31, 2024. Supply can be taken directly, in-lieu or for supplemental recharge. Increment 1-3 would allow for the purchase of an additional 23,550 AFY. Can be purchased annually or intermittent.	7,850	1	2	2	1	1	1	0	0	1	1	1	1	2	0	1	1	2
92	Max Tier 2 MWD Imported Water-Increment 1	Maximize imported water from MWD at Tier 2 rate. Could be taken annually or intermittent, availability pending MWD supply. Supply can be taken directly, in-lieu or for supplemental recharge. Increment 1 would allow for the purchase of an additional 5,000 AFY. Can be purchased annually or intermittent.	5,000	3	2	2	1	1	1	0	0	1	1	1	1	2	0	1	1	2
93	Max Tier 2 MWD Imported Water-Increment 2	Maximize imported water from MWD at Tier 2 rate. Could be taken annually or intermittent, availability pending MWD supply. Supply can be taken directly, in-lieu or for supplemental recharge. Increment 1+2 would allow for the purchase of an additional 10,000 AFY. Can be purchased annually or intermittent.	5,000	3	2	2	1	1	1	0	0	1	1	1	1	2	0	1	1	2
94	Max Tier 2 MWD Imported Water-Increment 3	Maximize imported water from MWD at Tier 2 rate. Could be taken annually or intermittent, availability pending MWD supply. Supply can be taken directly, in-lieu or for supplemental recharge. Increment 1-3 would allow for the purchase of an additional 15,000 AFY. Can be purchased annually or intermittenty.	5,000	3	2	2	1	1	1	0	0	1	1	1	1	2	0	1	1	2
95	MWD Replenishment or discount wet year water-Increment 1	Maximize replenishment or discount wet year imported water from MWD. Availability pending MWD supply and pricing. Supply can be taken in-lieu or for supplemental recharge. Increment 1 would allow for the purchase of an additional 10,000 AFY. Can be purchased annually or intermittently. Assume benefit after 2 consecutive wet years (assume 1 in 15 years)	10,000	5	2	2	1	1	1	0	2	1	1	1	1	2	0	2	1	2
96	MWD Replenishment or discount wet year water-Increment 2	Maximize replenishment or discount wet year imported water from MWD. Availability pending MWD supply and pricing. Supply can be taken in-lieu or for supplemental recharge. Increment 1+2 would allow for the purchase of an additional 20,000 AFY. Can be purchased annually or intermittently. Assume benefit after 2 consecutive wet years (assume 1 in 15 years)	10,000	8	2	2	1	1	1	0	2	1	1	1	1	2	0	2	1	2
97	MWD Replenishment or discount wet year water-Increment 3	Maximize replenishment or discount wet year imported water from MWD. Availability pending MWD supply and pricing. Supply can be taken in-lieu or for supplemental recharge. Increment 1-3 would allow for the purchase of an additional 30,000 AFY. Can be purchased annually or intermittently. Assume benefit after 2 consecutive wet years (assume 1 in 15 years)	10,000	10	2	2	1	1	1	0	2	1	1	1	1	2	0	2	1	2
98	Watershed Wide Water Transfers	This category of projects will construct or arrange other water transfers external to the Chino Basin. For example, dry weather flow exchange of recycled water to Orange County Water District for an equivalent amount of purchased imported water. For the purposes of the IRP, it is assumed that this category of projects will not increase supply, but increases reliability and/or quality. To occur annually or intermittent. Resiliency and flexibility benefit only	-	5	1	1	1	1	1	2	2	2	1	1	1	2	2	1	2	2
99	Chino Basin Water Transfers	This category of projects will construct or arrange other water transfers within the Chino Basin. Projects to also include inter-agency interties for increased reliability. For the purposes of the IRP, it is assumed that this category of projects will not increase supply, but increases reliability. To occur annually or intermittent.	-	5	2	2	1	1	1	2	2	2	1	1	1	2	2	1	2	2
100	Reliability Production Wells	This project category will construct new production wells needed to replace lost production or under performing facilities. These projects will maintain current annual groundwater production deliveries and are intended to increase operational flexibility and reliability. Increment 1 varies in capacity and will be determined on a case by case basis as selected into each of the regional supply portfolios.	-	2	0	0	1	1	1	2	2	1	1	1	1	1	2	1	2	2

Appendix E: Response Action Program Cut Sheets

IEUA Drought Contingency Plan

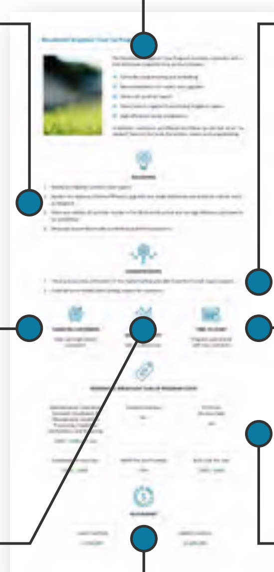
Table of Contents

Guide to the Program Write-Ups

IEUA has selected seven customer programs to be offered during drought conditions. Each program is detailed in an individual write-up contained in this section.

The sections contained in each write-up are explained in the diagram below:

DESCRIPTION
Provides a basic overview of the program, the measures, and delivery mechanisms



REASONING
Overviews the market need being met and reasons for this particular program design

CONSIDERATIONS
Provides awareness of additional program issues or circumstances that may impact the program

TARGETED CUSTOMERS
Identifies the customer groups targeted for program participation

TIME TO START
The anticipated time to develop and start-up operations for the program

POTENTIAL ANNUAL ACTIVITY
The expected number of customer participants or product installations per year

PROGRAM COSTS
Program costs are broken down into six categories: Administration & Operational costs; Product Incentive or rebate; IEUA's cost per Acre-foot (cost/the lifetime water savings); Estimated Cost per Unit (total costs per property); MAAP per unit (potential Member Agency Administered Program funding from MWD), and; IEUA cost per unit (Estimated Cost per Unit – MAAP per unit)

IEUA BUDGET
Identifies the overall annual cost to IEUA for the program at both a low participation and high participation levels

Turf Replacement Program

The Turf Replacement Program encourages customers to remove high water-consuming turf and replace it with alternative solutions such as low water-using, regionally appropriate plants and surfaces that allow for ground water infiltration and elimination of runoff. Qualifying applicants are eligible to receive $3 per square foot of turf removed with a maximum incentive of 5,000 square feet for residential customers and 50,000 square feet for commercial customers. Eligible projects must have:

- Three plants per 100 square feet of area transformed
- No hardscape within the transformed area, except permeable hardscape
- A stormwater retention feature
- Replacement or modification of overhead spray sprinklers

For reference, the historical program activity of square feet removed is listed below.

	Residential	Commercial	Total
FY 14/15	119,130	1,136,334	1,255,464
FY 15/16	1,596,789	3,337,120	4,933,909
FY 16/17	255,091	637,916	893,007

REASONING

1. There are hundreds of thousands of square feet of irrigated turf in the IEUA territory.
1. Replacing turf with regionally appropriate plants aids in transforming the market. In a recent analysis done by Western MWD, for every customer replacing their turf, another customer did so without an incentive.
2. Provides long term savings- Current studies have shown that savings increase after the initial plant stabilization period and persist over 10 years or more.

CONSIDERATIONS

1. Turf replacement has an extremely high cost per acre-foot.
3. The market acceptance is low during non-drought times.
4. There are numerous customer barriers: costs, concerns about the new look, and lack of ability to execute projects.
5. Contractors are not interested in projects smaller than 1,000 sf.

TARGETED CUSTOMERS	POTENTIAL ANNUAL ACTIVITY	TIME TO START
All customers with live turf	500,000 – 5 Million SF	Currently operational

TURF REPLACEMENT PROGRAM COSTS

Administration, Contractor Outreach, Enrollment & Management, Incentive Processing, Inspection Verifications, and Reporting	Product Incentive	IEUA Cost Per Acre-foot
Covered by Metropolitan through regional vendor	**$3 per square foot**	**$769** **($ per sf)**
Estimated Per Unit Cost	MAAP Per Unit Funding	IEUA Cost Per Unit
$3 per sf	**$2.00 (regional rebate)**	**$1 per sf**

IEUA BUDGET

Lower Incentive	Higher Incentive
$500,000	**$5,000,000**

Residential Irrigation Tune Up Program

The Residential Irrigation Tune Program provides customers with a free landscape irrigation tune-up that includes:

- Controller programming and scheduling
- Recommendation for repairs and upgrades
- Valve and sprinkler repairs
- Minor lateral irrigation line and drip irrigation repairs
- High efficiency nozzle installations

In addition, customers are offered one follow-up site visit on an "as needed" basis to fine-tune the system, repairs and programming.

REASONING

1. Nearly all irrigation systems need repairs.
6. Repairs are necessary before efficiency upgrades are made otherwise new products will not work as designed.
7. There are millions of sprinkler nozzles in the IEUA territory that are not high efficiency and need to be retrofitted.
8. Measures are professionally installed by qualified contractors.

CONSIDERATIONS

1. There are very few contractors in the market willing and able to perform small repair projects.
9. Could be some liability with making repairs for customers.

TARGETED CUSTOMERS	POTENTIAL ANNUAL ACTIVITY	TIME TO START
High use single family customers	500 – 2,500 homes	Program operational with one contractor

RESIDENTIAL IRRIGATION TUNE UP PROGRAM COSTS

Administration, Contractor Outreach, Enrollment & Management, Incentive Processing, Inspection Verifications, and Reporting	Product Incentive	IEUA Cost Per Acre-foot
$300 - $400 per site	**NA**	**NA**
Estimated Per Unit Cost	MAAP Per Unit Funding	IEUA Cost Per Unit
$300 - $400	**TBD**	**$300 - $400**

IEUA BUDGET

Lower Incentive	Higher Incentive
$150,000	**$1,000,000**

Smart Irrigation Direct Installation

DESCRIPTION

The Smart Irrigation Direct Installation Program offers the installation of smart irrigation devices, potentially free to the customer. The Program could offer:

- Smart cloud-based controllers
- High efficiency sprinkler nozzles
- Wireless flow sensors

In order to maximize water savings, a qualification consideration could be that customers must have one acre or more of irrigated area or water usage of over 450,000 gallons per year per household. The Program could be designed with a customer co-pay, which would boost cost effectiveness. The inclusion of nozzle installations adds tremendous costs and could be eliminated if the budget does not allow it.

REASONING

1. Top water users and large landscape properties offer maximum water savings due to the expansive volume of acreage of irrigated lawns and gardens. In addition, over one-acre sites provide additional MAAP funding.
2. Single family properties with irrigated area have controllers and spray heads, but most do not have the latest smart irrigation technologies.
3. The smart irrigation package includes proven technologies that will be appealing to customers.
4. Addition of flow sensors will provide the ability to detect abnormal water use and alert property owners via text or email.
5. Measures will be professionally installed by contractors ensuring quality installations and programming.
6. Direct installation contractors typically meet installation goals on schedule due to proactive sales activities.

CONSIDERATIONS

1. High cost to provide direct installations.
2. Sometimes customers do not buy into new measures, specifically programming of the controller and they will override efficiency schedule.
3. Could be some liability with providing product and installation.

TARGETED CUSTOMERS	POTENTIAL ANNUAL ACTIVITY	TIME TO START
Single-family, multi-family, commercial 1 acre or larger	1,000 – 5,000 properties	6 – 8 months

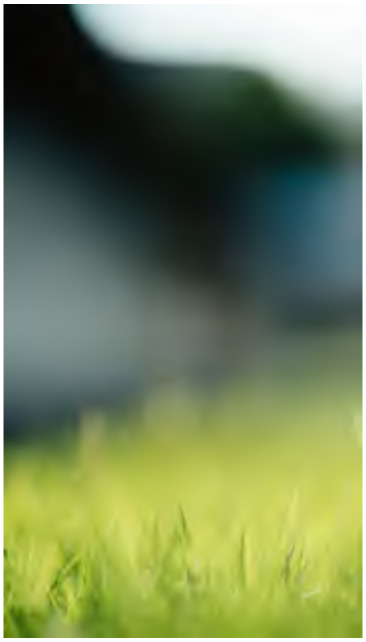
SMART IRRIGATION DIRECT INSTALLATION PROGRAM COSTS

Administration, Contractor Outreach, Enrollment & Management, Incentive Processing, Inspection Verifications, and Reporting **$400**	Product Incentive **Free to customer**	IEUA Cost Per Acre-foot **$327**
Estimated Per Unit Cost **$1,550**	MAAP Per Unit Funding **$600**	IEUA Cost Per Unit **$950**

IEUA BUDGET

Lower Incentive	Higher Incentive
$950,000	**$4,750,000**

School Smart Irrigation Direct Installation



DESCRIPTION

Schools use a tremendous amount of water for irrigation, specifically for watering their lawn areas. These lawns are frequently used for student sports and recreation and therefore not candidates for turf replacement. The School Smart Irrigation Program would offer local schools free installation of smart irrigation devices. Measures to include:

- Pressure regulating spray heads
- High efficiency sprinkler nozzles
- Flow sensors and master valves (if practical)
- Smart cloud-based controllers (if practical)

If cost prohibitive flow sensors, master valves and smart controllers can be eliminated.

REASONING

1. Schools have large areas of functional lawn area, used for sports and recreation.

2. School properties typically have irrigation systems with old malfunctioning equipment. Much of the time the spray heads are broken, clogged, below grade or too high.

3. Most schools have limited budgets and resources to purchase and install irrigation equipment.

4. The program addition of flow sensors and master valves eliminates water waste due to leaks by shutting off the valve. In addition, the flow sensing data provides information on actual water usage.

5. Smart cloud-based controllers can provide and share water use information.

6. Improved irrigation efficiency in schools can significantly reduce their utility costs.

7. The program provides opportunity for schools to demonstrate leadership and educate students on water use efficiency.

CONSIDERATIONS

1. High cost to provide direct installations.
2. School personnel may override programming of the controller.
3. Could be some liability with providing product and installation.

TARGETED CUSTOMERS	POTENTIAL ANNUAL ACTIVITY	TIME TO START
Public schools	Schools	6 – 8 months

SCHOOL SMART IRRIGATION DIRECT INSTALLATION PROGRAM COSTS

Administration, Contractor Outreach, Enrollment & Management, Incentive Processing, Inspection Verifications, and Reporting $	Product Incentive **Free to customer**	IEUA Cost Per Acre-foot $
Estimated Per Unit Cost $	MAAP Per Unit Funding $	IEUA Cost Per Unit $

IEUA BUDGET

Lower Incentive	Higher Incentive
$	$

Qualified Contractor Irrigation Incentive Program

DESCRIPTION

Program will allow customers to receive a comprehensive package of innovative and proven irrigation technologies from qualified contractors, for the following discounted prices:

- Smart controllers $35 - $50 per station
- High efficiency sprinkler nozzles **$6 - $10 per nozzle**
- Flow sensors with master valves **$60 - $100 per sensor**
- Drip irrigation **$0.40 - $0.60**

Eligible contractors would include: QWEL, CLCA and IA certified firms. Customers would be responsible for installation costs.

Targeted properties would include all customer segments (commercial, multi-family and residential) with one acre or more of irrigated area, with a program focus on commercial and HOA common areas.

REASONING

1. Large landscape properties offer maximum water savings due to the expansive acreage of irrigated lawns and gardens.
2. MF, CII and SF properties with irrigated area have irrigation controllers and spray heads, but most do not have the latest water-efficient smart irrigation technologies.
3. The smart irrigation package includes proven technologies that will be of interest to customers and their contractors.
4. Measures will be professionally installed by qualified contractors.

CONSIDERATIONS

1. In order to achieve activity goals, it will be necessary to offer the higher incentive making the program more costly.

2. Enlisting and managing contractors will take expert resources and add significant costs to the program.

TARGETED CUSTOMERS	POTENTIAL ANNUAL ACTIVITY	TIME TO START
All customer segments with one acre or more of irrigated area	250 – 1,000 homes	6 months

QUALIFIED CONTRACTOR IRRIGATION INCENTIVE PROGRAM COSTS

Administration, Contractor Outreach, Enrollment & Management, Incentive Processing, Inspection Verifications, and Reporting **$300 per property**	Product Incentive (24-station controller, 150 nozzles, 46 sf of drip, 25 flow sensor/master valve) **Average of $1,809 per property** **(assumes full MAAP funding)**	IEUA Cost Per Acre-foot **$31 - $450**
Estimated Per Unit Cost **$2,109 - $3,227**	MAAP Per Unit Funding **$1,809**	IEUA Cost Per Unit **$300 - $1,418**

IEUA BUDGET

Lower Incentive	Higher Incentive
$75,000 - $300,000	**$354,500 - $1,418,000**

FreeSprinklerNozzles.com

The FreeSprinklerNozzles.com Program provides participating water agencies with a full-service approach to distribution of high efficiency sprinkler nozzles to their residential and commercial customers while requiring only minimal staffing. Nozzles are provided free to customers. Customer are responsible for installation.

With eight years of successful implementation, program management is looking to overhaul the FreeSprinklerNozzles.com program. The goal is for the new program to be a 100% online fulfilment program.

The new program would include an online application that would utilize aerial imagery to map a customer's landscaped area and irrigation system. The customer would use the tool to measure their irrigated area and note head locations. The system would automatically generate a nozzle inventory which would be sent to the irrigation equipment fulfilment center electronically. The nozzles would then be shipped to the customer.

REASONING

1. Nearly all properties in IEUA's territory with irrigated area have spray heads that can be retrofitted with efficient nozzles – there are literally millions of nozzles in this market available to be upgraded.
2. The product is easy to install and inexpensive.
3. The program offers a turnkey approach requiring minimal resources from IEUA or its member agencies.

CONSIDERATIONS

1. With a small device that many customers store in their garage until needed, a higher percentage of customers may not install the nozzles.

TARGETED CUSTOMERS	POTENTIAL ANNUAL ACTIVITY	TIME TO START
All customers with irrigated area & spray heads	50,000 – 200,000	Expected launch date of December 2019

FREESPRINKLERNOZZLES.COM PROGRAM COSTS

Administration, Contractor Outreach, Enrollment & Management, Incentive Processing, Inspection Verifications, and Reporting **Estimated $2 per nozzle**	Product Incentive **Free to customer**	IEUA Cost Per Acre-foot **$92 - $450**
Estimated Per Unit Cost **$5 - $6**	MAAP Per Unit Funding **$2 - $4**	IEUA Cost Per Unit **$2 - $4**

IEUA BUDGET

Lower Incentive	Higher Incentive
$100,000	**$800,000**

Leak Detection Incentive

DESCRIPTION

Household leaks can result in thousands of gallons of wasted water and potential property damage.

Smart leak detector devices can now monitor use, detect anomalies and alert homeowners of potential leaks. Some devices can even shut off use, mitigating water damage.

The Leak Detection Incentive would offer customers a rebate for purchase of an approved monitoring and leak detection device. There are currently five viable products on the market including Flume, Buoy, Flo, Phyn and Saya. Some devices require tapping into the existing plumbing system and may require a licensed plumber for installation, while others simply attach to the customer's water meter.

The water savings are unknown at the time and cost for product with installation ranges from $200 - $700+. The program could also offer free installation for customers with high use or could be an incentive offered to the manufacturer. The manufacturer would offer an incentive off the purchase price and bill IEUA for those properties.

REASONING

1. Many homes have leaks, currently industry estimates 10%.
2. Most leaks go undetected and customers are not aware for months until they get their bill and many times not even then.
3. Repairing water damage caused by leaks can cost thousands of dollars for a typical homeowner.
4. Providing customers with data on their water use gives them the necessary information and motivation to make efficiency changes.
5. Several water agencies have incentive and installation programs including: Southern Nevada Water Authority, Jurupa Community Services District, Contra Costa Water District, Rainbow Municipal Water District, and San Antonio Water System.

CONSIDERATIONS

1. Savings are unknown.
2. If water agency already has AMI, service is duplicative.
3. Program not applicable to all customers, must target customers with potential leaks and ones that value monitoring data.
4. Customer still has to fix leaks to secure savings.

TARGETED CUSTOMERS Single-family homes, potentially in high pressure areas or with a significant increase in use	**POTENTIAL ANNUAL ACTIVITY** 500 – 1,000 homes	**TIME TO START** 4 months

LEAK DETECTION INCENTIVE PROGRAM COSTS

Administration, Contractor Outreach, Enrollment & Management, Incentive Processing, Inspection Verifications, and Reporting **$25 per home**	Product Incentive **$100 per home**	IEUA Cost Per Acre-foot **TBD**
Estimated Per Unit Cost **$125**	MAAP Per Unit Funding **TBD**	IEUA Cost Per Unit **$125**

IEUA BUDGET

Lower Incentive	Higher Incentive
$62,500	**$125,000**

WEFlex Fund

DESCRIPTION

Recognizing that the future is unknowable, IEUA understands that unforeseen marketing and water savings opportunities may present themselves at some point during a drought cycle. For this reason, the WEFlex Fund was created to allow IEUA to quickly respond and fund a new, creative approach.

The program will offer IEUA's retail agencies funds for locallyadministered activities. The budget will be allocated to each agency based upon the water agencies size (or water sales). An agency could use the funds for local activities such as water waste enforcement and education or recycled water hook up and permit fees. Other programs or services could be funded through WE Flex Fund, if approved by the drought response committee.

An agency will submit a description of the local activity, estimated costs and potential benefits or results. When accepted, IEUA will provide the funds.

REASONING

1. Should an effective new technology, marketing/promotional initiative, or delivery mechanism become available, IUEA does not want an agency to be limited to the pre-selected list of programs.
2. The program allows for retail agencies to choose a program or service that best serves their needs and those of their customers.
3. Typically, approval and funding of new initiatives take significant time to work their way through the management hierarchy. The WE Flex Fund will allow for an expedited process to implement new tactics.

CONSIDERATIONS

1. In order to achieve activity goals, it will be necessary to offer the higher incentive making the program more costly.
2. Enlisting and managing contractors will take expert resources and add significant costs to the program.

TARGETED CUSTOMERS	**POTENTIAL ANNUAL ACTIVITY**	**TIME TO START**
All customer segments	NA	Immediate

WEFLEX PROGRAM COSTS

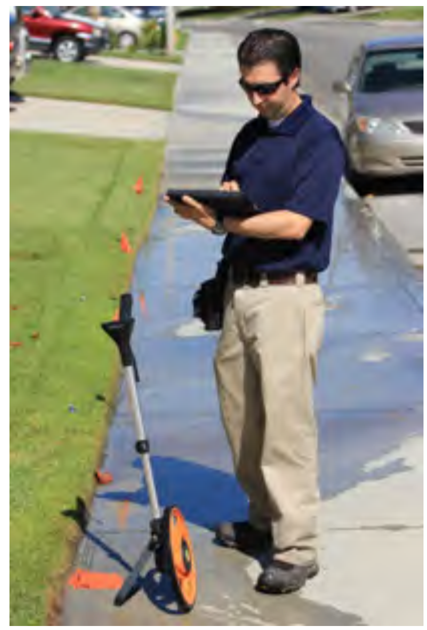
Administration, Contractor Outreach, Enrollment & Management, Incentive Processing, Inspection Verifications, and Reporting **TBD**	Product Incentive (24-station controller, 150 nozzles, 46 sf of drip, 25 flow sensor/master valve) **TBD**	IEUA Cost Per Acre-foot **TBD**
Estimated Per Unit Cost **TBD**	MAAP Per Unit Funding **TBD**	IEUA Cost Per Unit **TBD**

Services Offered

In addition to Programs, three Support Services are offered to provide customers with knowledge and information about water efficient landscaping. These Services are:

1. Landscape Surveys
2. Landscape Workshops
3. Landscape Design Services

Landscape Surveys



Administered by the Chino Basin Water Conservation District (CBWCD), in partnership with IEUA and the member agencies, the Landscape Survey Program offers customers a free evaluation of their landscape and irrigation system.

The survey includes:

- A complete evaluation of the customer's irrigation system
- Determination of the landscape's water needs
- Accurate profile of the property's water consumption
- Generation of a water budget based on the local evapotranspiration and irrigated landscape area

Customer's also receive:

- Water saving tips
- Recommendations on how to improve overall efficiency of your irrigation system
- Rebate opportunities

In order to ensure water savings, it is recommended that the surveys also include follow up to verify any recommendations have been implemented and assist customers in making the upgrades and receiving the incentives.

Landscape Workshops

The landscape classes offered through the IEUA service areas are FREE of charge. The descriptions below provide a basic overview of the topics covered.

Drought Tolerant Plants - This class provides information on a variety of water efficient plants that fit both our climate and landscape design. The instructor will discuss native and other California friendly plants, the benefits they provide to your landscape, and when and how to plant them.

Landscape Design - This class provides residents with the initial basics on how to develop a landscape that combines both beauty and environmental benefits to their home. Both preparation and design techniques will be discussed.

Water Efficient Irrigation Systems - This class teaches residents the importance of using water wisely and how an efficient irrigation system enables them to play their part in efficient water use. Overhead sprinklers, drip systems and irrigation controllers will be discussed.

Turf Removal - This class is specialized to instruct residents on the proper techniques to remove turf and replace it with a water efficient landscape.

Composting, Fertilizer, & Maintenance - This class teaches residents about compost, fertilizer and their correct usage to help plants flourish. Participants will also learn about the correct maintenance to ensure growth for their plants.

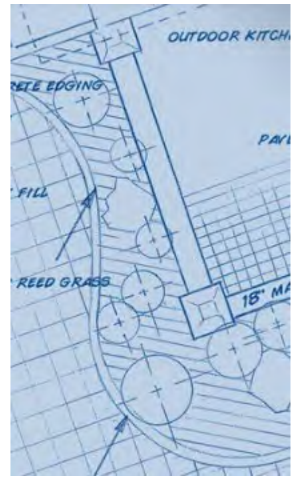
How the Drought Affects Your Water Timer - This class will help residents understand the watering restrictions and how to program their controller to align with their retail agency's outdoor watering restrictions.

Composting, Water Management, & Pest Control - This class provides instruction on composting, proper watering techniques, and integrated pest management. Participants will learn how often and how much to water plants, how to identify what can be used to compost, how to properly apply compost, and how to sustainably control pests.

Drought, El Nino, & What to do with Your Landscape - This class gives residents tips and tricks on how to maintain their landscape during transitioning seasons and weather changes.

Mini Class - Comprehensive four-hour class covering Landscape design basics, California friendly & native plants, landscape sprinkler systems, and planting and maintenance.

Landscape Design Services



Through a collaboration between CBWCD, IEUA and its member agencies, customers are offered landscape design services free of charge. This service has a market value of approximately $500.

Participants are required to attend a two-hour "What You Need to Know Before Your Landscape Transformation" class before they become eligible to register for the Landscape Design Assistance Program. The class is focused on providing all the information most people need to be successful with a turf replacement project, whether they are doing the work themselves or hiring a contractor.

Due to program demand, customers are provided design services for EITHER their front yard OR back yard. If a customer completes the first project, they can receive additional design services.

A CBMWD staff member consults with participants for approximately 1.5 - 2 hours in person at the Waterwise Community Center. At the appointment, customers discuss goals for their landscape area and then work with staff to create a computer-generated design for the landscape project.

After the consultation meeting, CBWCD staff finish the design, create a plant identification key and a custom plant list with the names and information about each plant selected for the designed landscape. Customers are also provided with a list of resources including sources of plants and other landscape materials.

SUBJECT: 2020 Urban Water Management Plan Update

Dear Agency Representative:

The Inland Empire Utilities Agency (IEUA) is undertaking the review, update, and revision of its Urban Water Management Plan (UWMP). The Urban Water Management Planning Act requires every urban water supplier of a certain size to prepare and adopt an UWMP at least once every five years. The UWMP is a planning document in which water suppliers evaluate and compare their water supply and reliability to their existing and projected demands. IEUA is in the process of preparing the 2020 UWMP Update.

As an urban water supplier, the IEUA is required pursuant to Section 10620(d)(3) of the California Water Code to coordinate with water management agencies, relevant public agencies, and other water suppliers regarding the preparation of the UWMP. Pursuant to Section 10621(b) of the California Water Code, the IEUA will be reviewing the UWMP and will make amendments or changes, as appropriate. Based on the IEUA's current schedule, we expect to have a draft available for public review by April 2021, at which point your agency will receive notification that the draft UWMP is available for public review and comment.

The IEUA invites you to submit written comments in anticipation of the development of our 2020 UWMP Update within the next 30 days to IEUA. If your agency would like to learn more about the UWMP, please feel free to contact me at 909.993.1698 or jaguilar@ieua.org.

Sincerely,

J. Aguilar

April 2021 60-Day Notification Letter to City, County and Others Within IEUA Service Area

NOTICE OF PUBLIC HEARING
BY THE BOARD OF DIRECTORS OF THE INLAND EMPIRE UTILITIES AGENCY*
TO ADOPT THE 2020 URBAN WATER MANAGEMENT PLAN (UWMP),
ADDENDUM OF APPENDIX G TO THE 2015 UWMP,
AND WATER SHORTAGE CONTINGENCY PLAN
SAN BERNARDINO COUNTY, STATE OF CALIFORNIA

NOTICE IS HEREBY GIVEN that the Board of Directors of the Inland Empire Utilities Agency intends to hold a public hearing for adoption of the 2020 Urban Water Management Plan (UWMP), Addendum of Appendix G to the 2015 UWMP, and Water Shortage Contingency Plan.

NOTICE IS FURTHER GIVEN that said public hearing will be held on the following date and time for the purpose of hearing any and all public testimony on the above-stated issue.

DATE: Wednesday, June 16, 2021 – 10:00 a.m.

The meeting will be accessible via teleconference at:
Phone Number: (415) 856-9169 / Conference ID: 811 284 110#

In the effort to prevent the spread of COVID-19, until further notice, the Inland Empire Utilities Agency will hold all Board and Committee meetings by video and audio conference. As of the posting/publication of this notice, it is anticipated that the public hearing will be conducted virtually by video and audio conference. (Please visit www.ieua.org for the most up-to-date information regarding meeting participation.) There will be no public location available to attend the meeting; all interested persons are invited to participate in the public hearing and provide comments regarding the proposed 2020 UWMP, Addendum of Appendix G to the 2015 UWMP, and Water Shortage Contingency Plan by calling into the number provided above. The public may also view the meeting live through the Agency's website at www.ieua.org. Oral statements will be heard, but for the accuracy of the record all important testimony should be submitted in writing. Written comments may be emailed to the Board Secretary/Office Manager Denise Garzaro at dgarzaro@ieua.org no later than 24 hours prior to the scheduled meeting time. Comments submitted in advance will be read into the record during the hearing.

NOTICE IS FURTHER GIVEN that the 2020 UWMP, Addendum of Appendix G to the 2015 UWMP, and Water Shortage Contingency Plan will be available on the Agency's website at www.ieua.org and via hard-copy upon request in Spring of 2021, no less than two weeks prior to the public hearing. All interested parties are noticed and invited to submit comments and consult with the Agency regarding its forthcoming 2020 UWMP, Addendum of Appendix G to the 2015 UWMP, and Water Shortage Contingency Plan to the Strategic Planning and Resources Department, attention Joshua Aguilar at jaguilar@ieua.org. For additional information regarding the 2020 UWMP, Addendum of Appendix G to the 2015 UWMP, and Water Shortage Contingency Plan, please contact Senior Engineer, Joshua Aguilar at (909) 993-1694.

SUBJECT: Posting of the 2020 Urban Water Management Plan, Addendum of Appendix G to the 2015 UWMP, and 2020 Water Shortage Contingency Plan

Dear Agency Representative:

The Inland Empire Utilities Agency (IEUA) is inviting public review and comment on its Draft 2020 Urban Water Management Plan (UWMP). The Plan includes an updated Addendum of Appendix G to the 2015 UWMP and 2020 Water Shortage Contingency Plan (WSCP).

In compliance with California Water Code (§10610-10656, §10608 and §10632) the UWMP and WSCP are required to contain detailed evaluations of water supplies necessary to reliably meet demands of the California Water Code to coordinate with water management agencies, relevant public agencies, and other water suppliers regarding the preparation of the UWMP and other plans.

All plan documents are now available on IEUA's website here: https://www.ieua.org/read-our-reports/other-reports/.

Comments must be received no later than **5:00 p.m. Monday, May 24, 2021** and sent to the attention of Joshua Aguilar, 909.993.1698 or jaguilar@ieua.org.

If you or your agency would like more information on IEUA's UWMP, Addendum, or WSCP, please contact me.

Sincerely,

Joshua Aguilar

WSCP Appendix E

Resolution of Adoption of UWMP, WSCP, and Addendum

RESOLUTION NO.2021-6-10

A RESOLUTION OF THE BOARD OF DIRECTORS OF THE INLAND EMPIRE UTILITIES AGENCY (IEUA), SAN BERNARDINO COUNTY, CALIFORNIA, ADOPTING THE 2020 URBAN WATER MANAGEMENT PLAN, 2020 WATER SHORTAGE CONTINGENCY PLAN, AND APPENDIX G AS AN ADDENDUM TO THE 2015 URBAN WATER MANAGEMENT PLAN

Whereas, the California Legislature enacted Assembly Bill 797, (Water Code Section 10610 et seq., known as the Urban Water Management Planning Act) during the 1983-1984 Regular Session, and as amended subsequently, which mandates that every urban water supplier providing water for municipal purposes either directly or indirectly to more than 3,000 customers or supplying more than 3,000 acre-feet of water annually, prepare an Urban Water Management Plan at least once every five years; and

Whereas, the Urban Water Management Planning Act requires the preparation and adoption of a Water Shortage Contingency Plan, in accordance with prescribes requirements; and

Whereas, the Urban Water Management Planning Act specifies the requirements and procedures for amending and adopting such Urban Water Management Plans; and

Whereas, the Inland Empire Utilities Agency* is a wholesale supplier of water for 242-square miles in the western portion of San Bernardino; and

Whereas, pursuant to Section 10620 of the Urban Water Management Planning Act, the Inland Empire Utilities Agency has prepared the 2020 Urban Water Management Plan, 2020 Water Shortage Contingency Plan, and Appendix G as an addendum to the 2015 Urban Water Management Plan; and

Whereas, the Board of Directors of the Inland Empire Utilities Agency has duly reviewed, discussed, and considered the 2020 Urban Water Management Plan, 2020 Water Shortage Contingency Plan, and Appendix G as an addendum to the 2015 Urban Water Management Plan.

NOW, THEREFORE, BE IT RESOLVED, DETERMINED AND ORDERED BY THE INLAND EMPIRE UTILITIES AGENCY AS FOLLOWS:

Section 1. The 2020 Urban Water Management Plan is hereby adopted; and

Section 2. The 2020 Water Shortage Contingency Plan is hereby adopted; and

Section 3. The addendum of Appendix G to the 2015 Urban Water Management Plan is hereby adopted; and

Section 4. The General Manager is hereby authorized to file an electronic copy of the 2020 Urban Water Management Plan, 2020 Water Shortage Contingency Plan, and Appendix G to the 2015 Urban Water Management Plan with the State Department of Water Resources within 30 days following its adoption and no later than July 1, 2021.

Section 5. The General Manager is hereby authorized to file a CD or hardcopy of aforementioned plans with the California State Library no later than 30 days after its adoption.

Section 6. The General Manager is hereby authorized to submit an electronic copy or a CD or hardcopy of the adopted aforementioned plans to any city or county in which the suppliers provide water no later than 30 days after its adoption.

Section 7. The General Manager is hereby authorized and directed to implement the adopted aforementioned plans, including recommendations to the Board of Directors regarding necessary procedures, rules, and regulations in an effort to carry out effective and equitable water programs.

Section 8. The Resolution shall take effect upon adoption.

ADOPTED this 16th day of June 2021.

Jasmin A. Hall, President of the Inland Empire Utilities Agency* and the Board of Directors thereof

ATTEST:

Steven J. Elie, Secretary/Treasurer of the Inland Empire Utilities Agency* and of the Board of Directors thereof

The undersigned certifies that this is a true copy as on file in the permanent records of the Agency. This stamp must be in purple ink to constitute a certified copy.
Inland Empire Utilities Agency*
A Municipal Water Agency
By Denise Gy Date 6/16/2021

STATE OF CALIFORNIA)
)SS
COUNTY OF)
SAN BERNARDINO

I, Steven J. Elie, Secretary of the Inland Empire Utilities Agency*,

DO HEREBY CERTIFY that the foregoing Resolution being No. 2021-6-10, was adopted at a regular Board Meeting on June 16, 2021, of said Agency by the following vote:

AYES:	Camacho, Elie, Hall, Hofer, Tule
NOES:	None
ABSTAIN:	None
ABSENT:	None

Steven J. Elie, Secretary/Treasurer of the
Inland Empire Utilities Agency* and of
the Board of Directors thereof

DWR Planning Tool and Standardized Tables

Submittal Table 2-2: Plan Identification			
Select Only One	Type of Plan		Name of RUWMP or Regional Alliance *if applicable* (select from drop down list)
☑	**Individual UWMP**		
	☐	Water Supplier is also a member of a RUWMP	
	☐	Water Supplier is also a member of a Regional Alliance	
☐	**Regional Urban Water Management Plan (RUWMP)**		
NOTES:			

Submittal Table 2-3: Supplier Identification	
Type of Supplier (select one or both)	
☑	Supplier is a wholesaler
☐	Supplier is a retailer
Fiscal or Calendar Year (select one)	
☐	UWMP Tables are in calendar years
☑	UWMP Tables are in fiscal years
If using fiscal years provide month and date that the fiscal year begins (mm/dd)	
7/1	
Units of measure used in UWMP * (select from drop down)	
Unit	AF
**** Units of measure (AF, CCF, MG)** must remain consistent throughout the UWMP as reported in Table 2-3.*	
NOTES:	

Submittal Table 2-4 Wholesale: Water Supplier Information Exchange (select one)	
☑	Supplier has informed more than 10 other water suppliers of water supplies available in accordance with Water Code Section 10631. Completion of the table below is optional. If not completed, include a list of the water suppliers that were informed.
	Provide page number for location of the list.
☐	Supplier has informed 10 or fewer other water suppliers of water supplies available in accordance with Water Code Section 10631. **Complete the table below.**

Water Supplier Name
Add additional rows as needed
Chino Basin Water Master
Chino Basin Desalter Authority
City of Chino
City of Chino Hills
Cucamonga Valley Water District
Fontana Water Company
Local Agency Formation Commission for San Bernardino County
City of Montclair
Monte Vista Water District
Metropolitan Water District
City of Ontario
City of Rancho Cucamonga
Santa Ana Regional Water Quality Control Board
San Antonio Water Company
Santa Ana Watershed Project Authority
San Bernardino County Planning Department
Three Valleys Municipal Water District
City of Upland
Water Facilities Authority
West Valley Water District
NOTES:

Submittal Table 3-1 Wholesale: Population - Current and Projected						
Population Served	2020	2025	2030	2035	2040	2045*(opt)*
	906,046	945,849	987,401	1,031,771	1,074,773	1,119,568
NOTES: Population projections calculated using the 2020 Southern California Association of Government's population forecast.						

Submittal Table 4-1 Wholesale: Demands for Potable and Non-Potable Water - Actual			
Use Type	2020 Actual		
Drop down list May select each use multiple times These are the only use types that will be recognized by the WUE data online submittal tool	Additional Description (as needed)	Level of Treatment When Delivered Drop down list	Volume*
Add additional rows as needed			
Sales to other agencies	MWD Imported Water	Raw Water	66,438
		TOTAL	66,438
**** Units of measure (AF, CCF, MG)*** *must remain consistent throughout the UWMP as reported in Table 2-3.*			
NOTES: Volume values from IEUA Annual Water Use Database.			

Submittal Table 4-2 Wholesale: Use for Potable and Raw Water - Projected						
Use Type	Additional Description (as needed)	**Projected Water Use *** Report To the Extent that Records are Available				
Drop down list May select each use multiple times These are the only Use Types that will be recognized by the WUEdata online submittal tool.		2025	2030	2035	2040	2045 (opt)
Add additional rows as needed						
Sales to other agencies	Imported Water from MWD provided to Retail Agencies	77,416	79,630	81,974	84,021	84,065
TOTAL		77,416	79,630	81,974	84,021	84,065

**** Units of measure (AF, CCF, MG)*** *must remain consistent throughout the UWMP as reported in Table 2-3.*

NOTES:

Submittal Table 4-3 Wholesale: Total Water Use (Potable and Non-Potable)						
	2020	2025	2030	2035	2040	2045 (opt)
Potable and Raw Water From Tables 4-1W and 4-2W	66,438	77,416	79,630	81,974	84,021	84,065
Recycled Water Demand* From Table 6-4W	30,496	39,300	41,297	42,162	44,191	44,691
TOTAL WATER DEMAND	96,934	116,716	120,927	124,136	128,212	128,756

**Recycled water demand fields will be blank until Table 6-4 is complete.*

NOTES: 2020 Values from FY 19/20 Recycled Water Annual Report and FY 19/20 Annual Water Use Report. Projected potable and raw water volumes is the sum of each retail agency's expected use of imported water from IEUA. Recycled water projections are the sum of direct use from member agencies and groundwater recharge projections from IEUA.

Submittal Table 5-1 Baselines and Targets Summary
From SB X7-7 Verification Form
Retail Supplier or Regional Alliance Only

Baseline Period	Start Year *	End Year *	Average Baseline GPCD*	Confirmed 2020 Target*
10-15 year	1995 - 1999	2004 - 2008	245	193
5 Year	2003 - 2005	2007 - 2009	227	

**All cells in this table should be populated manually from the supplier's SBX7-7 Verification Form and reported in Gallons per Capita per Day (GPCD)*

NOTES:

Submittal Table 5-2: 2020 Compliance From SB X7-7 2020 Compliance Form *Retail Supplier or Regional Alliance Only*				
2020 GPCD			2020 Confirmed Target GPCD*	Did Supplier Achieve Targeted Reduction for 2020? Y/N
Actual 2020 GPCD*	2020 TOTAL Adjustments*	Adjusted 2020 GPCD* *(Adjusted if applicable)*		
171	0	0	193	Yes
**All cells in this table should be populated manually from the supplier's SBX7-7 2020 Compliance Form and reported in Gallons per Capita per Day (GPCD)*				
NOTES:				

Submittal Table 6-1 Wholesale: Groundwater Volume Pumped						
☑	Supplier does not pump groundwater. The supplier will not complete the table below.					
☐	All or part of the groundwater described below is desalinated.					
Groundwater Type Drop Down List	Location or Basin Name	2016*	2017*	2018*	2019*	2020*
Add additional rows as needed						
	TOTAL	0	0	0	0	0
**** Units of measure (AF, CCF, MG)*** *must remain consistent throughout the UWMP as reported in Table 2-3.*						
NOTES:						

Submittal Table 6-3 Wholesale: Wastewater Treatment and Discharge Within Service Area in 2020											
☐	Wholesale Supplier neither distributes nor provides supplemental treatment to recycled water. The Supplier will not complete the table below.										
Wastewater Treatment Plant Name	Discharge Location Name or Identifier	Discharge Location Description	Wastewater Discharge ID Number *(optional)* [2]	Method of Disposal ***Drop down list***	Does This Plant Treat Wastewater Generated Outside the Service Area? ***Drop down list***	Treatment Level ***Drop down list***	**2020 volumes** [1]				
							Wastewater Treated	Discharged Treated Wastewater	Recycled Within Service Area	Recycled Outside of Service Area	Instream Flow Permit Requirement
Add additional rows as needed											
RP-1	DP-001	Prado Lake	8332818001	Lake outfall	Yes	Tertiary	26,932	25,889	30,495	0	0
	DP-002	Cucamonga Creek	8332818001	River or creek outfall	Yes	Tertiary				0	0
RP-4	DP-002	Cucamonga Creek	8332818001	River or creek outfall	Yes	Tertiary	10,718			0	0
RP-5	DP-003	Chino Creek	8332818001	River or creek outfall	Yes	Tertiary	9,699			0	0
CCWRF	DP-004	Chino Creek	8332818001	River or creek outfall	Yes	Tertiary	9,035			0	0
						Total	56,384	25,889	30,495	0	0

[1] **Units of measure (AF, CCF, MG)** must remain consistent throughout the UWMP as reported in Table 2-3.

[2] If the **Wastewater Discharge ID Number** is not available to the UWMP preparer, access the SWRCB CIWQS regulated facility website at https://ciwqs.waterboards.ca.gov/ciwqs/readOnly/CiwqsReportServlet?inCommand=reset&reportName=RegulatedFacility

NOTES:

Submittal Table 6-4 Wholesale: Current and Projected Retailers Provided Recycled Water Within Service Area							
☐	Recycled water is not directly treated or distributed by the Supplier. The Supplier will not complete the table below.						
Name of Receiving Supplier or Direct Use by Wholesaler	Level of Treatment *Drop down list*	2020*	2025*	2030*	2035*	2040*	2045* *(opt)*
Add additional rows as needed							
Direct Use	Tertiary	17,115	22,880	24,877	25,742	27,771	28,271
Groundwater Recharge	Tertiary	13,381	16,420	16,420	16,420	16,420	16,420
	Total	30,496	39,300	41,297	42,162	44,191	44,691
*** Units of measure (AF, CCF, MG)** must remain consistent throughout the UWMP as reported in Table 2-3.							
NOTES: 2020 value from FY 19/20 Recycled Water Annual Report. Direct use projected values from retail agencies. No projections were made for 2045, so the projected volume is set equal to 2040. Groundwater recharge projections from IEUA projections based on groundwater recharge annual report data.							

Submittal Table 6-5 Wholesale: 2015 UWMP Recycled Water Use Projection Compared to 2020 Actual		
☐	Recycled water was not used or distributed by the supplier in 2015, nor projected for use or distribution in 2020. The wholesale supplier will not complete the table below.	
Name of Receiving Supplier or Direct Use by Wholesaler	2015 Projection for 2020*	2020 Actual Use*
Add additional rows as needed		
Direct Use	30,757	17,115
Groundwater Recharge	13,977	13,381
Total	44,734	30,496
***Units of measure (AF, CCF, MG)** must remain consistent throughout the UWMP as reported in Table 2-3.*		
NOTES: From 2015 IEUA UWMP and FY 19/20 Recycled Water Annual Report.		

Submittal Table 6-7 Wholesale: Expected Future Water Supply Projects or Programs						
☐	No expected future water supply projects or programs that provide a quantifiable increase to the agency's water supply. Supplier will not complete the table below.					
☐	Some or all of the supplier's future water supply projects or programs are not compatible with this table and are described in a narrative format.					
	Provide page location of narrative in the UWMP					
Name of Future Projects or Programs	Joint Project with other suppliers?		Description *(if needed)*	Planned Implementation Year	Planned for Use in Year Type *Drop Down list*	Expected Increase in Water Supply to Supplier*
	Drop Down Menu	*If Yes, Supplier Name*				
Add additional rows as needed						
Recharge Basin Improvements	*Yes*	*Chino Basin Watermaster*	See Section 4.4.5	2021	All Year Types	11,852 AF
Water Use Efficiency Business Plan	*Yes*	*Retail Agencies, MWD, and other agencies detailed in Section 8*	See Section 4.4.1	2020/2025	All Year Types	9,008 AF
Recycled Water and Intertie	*Yes*	*Western Riverside County Regional Wastewater Authority*	See Section 4.4.3	To be determined	All Year Types	6,000 AFY
RP-5 Liquids Treatment Expansion	*No*		See Section 4.4.3	2020/2025	All Year Types	See Notes
RP-1 Liquids Capacity Recovery and Solids Treatment Expansion	*No*		See Section 4.4.3	2030/2035	All Year Types	See Notes
***Units of measure (AF, CCF, MG)** must remain consistent throughout the UWMP as reported in Table 2-3.*						
NOTES: The projects and schedule detailed in this table are subject to change. Expected Increase in Water Supply is not compatible with some of these projects as they give IEUA the capacity to meet flows and don’t provide water on their own. Recharge Basin improvements increase the amount of stormwater and recycled water that can be recharged to the Chino Basin.						

Submittal Table 6-8 Wholesale: Water Supplies — Actual				
Water Supply	Additional Detail on Water Supply	2020		
Drop down list May use each category multiple times.These are the only water supply categories that will be recognized by the WUEdata online submittal tool		Actual Volume*	Water Quality Drop Down List	Total Right or Safe Yield* (optional)
Add additional rows as needed				
Purchased or Imported Water	From MWD	66,438	Other Non-Potable Water	
Recycled Water	Direct Use and GWR	30,495	Recycled Water	
	Total	96,933		0
****Units of measure (AF, CCF, MG)*** *must remain consistent throughout the UWMP as reported in Table 2-3.*				
NOTES: GWR = Groundwater Recharge. Values from IEUA FY 19/20 Annual Water Use Report and FY19/20 Recycled Water Annual Report.				

OPTIONAL Table 6-8ds: Source Water Desalination

☐	Neither groundwater nor surface water are reduced in salinity prior to distribution.									
Plant Name or Well ID	Plant Capacity	Intake Type *Drop down list*	Source Water Type *Drop down list*	Influent TDS	Brine Discharge *Drop down list*	Volume of Water Desalinated

	Total	153,356	0	156,490	0	157,425	0	160,119	0	160,119	0

****Units of measure (AF, CCF, MG)*** *must remain consistent throughout the UWMP as reported in Table 2-3.*

NOTES:

Submittal Table 7-1 Wholesale: Basis of Water Year Data (Reliability Assessment)			
Year Type	**Base Year** If not using a calendar year, type in the last year of the fiscal, water year, or range of years, for example, water year 1999-2000, use 2000	Available Supplies if Year Type Repeats	
		☐ Quantification of available supplies is not compatible with this table and is provided elsewhere in the UWMP. Location ____________________	
		☑ Quantification of available supplies is provided in this table as either volume only, percent only, or both.	
		Volume Available *	% of Average Supply
Average Year	FY 15/16 - FY 19/20	147,503	100%
Single-Dry Year	FY 15/16	147,477	100%
Consecutive Dry Years 1st Year	FY 15/16	147,477	100%
Consecutive Dry Years 2nd Year	FY 15/16	147,477	100%
Consecutive Dry Years 3rd Year	FY 15/16	147,477	100%
Consecutive Dry Years 4th Year	FY 15/16	147,477	100%
Consecutive Dry Years 5th Year	FY 15/16	147,477	100%

Supplier may use multiple versions of Table 7-1 if different water sources have different base years and the supplier chooses to report the base years for each water source separately. If a supplier uses multiple versions of Table 7-1, in the "Note" section of each table, state that multiple versions of Table 7-1 are being used and identify the particular water source that is being reported in each table. Suppliers may create an additional worksheet for the additional tables.

***Units of measure (AF, CCF, MG)** must remain consistent throughout the UWMP as reported in Table 2-3.*

NOTES: Average year is the average of FY15/16 through FY19/20 wastewater plant flows plus the MWD contract amount from resolution 2014-12-1.

Submittal Table 7-2 Wholesale: Normal Year Supply and Demand Comparison					
	2025	2030	2035	2040	2045 *(Opt)*
Supply totals *(autofill from Table 6-9)*	153,356	156,490	157,425	160,119	160,119
Demand totals *(autofill fm Table 4-3)*	116,716	120,927	124,136	128,212	128,756
Difference	36,640	35,563	33,289	31,907	31,363
NOTES: Normal year based on the average of 2016-2020 conditions.					

Submittal Table 7-3 Wholesale: Single Dry Year Supply and Demand Comparison					
	2020	2025	2030	2035	2040 (Opt)
Supply totals*	153,329	156,462	157,397	160,091	160,091
Demand totals*	118,899	123,938	128,009	133,007	133,571
Difference	34,431	32,524	29,388	27,084	26,519
***Units of measure (AF, CCF, MG)** must remain consistent throughout the UWMP as reported in Table 2-3.*					
NOTES: IEUA considers FY15/16 to represent the single dry year hydrologic conditions. The expected supply is 100% of normal year supply. The IEUA IRP forecasts a regional demand increase of 3.74% by 2040 for a single dry year due to above normal temperature and reduced wet periods (IEUA IRP Appendix E, 2016). Demand increase for prior years are interpolated (from 0.62% in 2015 to 3.74% in 2040). The demand increases for 2045 is assumed to be the same as 2040.					

Submittal Table 7-4 Wholesale: Multiple Dry Years Supply and Demand Comparison						
		2025*	2030*	2035*	2040*	2045* (Opt)

	Difference	33,124	30,710	27,079	24,212	23,635

***Units of measure (AF, CCF, MG) m** ust remain consistent throughout the UWMP as reported in Table 2-3.*

NOTES:
IEUA considers FY15/16 to represent each year of the multiple dry year hydrologic conditions. The expected supply is 100% of normal year supply. The IEUA IRP forecasts a regional demand increase of 5.98% by 2040 for a multi-dry year due to above normal temperature and reduced wet periods (IEUA IRP Appendix E, 2016). Demand increase for prior years are interpolated (from 1.00% in 2015 to 5.98% in 2040). The demand increases for 2045 is assumed to be the same as 2040. The supply and demand for each year of the multi-year drought is expected to be the same.

Revised Surplus/(shortfall)	33,124
Resulting % Use Reduction from WSCP action	0%

Notes: Years 2021 through 2024 are interpolated between the 2020 actual supply and use values and the 2025 projected supply and use for multi-year drought (from Table 7-4). 2020 actual supply is the average year supply from Table 7-1.

Submittal Table 8-1
Water Shortage Contingency Plan Levels

Shortage Level	Percent Shortage Range	Shortage Response Actions (*Narrative description)*
1	Up to 10%	Watch (DCP Level 1: 1-5%)
2	Up to 20%	Warning (DCP Level 2: 6-15%)
3	Up to 30%	Emergency (DCP Level 3: 16-25%)
4	Up to 40%	Critical (DCP Level 4: 26-50%)
5	Up to 50%	
6	>50%	Catastrophic (DCP Level 5: >50%)

NOTES: IEUA's 2020 DCP defined five drought stage conditions noted in the Water Shortage Condition column above. The cross-reference between these shortage stages and the water shortage levels in this table is included in Table 4-1 in the WSCP.

Submittal Table 8-2: Demand Reduction Actions				
Shortage Level	Demand Reduction Actions ***Drop down list*** *These are the only categories that will be accepted by the WUEdata online submittal tool. Select those that apply.*	How much is this going to reduce the shortage gap? *Include units used (volume type or percentage)*	Additional Explanation or Reference *(optional)*	Penalty, Charge, or Other Enforcement? ***For Retail Suppliers Only*** *Drop Down List*
Add additional rows as needed				
1	Expand Public Information Campaign	Minimum 1-5% of water use	Begin profiling high potential customers and develop messaging that will best resonate with those customers	
1	Provide Rebates on Plumbing Fixtures and Devices		SoCal WaterSmart Residential and Commercial Rebates	
1	Provide Rebates for Landscape Irrigation Efficiency		Residential Irrigation Tune-Up, Home Surveys, Landscape Workshops, and Design Services	
1	Provide Rebates for Turf Replacement		Turf Replacement Program	
2	Expand Public Information Campaign	Minimum 6-15% of water use	Introduce influencer marketing; continue targeting high potential customers	
2	Provide Rebates on Plumbing Fixtures and Devices		Implement direct installation programs	
2	Provide Rebates for Landscape Irrigation Efficiency		Expand Landscape Design Services; offer more frequent landscape workshops and home surveys	
2	Provide Rebates for Landscape Irrigation Efficiency		Continue Turf Replacement Program	
3	Expand Public Information Campaign	Minimum 16-25% of water use	Expand profiling and micro-targeting to include mid-range water users; increase influencer marketing	
3	Provide Rebates on Plumbing Fixtures and Devices		Continue base programs; Increase incentive amounts for certain programs; continue smart irrigation direct installation programs	

Submittal Table 8-2: Demand Reduction Actions				
Shortage Level	Demand Reduction Actions ***Drop down list*** *These are the only categories that will be accepted by the WUEdata online submittal tool. Select those that apply.*	How much is this going to reduce the shortage gap? *Include units used (volume type or percentage)*	Additional Explanation or Reference *(optional)*	Penalty, Charge, or Other Enforcement? ***For Retail Suppliers Only*** *Drop Down List*
3	Provide Rebates for Landscape Irrigation Efficiency		Continue Stage 2 Actions	
3	Provide Rebates for Turf Replacement		Increase incentive amounts	
4, 5	Expand Public Information Campaign	Minimum 24-50% of water use	Strengthen message of urgency and community call to action	
4, 5	Provide Rebates on Plumbing Fixtures and Devices		Continue increase incentives and smart irrigation direct installation programs	
4, 5	Provide Rebates for Landscape Irrigation Efficiency		Continue Stage 2 Actions	
4, 5	Provide Rebates for Turf Replacement		Increase incentive amounts	
6	Expand Public Information Campaign	Minimum 50% of water use	Implement catastrophic messaging, announce essential use only	
6	Provide Rebates on Plumbing Fixtures and Devices		Only offer indoor plumbing and property leak detection programs.	
6	Provide Rebates for Landscape Irrigation Efficiency		Suspend all programs	
6	Provide Rebates for Turf Replacement		Suspend all programs	

NOTES: Each IEUA retail agency is responsible for enforcing local water waste ordinances; details of the restrictions by agency can be found in the 2020 DCP and each individual retail agency's 2020 WSCP. Additional details on drought response actions can be found in the IEUA's 2020 DCP and WSCP.

Submittal Table 8-3: Supply Augmentation and Other Actions			
Shortage Level	Supply Augmentation Methods and Other Actions by Water Supplier ***Drop down list*** *These are the only categories that will be accepted by the WUEdata online submittal tool*	How much is this going to reduce the shortage gap? *Include units used (volume type or percentage)*	Additional Explanation or Reference *(optional)*
Add additional rows as needed			
1 through 6	Other Actions (describe)	Undetermined amount	IEUA is always looking for opportunities to explore additional recycled water connections to increase supply.
6	Other Purchases	Up to 93,283 AFY (MWD Contract Amount)	Purchase MWD Tier 2 Imported Water
NOTES: MWD Contract Amount from Resolution No. 2014-12-1			

Submittal Table 10-1 Wholesale: Notification to Cities and Counties (select one)		
☑	Supplier has notified more than 10 cities or counties in accordance with Water Code Sections 10621 (b) and 10642. **Completion of the table below is not required. Provide a separate list of the cities and counties that were notified.**	
Table 10-1	Provide the page or location of this list in the UWMP.	
☐	Supplier has notified 10 or fewer cities or counties. **Complete the table below.**	
City Name	60 Day Notice	Notice of Public Hearing
Add additional rows as needed		
City of Chino	Yes	Yes
City of Chino Hills	Yes	Yes

NOTES: In addition, the following agencies were also given a 60 Day Notice and Notice of Public Hearing: Chino Basin Water Master, Chino Basin Desalter Authority, Local Agency Formation Commission for San Bernardino County, Metropolitan Water District, Santa Ana Regional Water Quality Control Board, Santa Ana Watershed Project Authority, Three Valleys Municipal Water District, West Valley Water District, and the Water Facilities Authority. Notification letters were sent out in November 2020, April 2021, and May 2021. Copies of these notification letters are included in Appendix E of the 2020 UWMP.		

Appendix D

IEUA Resolution 2021-6-10 2020,
Adopting the UWMP, 2020 WSCP

RESOLUTION NO.2021-6-10

A RESOLUTION OF THE BOARD OF DIRECTORS OF THE INLAND EMPIRE UTILITIES AGENCY (IEUA), SAN BERNARDINO COUNTY, CALIFORNIA, ADOPTING THE 2020 URBAN WATER MANAGEMENT PLAN, 2020 WATER SHORTAGE CONTINGENCY PLAN, AND APPENDIX G AS AN ADDENDUM TO THE 2015 URBAN WATER MANAGEMENT PLAN

Whereas, the California Legislature enacted Assembly Bill 797, (Water Code Section 10610 et seq., known as the Urban Water Management Planning Act) during the 1983-1984 Regular Session, and as amended subsequently, which mandates that every urban water supplier providing water for municipal purposes either directly or indirectly to more than 3,000 customers or supplying more than 3,000 acre-feet of water annually, prepare an Urban Water Management Plan at least once every five years; and

Whereas, the Urban Water Management Planning Act requires the preparation and adoption of a Water Shortage Contingency Plan, in accordance with prescribes requirements; and

Whereas, the Urban Water Management Planning Act specifies the requirements and procedures for amending and adopting such Urban Water Management Plans; and

Whereas, the Inland Empire Utilities Agency* is a wholesale supplier of water for 242-square miles in the western portion of San Bernardino; and

Whereas, pursuant to Section 10620 of the Urban Water Management Planning Act, the Inland Empire Utilities Agency has prepared the 2020 Urban Water Management Plan, 2020 Water Shortage Contingency Plan, and Appendix G as an addendum to the 2015 Urban Water Management Plan; and

Whereas, the Board of Directors of the Inland Empire Utilities Agency has duly reviewed, discussed, and considered the 2020 Urban Water Management Plan, 2020 Water Shortage Contingency Plan, and Appendix G as an addendum to the 2015 Urban Water Management Plan.

NOW, THEREFORE, BE IT RESOLVED, DETERMINED AND ORDERED BY THE INLAND EMPIRE UTILITIES AGENCY AS FOLLOWS:

Section 1. The 2020 Urban Water Management Plan is hereby adopted; and

Section 2. The 2020 Water Shortage Contingency Plan is hereby adopted; and

Section 3. The addendum of Appendix G to the 2015 Urban Water Management Plan is hereby adopted; and

Section 4. The General Manager is hereby authorized to file an electronic copy of the 2020 Urban Water Management Plan, 2020 Water Shortage Contingency Plan, and Appendix G to the 2015 Urban Water Management Plan with the State Department of Water Resources within 30 days following its adoption and no later than July 1, 2021.

Section 5. The General Manager is hereby authorized to file a CD or hardcopy of aforementioned plans with the California State Library no later than 30 days after its adoption.

Section 6. The General Manager is hereby authorized to submit an electronic copy or a CD or hardcopy of the adopted aforementioned plans to any city or county in which the suppliers provide water no later than 30 days after its adoption.

Section 7. The General Manager is hereby authorized and directed to implement the adopted aforementioned plans, including recommendations to the Board of Directors regarding necessary procedures, rules, and regulations in an effort to carry out effective and equitable water programs.

Section 8. The Resolution shall take effect upon adoption.

ADOPTED this 16th day of June 2021.

Jasmin A. Hall, President of the Inland Empire Utilities Agency* and the Board of Directors thereof

ATTEST:

Steven J. Elie, Secretary/Treasurer of the Inland Empire Utilities Agency* and of the Board of Directors thereof

The undersigned certifies that this is a true copy as on file in the permanent records of the Agency. This stamp must be in purple ink to constitute a certified copy.

SUBJECT: 2020 Urban Water Management Plan Update

Dear Agency Representative:

The Inland Empire Utilities Agency (IEUA) is undertaking the review, update, and revision of its Urban Water Management Plan (UWMP). The Urban Water Management Planning Act requires every urban water supplier of a certain size to prepare and adopt an UWMP at least once every five years. The UWMP is a planning document in which water suppliers evaluate and compare their water supply and reliability to their existing and projected demands. IEUA is in the process of preparing the 2020 UWMP Update.

As an urban water supplier, the IEUA is required pursuant to Section 10620(d)(3) of the California Water Code to coordinate with water management agencies, relevant public agencies, and other water suppliers regarding the preparation of the UWMP. Pursuant to Section 10621(b) of the California Water Code, the IEUA will be reviewing the UWMP and will make amendments or changes, as appropriate. Based on the IEUA's current schedule, we expect to have a draft available for public review by April 2021, at which point your agency will receive notification that the draft UWMP is available for public review and comment.

The IEUA invites you to submit written comments in anticipation of the development of our 2020 UWMP Update within the next 30 days to IEUA. If your agency would like to learn more about the UWMP, please feel free to contact me at 909.993.1698 or jaguilar@ieua.org.

Sincerely,

J. Aguilar

Joshua Aguilar
Senior Engineer

NOTICE OF PUBLIC HEARING
BY THE BOARD OF DIRECTORS OF THE INLAND EMPIRE UTILITIES AGENCY*
TO ADOPT THE 2020 URBAN WATER MANAGEMENT PLAN (UWMP),
ADDENDUM OF APPENDIX G TO THE 2015 UWMP,
AND WATER SHORTAGE CONTINGENCY PLAN
SAN BERNARDINO COUNTY, STATE OF CALIFORNIA

NOTICE IS HEREBY GIVEN that the Board of Directors of the Inland Empire Utilities Agency intends to hold a public hearing for adoption of the 2020 Urban Water Management Plan (UWMP), Addendum of Appendix G to the 2015 UWMP, and Water Shortage Contingency Plan.

NOTICE IS FURTHER GIVEN that said public hearing will be held on the following date and time for the purpose of hearing any and all public testimony on the above-stated issue.

DATE: Wednesday, June 16, 2021 – 10:00 a.m.

The meeting will be accessible via teleconference at:
Phone Number: (415) 856-9169 / Conference ID: 811 284 110#

In the effort to prevent the spread of COVID-19, until further notice, the Inland Empire Utilities Agency will hold all Board and Committee meetings by video and audio conference. As of the posting/publication of this notice, it is anticipated that the public hearing will be conducted virtually by video and audio conference. (Please visit www.ieua.org for the most up-to-date information regarding meeting participation.) There will be no public location available to attend the meeting; all interested persons are invited to participate in the public hearing and provide comments regarding the proposed 2020 UWMP, Addendum of Appendix G to the 2015 UWMP, and Water Shortage Contingency Plan by calling into the number provided above. The public may also view the meeting live through the Agency's website at www.ieua.org. Oral statements will be heard, but for the accuracy of the record all important testimony should be submitted in writing. Written comments may be emailed to the Board Secretary/Office Manager Denise Garzaro at dgarzaro@ieua.org no later than 24 hours prior to the scheduled meeting time. Comments submitted in advance will be read into the record during the hearing.

NOTICE IS FURTHER GIVEN that the 2020 UWMP, Addendum of Appendix G to the 2015 UWMP, and Water Shortage Contingency Plan will be available on the Agency's website at www.ieua.org and via hard-copy upon request in Spring of 2021, no less than two weeks prior to the public hearing. All interested parties are noticed and invited to submit comments and consult with the Agency regarding its forthcoming 2020 UWMP, Addendum of Appendix G to the 2015 UWMP, and Water Shortage Contingency Plan to the Strategic Planning and Resources Department, attention Joshua Aguilar at jaguilar@ieua.org. For additional information regarding the 2020 UWMP, Addendum of Appendix G to the 2015 UWMP, and Water Shortage Contingency Plan, please contact Senior Engineer, Joshua Aguilar at (909) 993-1694.

SUBJECT: Posting of the 2020 Urban Water Management Plan, Addendum of Appendix G to the 2015 UWMP, and 2020 Water Shortage Contingency Plan

Dear Agency Representative:

The Inland Empire Utilities Agency (IEUA) is inviting public review and comment on its Draft 2020 Urban Water Management Plan (UWMP). The Plan includes an updated Addendum of Appendix G to the 2015 UWMP and 2020 Water Shortage Contingency Plan (WSCP).

In compliance with California Water Code (§10610-10656, §10608 and §10632) the UWMP and WSCP are required to contain detailed evaluations of water supplies necessary to reliably meet demands of the California Water Code to coordinate with water management agencies, relevant public agencies, and other water suppliers regarding the preparation of the UWMP and other plans.

All plan documents are now available on IEUA's website here: https://www.ieua.org/read-our-reports/other-reports/.

Comments must be received no later than **5:00 p.m. Monday, May 24, 2021** and sent to the attention of Joshua Aguilar, 909.993.1698 or jaguilar@ieua.org.

If you or your agency would like more information on IEUA's UWMP, Addendum, or WSCP, please contact me.

Sincerely,

J. Aguilar

Criteria 4

Disadvantaged Community. A "Disadvantaged Community" (DAC) is a community with a median household income less than 80 percent of the statewide average.

SELECT ONE

"Disadvantaged Community" status was determined using one of the methods listed below:

1. IRWM DAC Mapping tool https://gis.water.ca.gov/app/dacs/

☐ If using the IRWM DAC Mapping Tool, include a screen shot from the tool showing that the service area is considered a DAC.

2. 2020 Median Income

☐

California Median Household Income*		Service Area Median Household Income	Percentage of Statewide Average	**Eligible for Exclusion? Y/N**
2020	**$75,235**		0%	YES

*California median household income 2015 -2019 as reported in US Census Bureau QuickFacts.

SB X7-7 Table 4-C.4: Process Water Deduction Eligibility

Criteria 4

Disadvantaged Community. A "Disadvantaged Community" (DAC) is a community with a median household income less than 80 percent of the statewide average.

SELECT ONE

"Disadvantaged Community" status was determined using one of the methods listed below:

☐ **1. IRWM DAC Mapping tool https://gis.water.ca.gov/app/dacs/**

If using the IRWM DAC Mapping Tool, include a screen shot from the tool showing that the service area is considered a DAC.

☑ **2. 2020 Median Income**

California Median Household Income		Service Area Median Household Income	Percentage of Statewide Average	**Eligible for Exclusion? Y/N**
2020 Compliance Year - Process Water Deduction Eligibility				
2020	$80,440	$92,773	115%	NO
